A second TRC analyzer is recommended at each CSO facility for the final discharge point. This will facilitate tweaking the setpoint for the upstream TRC analyzer discussed above and thereby improve compliance with the TRC goal at the discharge. The effluent TRC analyzer results can either be manually considered in tweaking the upstream TRC set point, or if GLWA prefers, it could be used automatically to adjust the upstream TRC setpoint. For example, if it is desired to target a 1 mg/L effluent TRC and the measured effluent TRC is 2 mg/L, and the upstream TRC setpoint was 5 mg/L, the upstream TRC setpoint could be automatically decreased by this 1 mg/L differential to 4 mg/L. And if the measured effluent TRC is 0 mg/L

the upstream TRC setpoint could be increased in increments (e.g., 0.5 or 1 mg/L) with adequate time delays between adjustments, until the effluent TRC reaches 1 mg/L.

Having online TRC analyzers will not only allow effluent coliform and effluent TRC to be controlled to a tighter range than is possible through manual measurements and feed rate adjustments but it will also free up time spent chemically analyzing TRC during a storm so that operators are able to spend their time attending to other needs and monitoring the facility.

Automated control systems require that the flow measurement and TRC analyzers be well maintained and calibrated. With eight active (i.e., excluding Seven Mile) CSO facilities and the recommendation for two TRC analyzers per facility, it is recommended that a single entity, whether internal or contracted, be responsible for maintaining the TRC analyzers to ensure these instruments are operating properly.

Operator training will be critical for successful transition to automated dosing. It is important that the training convey, and operators implement the following:

- The concept of dose being in terms of a concentration (i.e., mg/L) because of the correlation between dose and residual chlorine.
- Regular measurement and entry of sodium hypochlorite strength into the control system. This is important because twice the feed rate is required for the same TRC if the sodium hypochlorite has degraded from 10 percent to 5 percent. The degradation of sodium hypochlorite is unique compared to most other chemicals used in wastewater treatment.

Good operator training will also facilitate operation in manual mode should the TRC analyzer and or flow measurement be out of service. If the TRC analyzer is out of service, the automation system should be designed to allow the flow pacing control to continue. Manual adjustments of the dose should primarily be based on sampling at the upstream TRC sample point with the effluent TRC sample point being a secondary consideration due to the time delay issue discussed above.

5.2.3.3 Review of TRC Analyzer Manufacturers

There are multiple manufacturers with successfully operating TRC analyzers in wastewater applications. The primary types are colorimetric and amperometric. Some require reagents and some are reagent-less. The decision of which analyzer to choose should be based on consideration of some of the attributes of one analyzer versus another and discussions with personnel at other WRRFs or CSO facilities regarding their satisfaction with the equipment. The following are examples of manufacturers that GLWA may want to consider:

- Swan
- Evoqua Wallace & Tiernan
- Chemsan
- Hach
- Rosemount

GLWA may wish to pilot several to identify a preferred analyzer. Once an analyzer is proven at one facility, it is recommended that all the facilities standardize on this TRC analyzer to simplify calibration and maintenance, and to facilitate operators rotating between CSO facilities.

5.2.3.4 Identified Alternatives

Based on the discussion above, the identified alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

5.2.4 Reduce Cost Associated with Large Quantity of Chemical Induction Mixers

5.2.4.1 Introduction

Based on GLWA personnel input and observations during the site visits, reducing the quantity of induction mixers, especially at the facilities with a large number of induction mixers, is desired for the following reasons:

- The mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance
 - Manufacturer maintenance costs are higher than equipment that can be maintained in house
 - Shipping adds costs
 - Turnaround of the Evoqua induction mixers utilized at the majority of GLWA's CSO facilities takes months before the mixer is returned to service.
- Splitting chemical feed to multiple mixers complicates the chemical feed system (e.g., additional back pressure valves, flow metering, pressure monitoring, and piping)

For these reasons, a mixer evaluation was conducted under CS-299 that is applicable to multiple facilities. The importance is greatest at the facilities with the most mixers as follows:

- Conner Creek: 60 induction mixers
- Baby Creek: 32 induction mixers
- Leib: 18 induction mixers

The next largest number of mixers is St. Aubin with seven induction mixers. After that there are only two to four induction mixers per facility and thus the number of mixers at these facilities is not as significant.

The recommendations for facilities requiring a mixer evaluation are presented here and referenced in the facility-by-facility section because this section applies to multiple facilities.

The following alternatives for reducing costs of mixers at Conner Creek, Baby Creek and Leib are provided in the following list and described in the following sections:

- 1) Use an equivalent, less costly induction mixer (potentially Gas Mastrrr induction mixers) for all facilities
- 2) Reduce quantity of induction mixers
- 3) Use a different type of mixer (i.e., vertical shaft)

5.2.4.2 Comparison of Water Champ and Gas Mastrrr Induction Mixers

There are two manufacturers of induction mixers at the CSO facilities, Evoqua Water Champs and Mastrrr Company Gas Mastrrr induction mixers. There are 123 Water Champs at six CSO facilities compared to

only four Gas Mastrrr mixers at two CSO facilities, therefore the majority of GLWA's experience is with Water Champs. The Water Champs have had a higher purchase price, and it is desired to determine if the two manufacturers can be competitively bid when replacing mixers. Therefore, it was requested that the mixing intensity, as defined by the G-value, be compared for the Gas Mastrrr units versus the Water Champs for a given horsepower (hp) unit.

G-Value: Information was gathered on the cone of influence and corresponding mixing energy (referred to as "G-value") for both manufacturers and it was confirmed that Gas Mastrrr induction mixers provide similar G values to Water Champs for a given hp model.

Modifications for Installation of Gas Mastrrr Mixers: The local Gas Mastrrr representative visited a couple of the GLWA facilities where Water Champs are used and concluded the guide rails and controls would be reusable but new attachment brackets may be required.

Comparison of Maintenance Work Order History: Currently, GLWA has Gas Mastrrr induction mixers at Hubbell-Southfield (3) and Seven Mile (1). However, given the hydraulic issues limiting discharge from Seven Mile, the three Gas Mastrrr induction mixers at Hubbell-Southfield are the primary basis for forming opinions on relative reliability. For comparison there are a combined 123 Water Champ induction mixers at six of the CSO facilities. An evaluation of the number of maintenance work orders for the chemical induction mixers over the past five years is presented in Table 5-8 (as presented in the Maintenance Work Order Review for Facilities Assessment Task report). Although there is a large majority of Water Champ mixers, the annual average number of work orders per mixer is similar.

Table 5-8. Review of Chemical Induction Mixer Work Orders by CSO Facility

CSO Facility	Mixer Manufacturer and Model	Number of Installed Mixers	Total Number of WOs for Chemical Induction Mixers	Average Number of WOs per Mixer Over a 5-Year Period
Baby Creek	Evoqua (Water Champ)	32	38	1.2
Belle Isle	Evoqua (Water Champ)	4	0	0
Conner Creek	Evoqua (Water Champ)	60	51	0.9
Hubbell Southfield	Gas Mastrrr	3	5	1.7
Leib	Evoqua (Water Champ)	18	41	2.2
Puritan-Fenkell	Evoqua (Water Champ)	2	0	0
Seven Mile	Gas Mastrrr	1	0	0
St. Aubin	Evoqua (Water Champ)	7	15	2.1
Total		127	150	1.2

Repair Center: Another consideration for the mixers is the location of the repair center and the associated shipping costs. Gas Mastrrr indicated a local repair shop in Detroit area would be used, whereas Evoqua's repair center was historically located in Louisiana. As of late 2020, however, a repair facility is reportedly located in Belleville, Michigan.

Cost Comparison: Pricing was received from both manufacturers that varied with the number of units purchased, whether existing units were exchanged, and with and without explosion-proof motors. Table 5-9 provides a cost comparison of the two sizes for which explosion-proof motors were quoted by both manufacturers, assuming no existing units are exchanged, and using their bulk pricing discount assuming ten mixers are purchased at a time. The Gas Mastrrr mixers were quoted at 70 percent to 72 percent of the

Water Champ mixers. It is possible that Evoqua will improve their Water Champ pricing in a true competitive bid situation.

Table 5-9. Cost Comparison Between Water Champ and Gas Masterrr Induction Mixers

Motor hp	Water Champ (\$/mixer)	Gas Masterrr (\$/mixer)
15	\$37,000	\$26,300
20	\$40,000	\$29,300

Based on the G factor, the apparent interchangeable use of the existing guiderails and controls, work order history on reliability, and a comparison of quotes, GLWA can competitively bid Gas Masterrr mixers and Water Champ mixers when replacing mixers going forward. The attachment brackets, and any other appurtenances as required to utilize the alternative manufacturer at a given location, can be specified to be included in the bid by that company to ensure all cost for switching to an alternative manufacturer are accounted for.

5.2.4.3 Reduce Quantity of Existing Mixers

This section evaluates the feasibility of reducing the number of mixers at each facility, now that many years of various storm events and operating experience has been obtained.

To understand the basis for the current number of mixers at each facility, it is helpful to review design documents. The basis of design for Conner Creek states:

"The number and size of the mixers was based on data collected during a mixing test conducted by Alden Research Laboratory, Inc in July 1999. The purpose of the test was to define the volume of water affected by the mixer at the design flow...

Mixing effectiveness was determined by measuring the concentration of a fluorescent tracer at two vertical planes, 10 feet (ft) and 58 ft downstream from the impeller of the mixers. The velocity and tracer concentration data were normalized by dividing the measured values by the theoretical average value. The theoretical channel velocity was 3 fps...

At the 10-ft vertical plane, a "uniform mix" was observed to occur within a cross-sectional area of approximately 24 square ft, which was equivalent to 33% of the total cross-sectional area. At the 58-ft vertical plane, the fluorescent tracer dye was observed throughout the 10-ft x 8.5-ft cross sectional flow path. Additionally, at the 58-ft vertical plane, there was an obvious gradation of tracer concentration, the highest concentration being at the water surface. The cross-sectional area of the test channel was approximately 1/6 of the full-scale channel, therefore, it is recommended to equip each of the screening/mixing channels with six, 20-hp induction-type mixers."

In summary, the mixer achieved non-uniform tracer dispersion across the entire cross-sectional area of the test channel at 58 ft and uniform dispersion across 33 percent of the cross-sectional area at 10 ft, the only two vertical planes tested. The basis, and significance if any, of the 58 ft vertical plane sampled is not explained. If one were to extrapolate the dispersion being across 33 percent of the cross-sectional area at 10 ft, then it is possible that dispersion occurred across the whole cross-sectional area at 30 ft. It is not apparent from the basis of design report that interpretation of the dispersion results was used in choosing the number of mixers for full-scale design. Instead, it appears that the determination of how many mixers to incorporate into the full-scale design at Conner Creek was simply a multiplication of the test channel cross-sectional area to the full-scale facility cross-sectional area. This raises the question that if they had instead chosen a pilot facility that was 1/4th the size of the full-scale facility, would they have designed four mixers rather than six mixers per mixing zone?

Computational Fluid Dynamics (CFD) is a powerful hydraulic analysis and design tool that was not available when the CSO facilities were designed. A primary issue with the physical model approach previously taken is how to interpret and apply the test results to design. With CFD modeling, the dispersion of chemical can be determined with relatively high certainty for any given number of mixers and mixer locations. Thus, the required number of mixers can be determined. A required input of CFD modeling is the mixing characteristics of each mixer to be modeled. Therefore, this information would be required from the mixer manufacturers.

CFD modeling is recommended for Baby Creek, Conner, Creek, and Leib, and if desired St. Aubin as well although only a two-mixer reduction would be anticipated there. The small number of mixers at the remaining facilities minimizes potential mixer reductions at those facilities, especially considering the benefit of some redundancy should a mixer become non-operational and not be available during a CSO event. For example, at a facility with only two, three, and four mixers, one mixer out of service represents a 50 percent, 33 percent, and 25 percent reduction in overall facility mixing capacity, respectively. The implications of one or two mixers being out of service at the three facilities with the largest number of mixers are much smaller.

Consultation with the CFD modeler should occur during scoping of the CFD modeling project to decide on the best modeling approach. It should also be determined whether the peak design capacity of the facility is the only condition to be modeled or whether any lower flow rates should also be modeled. The following is a preliminary list for consideration:

- Modeling of the existing number and size of mixers to develop a baseline.
- Modeling with fewer of the existing mixers in existing locations to determine what mixers if any could be eliminated.
- Modeling with fewer of the existing mixers but in optimized locations. Utilization of existing floor openings should be given first preference. If significant benefits are anticipated with alternative mixer locations then interferences and cost implications of a new floor penetration, hatch, and mixer removal infrastructure should be considered when selecting alternative locations to model.
- Modeling of larger (e.g., higher hp) induction mixers. This could be done in conjunction with one or both of the previous two bullets.

Although not recommended because it would rely more on trial and error and extensive sampling, an alternative to CFD modeling would be to remove mixers in one mixing zone and sample at enough points at the discharge end of the mixing zone to analyze the adequacy of chlorine dispersion. This could be accomplished by installing submersible sample pumps or sample pipes connected to self-priming sample pumps located on the operating level. A significant number of sample pumps or sample pipes would be required to adequately cover the cross section leaving the mixing zone. Initial testing could be conducted with the currently installed number of mixers to develop a baseline. Then testing could be conducted with one or more mixers removed. The intermittent and highly variable nature of CSOs make full-scale testing much more challenging than would be the case at a continuously operating wastewater treatment plant. Drawbacks of this approach compared to CFD modeling include:

- The design capacity of the facilities corresponds to a very infrequent event with a flow far in excess of typical peak storms. Therefore, testing at lower flows is unlikely to be fully indicative of the adequacy of mixing at peak design flow.
- The optimum positioning of mixers would be by trial and error and would be limited to positions on existing rails.
- Testing of each configuration would likely need to occur during multiple events, with an emphasis on capturing data during large events. This could require testing in one configuration (e.g., number of

mixers and mixer positioning) for a year or more depending on how soon a peak event occurs after setting a given configuration.

- The lack of access favors installing a matrix of sample points to provide adequate sampling. The associated piping would likely accumulate debris passing through screening and require periodic cleaning.

Without CFD modeling there is not a real basis for estimating whether the number of mixers can be reduced and by how much. Therefore, assumptions are required for estimating the costs of this alternative. Table 5-10 summarizes the assumptions for cost estimating this alternative.

Table 5-10. Reduced Number of Induction Mixers Alternative Summary

Facility	No. of Mixing Channels	Existing Number of Mixers Per Mixing Zone	Existing Total Number of Mixers	Assumed Number of Mixers Per Mixing Zone	Assumed Total Number of Mixers	Cost Per Mixer ^a	Cost Savings per Facility Using Reduced No. of Mixers
Baby Creek	8	4	32	2	16	\$50,000	\$800,000
Conner Creek	10	6	60	4	40	\$50,000	\$1,000,000
Leib	4	4	16 ^b	2	8 ^b	\$50,000	\$400,000

^a Based on existing Water Champ induction mixers with explosion-proof motors (Table 5-9), with a contingency and installation cost.

^b The two prechlorination mixers are not included in this evaluation and would remain.

5.2.4.4 Alternative Mixer Technology – Vertical Shaft Mixer

Vertical shaft mixers are a more common type of mechanical mixer at wastewater and water treatment plants than induction mixers. Vertical shaft mixers are typically very low maintenance and highly reliable. Figure 5-3 shows a vertical shaft mixer potentially applicable to Conner Creek.

Figure 5-3. Vertical Shaft Mixer

The primary concern with this proven mixing technology if applied to a CSO facility is the potential for ragging and questions regarding whether that would cause damage to the mixer or result in significantly greater maintenance. Maintenance on vertical shaft mixers for this application would consist of:

- Change oil every 6 months to a year (potentially less frequent if the oil is sampled and analyzed).
- Grease bearings at the same time as oil changes. There is an upper and a lower bearing in the gearbox.
- Removal of rags from the shaft and impellers periodically. The amount of ragging will vary with CSO facility due to differences in screen openings and the quantity of screenings present in the CSO.
- Service the steady bearing every two years. This is a floor mounted bearing. Steady bearings are custom made for the application and their design will vary. An example of steady bearing is shown in Figure 5-4. Given the presence of solids, this application may involve a water flush to the lower bearing similar to pump seal water in order to maximize bearing life.

For the Leib facility, the belowground location of the mixer chamber and limited headspace would require significant structural modifications above the mixing chambers to allow the vertical shaft mixer to be installed and removed. Based on these constraints, the vertical shaft mixer is not further considered at the Leib facility and only induction mixer alternatives will be considered at Leib.

In addition to vertical shaft mixers typically being very low maintenance and highly reliable, another advantage of vertical shaft mixers over submersible mixers are the first two maintenance tasks noted above are on components located on the operations floor.

Drawings, facility design flows, and other relevant information were provided to Philadelphia Mixing Solutions and recommendations and budgetary pricing requested for the three facilities with the largest number of induction mixers. The three facilities were Conner Creek, Baby Creek, and Leib. The next largest number of mixers is St. Aubin with seven induction mixers. If successfully implemented at the facilities with the largest number of induction mixers, then replacement of six induction mixers with vertical shaft mixers downstream of screening could be considered at St. Aubin in the future. The seventh induction mixer at St. Aubin is a prechlorination mixer upstream of screening and would be assumed to remain. There are only one to four induction mixers per facility at the remaining facilities with induction mixers and thus the number of mixers at these facilities is not significant enough to warrant replacement with vertical shaft mixers.

- Philadelphia Mixing Solutions selected mixer sizes to rapid mix sodium hypochlorite based on the mixing zone size and configuration and the design peak flow of the facility. The proposed vertical shaft motor hp per mixing zone exceeds that of the existing induction mixers. The fact that the energy demand is concentrated in fewer larger motors will require changes to the power distribution thereby affecting capital cost. However, the intermittent nature of the CSO facilities is expected to minimize the life-cycle energy cost differences between the two technologies. Two features were proposed by Philadelphia Mixing Solutions to address the concerns about ragging:
 - 1) Steady bearing. This is provided to prevent shaft deflection from rag accumulation on the shaft and impeller and resulting stress on the upper bearings.
 - 2) Curved-blade turbine impeller intended to minimize ragging. The impeller is illustrated in Figure 5-5.

Figure 5-5. Curved-blade Turbine Impeller

- The mixers are designed to run during fill/drain operations, i.e., as the water level rises, or drops back down, through the level of the impeller(s). Although the mixer could run dry for short periods of time, the manufacturer does not recommend running them dry for any extended period of the time because

if solids are present in the steady bearing, the wear sleeve could be damaged. The mixers at Conner Creek and Baby Creek would have three impellers per shaft to provide rapid mixing at multiple depths. The mixers could run with any combination of impellers being above or below the water level due to water level variation during an event. Two mixers were proposed at each existing mixing zone for all three facilities. Table 5-11 summarizes the vertical shaft mixer concept for the two feasible facilities.

Table 5-11. Vertical Shaft Mixer Alternative

Facility	No. of Mixing Channels	Mixers Proposed Per Channel	Total Mixers Required	Cost Per Mixer	Mixer Equipment Cost Per Facility	Per Mixer Motor hp	Total Mixer Motor hp
Baby Creek	8	2	16	\$70,000	\$1,122,000	50	800
Conner Creek	10	2	20	\$79,000	\$1,578,000	75	1,500

- This alternative would cut the number of mixers from 60 to 20 at Conner Creek and from 32 to 16 at Baby Creek. Vertical baffling was recommended by the mixer manufacturer at each mixer location to facilitate turbulence rather than bulk laminar liquid rotation. Mixer locations (red) and proposed baffles (green) for each facility are illustrated in Figure 5-6, Figure 5-7 and Figure 5-8.

Figure 5-6. Vertical Shaft Mixers (Profile) Conceptual Implementation - Conner Creek

Figure 5-7. Vertical Shaft Mixers (Plan) Conceptual Implementation - Baby Creek

Figure 5-8. Vertical Shaft Mixers (Plan) Conceptual Implementation – Leib (Shown for reference only)

The in-series orientation at Conner Creek and Baby Creek would have the added advantage of providing partial redundancy because rapid mixing, at half the normal energy input, would continue to occur if there was a problem preventing operation of one mixer in that pair.

The advantages and disadvantages of the vertical shaft mixer is as follows:

Advantages:

- Typically very low maintenance
- Typically highly reliable
- Components requiring routine maintenance are located on the operations floor
- Cuts the number of mixers from 60 to 20 at Conner Creek and from 32 to 16 at Baby Creek
- Motor and gear drive are serviceable thereby minimizing the need to ship components to the manufacturer's maintenance facility
- Mixer can be run over the range of water levels during an event. This compares to the need to start and stop induction mixers installed at different elevations depending on water level.
- The in-series orientation at Conner Creek and Baby Creek would provide partial redundancy if one mixer were out of service (i.e., 50 percent mixing intensity)

Disadvantages:

- Requires steady bearing on the floor of the mixing zone due to the application. This is less typical for vertical shaft mixers and the associated maintenance requirements are site-specific and difficult to predict. Maintenance on these requires
- Steady bearing may require seal water to flush debris which could shorten the life of the bearing.
- Requires periodic removal of rags and debris from the shaft and impeller. CSO is not a typical application for vertical shaft mixers and the associated maintenance requirements are site-specific and difficult to predict.

- Requires some baffling additions. The head loss associated with these is anticipated to be insignificant but this should be verified during design.
- Higher total hp than the existing induction mixers. However, the intermittent nature of the CSO facilities is expected to minimize the life-cycle energy cost differences between the two technologies.

5.2.4.5 Alternative Evaluation

The 20-year life-cycle costs are presented in the alternatives evaluations contained in the Disinfection sections of the Baby Creek (Section 6.2.2) and Conner Creek (Section 8.2.2). These are the only two facilities where the vertical shaft mixer is considered feasible. The alternatives evaluation also includes the anticipated annual maintenance costs associated with each mixer.

It is recommended that CFD modeling be conducted as described herein to determine by how much the number of induction mixers can be reduced.

5.2.5 Total Chlorine Residual Reduction

TRC reduction (i.e., dechlorination) is currently not required for CSO discharges at any of the existing CSO facilities. However, the WWMP evaluated the size and location of dechlorination facilities in the section on potential future regulations. The capital cost estimates from the WWMP are presented in Table 5-12. GLWA does not anticipate a TRC requirement in the next 20 years while the Long Term CSO Control Plan is being executed because of finite resources to support other capital expenditures.

Table 5-12. TRC Reduction Capital Cost Estimates From the WWMP

CSO Facility	Estimated Capital Cost ^a (ENR CCI 11500 2019)
Baby Creek SDF	\$ 22.5 million
Conner Creek RTB	\$ 46.2 million
Hubbell Southfield RTB	\$ 16.5 million
Leib SDF	\$ 10.8 million
Puritan-Fenkell RTB	\$ 7.7 million
Oakwood RTB	\$ 10.6 million
Puritan-Fenkell RTB	\$ 7.7 million
Seven Mile RTB	\$ 7.3 million
St Aubin SDF	\$ 5.2 million

^a WWMP estimated TRC reduction capital costs, however these capital costs are not anticipated in the 20 year planning period of this report.

5.3 Electrical

5.3.1 CSO-Wide Lighting Replacement Project

A light-emitting diode (LED) Lighting Replacement project, conducted under Job Order Contract (JOC) No. 9, was completed in late 2020. The project consisted of replacing the originally installed fluorescent and sodium vapor light fixtures with new energy-efficient LED lighting fixtures at all CSO facilities. This project included a 7-year warranty on the new fixtures. Because of this recent project, the existing lighting at the facilities was not evaluated under CS-299.

New and additional lighting locations were discussed with O&M staff at each facility where lighting improvements are desired to better perform maintenance and daily operations activities. If applicable, the locations for additional lighting are presented in the Electrical section of each facility.

5.3.2 Power Quality Monitoring

GLWA currently has an ongoing power monitoring project for all CSO facilities. The project consists of installing a Schneider power monitoring system, which will enable GLWA to monitor the power quality of the electrical systems at each facility. The system will detect abnormal conditions, locate circuit insulation faults, and monitor the electrical equipment. It will allow GLWA to efficiently identify and track power event causes, patterns and system capacity to avoid overloads and failures. The power monitoring system has the ability to capture and record power monitoring data which can be used to troubleshoot and address current and future power issues at the facility.

5.4 Instrumentation and Control

5.4.1 Introduction

There are a number of I&C-related common improvements that could be made at the CSO facilities to standardize their operation, reduce maintenance costs and improve operations. The needs are described in this section and referenced, as appropriate, in the facility-by-facility assessments in the following bullets. The common needs include:

- Control System Improvements
- Evaluation of Level Measurement Technology – Ultrasonic vs Radar Instruments
- Chemical Fill Station Level Indicators
- Evaluation of Valve Control Philosophy – Valve Network (PakScan) vs Hardwired
- Fire Alarm System and Gas Monitoring Minimization
- Open Channel Flowmeter Alternatives
- Process Monitoring Cameras
- Additional Local Control
- Generator Run Status Signals to Historian
- Study for Disabled Motor Moisture Detection Capabilities

SCADA Data Review: In order to better understand the condition of level and flow signals generated from the numerous level sensors and flow meters throughout the nine CSO facilities, Jacobs conducted a detailed SCADA Data Review. This evaluation obtained and reviewed SCADA data from a recent 6-month period (August 2019 to February 2020). This evaluation was used to help determine whether some of the redundant instrumentation could be minimized (for example, see I&C sections of Baby Creek and Conner Creek). Furthermore, this evaluation was used to populate information in the CS-299 Condition Assessment related to whether the instrument “Performed Its Intended Function.”

5.4.2 Control System Improvements

Because the CSO facilities were constructed at various times over the last 25 years, the control systems vary. Table 5-13 provides a summary of the existing control systems at each facility. The table also provides the proposed and recommended upgrades for the control systems at all the facilities to standardize the systems and make operating these facilities more similar from one facility to another.

Table 5-13. Existing and Proposed SCADA Control Systems at Each CSO Facility

Facility	Existing Control System (Version)	Proposed and Recommended Upgrades
Baby Creek	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7 Replace local control panel at Sampling Building and provide control from Sample Building
Belle Isle	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7 Add root switch for network redundancy
Conner Creek	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7
Hubbell Southfield	Rockwell ControlLogix PLC's with Factory Talk software	Replace entire control system (proposed project under CS-299)
Leib	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project
Oakwood	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7
Puritan-Fenkell	Rockwell PLC 5 with RSView software	Replace entire control system (proposed project under CS-299)
Seven Mile	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project
St. Aubin	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project

Note:

PLC = programmable logic controller

During CS-299 Facilities Assessment meetings, GLWA personnel requested that the control systems and screen graphics be standardized across facilities so that staff could more easily understand the controls and operation from one facility to another. GLWA SCADA Governance Standards require that all CSO facilities use Ovation workstations with new high-performance graphics. Version 3.7 of Ovation should be used. The recommendations in the following paragraphs address these issues.

"Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" is a project that is intended to replace the control systems at the three facilities mentioned. The request for proposals (RFP) for this design/build project should be issued within the next few months (as of August 2020). A Jacobs team member was involved in the development of the RFP documents for this project and was able to convey the GLWA CSO team's desire for standardization. For this project, the workstations with high-performance graphics will be Ovation. The RFP will allow for either Ovation or Rockwell control system to be bid, so that it can be more competitively priced.

Replace Entire Control System: Hubbell Southfield and Puritan-Fenkell control systems and workstations are Allen Bradley programmable logic controller (PLC)-based systems that are obsolete and do not meet GLWA's Governance Standards. These systems should be replaced. The Facility assessments for Hubbell Southfield and Puritan-Fenkell provide project descriptions and recommendations for the replacement project.

Ovation Control System Upgrade: The Ovation Control System at the existing four facilities (Baby Creek, Belle Isle, Conner Creek and Oakwood) will provide GLWA reliable operation for many years. With the advances in technology and new operating systems, it is logical to upgrade the Ovation system to take

advantage of new capabilities to improve performance and ensure reliability of the system. For the Ovation system to have high-performance graphics and elements, the system needs to be upgraded to version O.V.3.7. Once upgraded, the system will be able to utilize the latest graphic elements in Ovation that GLWA is currently pursuing.

The potential control system upgrades are listed in the following paragraphs (and are subject to change during design phase):

- High-Performance Graphics: Provide use of new screen graphic macros to maximize the experience with high-performance graphics.
- Remote Node Interface: Ability to expand the system with Ethernet based remote nodes that have the capability to handle smart modules such as ELC, Profibus, or Fieldbus in remote locations.
- Machinery Health monitor: Vibration sensors to collect raw data and software to analyze and predict failures.
- Updated OCR1100 Controller: Updates to controller software and interfaces to handle high speed applications along with an enhanced set of control algorithms.
- Windows Server 2016 and Windows 10: Operating system obsolescence will no longer be an issue along with security patch availability.
- Trusted Domain capabilities: Allow all GLWA system credentials to be available for authentication at all sites and systems.
- HART capabilities enhancements: Allows the system to communicate to 254 HART variables via the wireless HART device.
- Enhance system viewer/analyzer: Provide the ability to troubleshoot by including the option to filter by message type or time. Additionally, the level of criticality can be selected to ensure only the most important items are viewed.
- Gigabit network communication capability and up to 500,000 tags.
- Upgrade Fiber Network to OM3 fiber to support greater distances with gigabit capabilities.

5.4.3 Evaluation of Level Measurement Technology – Ultrasonic vs Radar Instruments

Many different technologies exist for level measurement. The predominant methods for measuring liquid level in the water industry are through ultrasonic level measurement and radar level measurement. Both methods rely on transmitting a wave and tracking the time it takes to receive an echo from the reflected wave. With ultrasonic, the wave is acoustical and with radar, the wave is electromagnetic. When the CSO Facilities were originally designed and constructed, ultrasonic was the dominant technology for level measurement. Radar level instruments were just beginning to come to market and were much more expensive and not as accurate as ultrasonic level instruments. It was common to have the ultrasonic technology be the primary level instrument and the radar technology to be the secondary level instrument.

Today, the opposite is true. Radar level measurement has improved, and for many applications is superior to ultrasonic level measurement. The frequency of the electromagnetic wave has increased with each new version introduced which provides for a narrower beam spread with less chances of error introduced from waves reflecting off of different surfaces. In addition, the higher frequency allows for more accurate level measurement in water containing small particles of debris and/or foam. Radar level instruments are a 2-wire, loop powered device and do not require a separate 120-volt (V) power feed, unlike ultrasonic level instruments. This saves on installation costs by eliminating additional conduit and wire.

In the future, Jacobs recommends that new level instruments would be radar as the primary level and ultrasonic as the secondary (if secondary is required). Since the radar instruments are loop powered, an additional source of 120V power and the associated conduit and wire is not required. The radar level instruments tend to have a lower unit cost and slightly more accurate and reliable than ultrasonic. For existing installations where ultrasonic level instruments are successfully being used and it is time for replacement, the recommendation would be to re-install an ultrasonic level instrument, since 120V power and the associated conduit and wire is already present, and the mounting location is already set for ultrasonic.

5.4.4 Evaluation of Open Channel Flowmeter Technologies

At the CSO Facilities, Accusonic open channel flowmeters are commonly used to measure flow. The meters are expensive to purchase, expensive to maintain, and frequently have issues accurately measuring flow.

Two alternatives are available for flow measurement besides the Accusonic units. The alternatives are described in the following paragraphs.

Alternative 1 - Laser-Doppler Velocity Flow Measurement: The non-contact laser-doppler velocity sensor measures flow by using a combination of a laser beam to measure velocity in a pipe or channel and an ultrasonic level sensor to measure the level of the liquid in the pipe or channel. Once the level of the channel is known, the laser beam is focused on a specific point and the frequency shift is measured on the returned light. The flow is then calculated from the cross-sectional area of the pipe or channel (accounting for level) multiplied by the velocity. An example of this type of flowmeter is the TieNet 360 Laser Flowmeter.

Advantages:

- Non-contact with the liquid in the pipe or channel. This provides for better accuracy by not disturbing the flow of liquid and will also remain cleaner by not being exposed to debris in the liquid.
- Ability to be submerged and still measure flow (requires optional surcharge sensors).
- Less expensive than Accusonic.

Disadvantages:

- The 45-degree angle of the laser beam requires special mounting considerations. This involves using an opening in the pipe or channel to accommodate the geometry of the 45-degree beam along with the downward facing ultrasonic level sensor. An alternative is to use a remote mounted ultrasonic meter and use one opening where the 45-degree beam enters the channel, or use two smaller openings; one above the ultrasonic meter on the main unit, and one for the 45 degree beam.
- Generally, requires a larger structure to account for the special mounting.
- Distance limitations between the flow sensor and flow transmitter. The manufacturer supplied cable is limited to a maximum 150 ft. In order to increase this distance, an additional extender module is required, and larger cables are required to counteract the voltage drop in the cable.

Alternative 2 - Radar Velocity Flow Measurement: Similar to the laser-doppler velocity flowmeter, the non-contact radar velocity sensor measures flow by using a combination of a radar beam to measure velocity and an ultrasonic level sensor to measure the level of the liquid in the pipe or channel. The radar is pointed to the center of the flow stream to measure surface velocity by calculating the frequency shift of the returned radar beam (doppler effect). The flow is then calculated from the cross-sectional area of the pipe or channel (accounting for level) multiplied by the velocity. An example of this type of flowmeter is the Hach Flo-Dar.

Advantages:

- Non-contact with the liquid in the pipe or channel. This provides for better accuracy by not disturbing the flow of liquid and will also remain cleaner by not being exposed to debris in the liquid.
- Ability to be submerged and still measure flow.
- Less expensive than Accusonic.

Disadvantages:

- The mounting design of the radar velocity flow measurement is meant to be installed on a bracket located in the bottom of a manhole directly above the channel or pipe opening. Access to the meter would be limited unless a large manhole was used above the pipe or channel.
- Would require a larger structure similar to the laser-doppler velocity meter to provide access to the meter.

It is recognized that GLWA has recently replaced all of the Accusonic influent flow meters at the large CSO facilities (i.e., Baby Creek, Conner Creek, Hubbell Southfield, Leib and St. Aubin). These facilities have a contract for bi-annual maintenance of these meters. Given this current situation, it is recommended that the Accusonics continue to be used. As these units age and as technology continues to advance, alternative flow meters could be evaluated in the future.

Jacobs recommends one location (Conner Dewatering) where a new Laser-Doppler Velocity Flow Meter should be installed. This is further discussed in Section 8.2.7.3.

5.4.5 Chemical Fill Station Level Indicators

Level sensor indicators are necessary at the fill stations of all chemical storage tanks. This allows contractors to monitor tank level from outside the building while delivering sodium hypochlorite. GLWA staff are replacing level sensor indicators at St. Aubin and Leib, but replacement is required at Belle Isle. All other facilities require installation of new level sensor indicators.

For the CSO Facilities which require new level indication, it is recommended for the design to include a NEMA 4X enclosure, digital process display with large, red characters which are easy to read, panel heater, and an alarm horn or strobe to indicate when the tank is approaching a high level. The 4-20 milliamperes (mA) level signal used for the process display indication should be part of the 4-20 mA instrument loop between the level sensor and PLC analog input and should indicate how full the tank is and how close it is to overflow. The alarm horn or strobe should be powered through a relay from the process display and based on an adjustable setpoint through the process display setup. A reasonable level should be chosen for the setpoint, which might be 12 inches (in.) to 24 in. below the top level of the tank. If a horn is used for the level indication panel, a "test" and "alarm silence" pushbutton should be incorporated to the front of the panel.

5.4.6 Evaluation of Valve Control Philosophy – Valve Network (PakScan) vs Hardwired

The PakScan valve network is a proprietary networking system for use with Rotork electric actuators. The valve network utilizes a serial communication protocol to carry all valve actuator status and control signals over a two-wire system. Valve networks have advantages and disadvantages. For PakScan, the network can accommodate hundreds of individual valve actuators spanning over many miles apart. The valve network is capable of transmitting a multitude of status and control signals nearly instantaneously across the entire network. Some of the disadvantages of the PakScan valve network include losing status and control

of all valve actuators in the event of a cable malfunction and associated networking difficulties during power cycles (such as valve actuators losing IP addresses while the network is coming back online).

For the CSO Facilities which utilize PakScan valve networks (i.e., Baby Creek, Conner Creek, Puritan-Fenkell, and Seven Mile), Jacobs considered an alternative of maintaining the existing valve network for status monitoring, but converting to hardwired control for critical status and control functions. The addition of hardwired control would involve the addition of conduit and wire between the valve actuators and the nearest PLC panel. Any discrete status and control would be through No. 14 AWG wire. Additional I/O would likely be required in the PLC panels. If the PLC panel would not have space or capacity for additional valve actuator I/O, remote I/O panels would be required to collect the status and control signals and be tied into the local PLC panel. The major benefit of this alternative is that, in the event the valve network experiences issues or outages, the hardwired control would still remain as a backup to keep the CSO Facility in operation.

Construction costs (without Contractor overhead and profit or Engineering design) for this concept for all the actuators at the four CSO facilities was found to be fairly expensive, as follows:

- Baby Creek (60 actuators): \$204,000
- Conner Creek (107 actuators): \$355,000
- Puritan Fenkell (19 actuators): 68,000
- Seven Mile (15 actuators): 54,000

Based on this information and discussion with GLWA, the cost/benefit of this alternative was not considered to be favorable. The exception is the 16 effluent relief gates at Conner Creek, which could cause major flooding damage in the collection system if they do not open as programmed during a large storm event. As such, this alternative is not considered further, except for the Conner Creek effluent relief gates.

5.4.7 Fire Alarm System and Gas Monitoring Minimization

Minimization of Fire Alarm Systems: GLWA requested that Jacobs investigate potential locations where fire alarm and sprinkler systems could be eliminated. As part of this investigation, Jacobs recognizes that each facility was designed by professionals to meet current fire and safety requirements and codes. Furthermore, the designs and final installations were reviewed and approved by the City Fire Marshall. For these reasons, we do not recommend that the current fire safety systems be modified, unless further evaluated under a separate study.

Removal of Gas Monitors from Various Basins: GLWA also requested that Jacobs investigate the potential removal of gas monitors in the basins for Belle Isle and Oakwood CSO Facilities. When originally installed, the gas monitoring in the basin was the primary method to determine if dangerous gas levels were present and if it was safe for personnel to enter. Since then, the standard operating procedures have been updated to make personal meters worn by personnel the primary means for checking for dangerous gas levels. Per NFPA 820 Standard for Fire Protection in Wastewater Treatment and Collection Facilities, Table 4.2.2, Row 32, Fire Protection measure, which include combustible gas detection, is not required in wastewater holding basins.

For the gas monitoring equipment in the basins at Belle Isle and Oakwood, the recommendation is to remove the existing gas monitors to avoid the effort required to maintain the sensors. This recommendation is also based on the fact that entry into basin (confined space) requires individuals to have their own gas monitor, along with fans on. The existing conduit and wire should remain as spare and left for future use.

Gas monitors in the Headworks should remain for the same reasons as the fire alarm systems mentioned above.

5.4.8 Process Monitoring Cameras

During Facilities Assessment meetings with O&M staff, GLWA requested that Jacobs evaluate locations in which additional cameras would be beneficial to monitoring operations. With GLWA input, the locations of existing cameras and the number of new cameras required at the CSO facilities were identified. A summary of desired camera locations is presented in Table 5-14. For this report, the costs associated with cameras are included in the individual facility I&C Improvements project.

Table 5-14. Process Monitoring Camera Needs at Each CSO Facility

Facility	Location	Number of new cameras required	Notes
Baby Creek	Headworks	4	One camera for a group of four screens
	Influent Area	1	Focused on area upstream of the weir wall
	Chemical Room	2	PTZ ^a
Belle Isle	Headworks	1	Existing camera in the headworks needs updating
	Chemical Room	1	
Conner Creek	Headworks	3	
	Chemical Room	2	One camera inside and one camera outside. PTZ
	Outfall	0	Camera will be installed as part of ongoing security project
Hubbell-Southfield	Headworks	3	PTZ
	Chemical Room	1	PTZ
	Outfall	1	
Leib	Headworks	0	There is an existing camera in the headworks area
	Chemical Room	1	PTZ
Oakwood	Headworks	3	PTZ
	Chemical Room	2	PTZ
	Pump Room	2	PTZ
Puritan-Fenkell	Headworks	2	
	Chemical Room	1	PTZ
	Outfall	1	PTZ
Seven Mile	Headworks	No	
	Chemical Room	No	
St. Aubin	Headworks	1	Existing camera in headworks area needs updating
	Chemical Room	1	PTZ

^a PTZ is a point, tilt, zoom camera

5.4.9 Install Local Control Near Process Equipment

GLWA staff requested local control capability for some equipment to improve operability, for example submersible dewatering pumps and mixers at some locations. For areas where local control would provide a benefit, a standard approach would be taken for all CSO Facilities.

- In classified areas, local control stations should be added next to the equipment in NEMA 7 explosion-proof enclosures. Start and stop pushbuttons, local-off-remote selector switches and push-to-test indicating lights would be specified for the local control station. For applications involving VFDs, speed indication and speed control potentiometers should be included on the local control station.
- For non-classified areas, local control stations should be added next to the equipment in NEMA 4X stainless steel enclosures. Start and stop pushbuttons, local-off-remote selector switches and push-to-test indicating lights would be specified for the local control station. For applications involving VFDs, speed indication and speed control potentiometers should be included on the local control station.

The local control stations would require new conduit and wire back to the motor starters, typically located within MCC. The internal control circuits would need to be modified and updated to include the additional local control stations.

For typical applications, the multi-conductor exposed cables would route up through the wet-well to either quick-disconnect devices, or permanent terminal boxes. Seal-off fittings would be incorporated where required by code between the local control stations and terminal boxes/quick-disconnect devices.

The Instrumentation and Control sections of each facility provide the locations where remote control of equipment was recommended by O&M staff. These include:

- Baby Creek screens (see Section 6.2.7.3)
- Hubbell Southfield dewatering pumps (see Section 9.2.7.3)
- Leib fine screens (see Section 8.2.1.3)
- St. Aubin dewatering pumps (see Section 14.2.7.3)

5.4.10 Automatic Transfer Switch and Generators Controls Upgrade

Seven CSO facilities have standby generators (i.e., Belle Isle, Conner Creek, Hubbell-Southfield, Leib, Puritan-Fenkell, Seven Mile, and St. Aubin). The reliability of these generators and automatic transfer switches (ATS) has declined over recent years. During utility power outages when the standby generators are necessary, either the generators do not start automatically, or the ATSs do not transfer. In addition, the generator control panels and the ATSs do not report status or alarm signals to the operators through the SCADA Ovation control system.

The “Automatic Transfer Switch and Generators Controls Upgrade” project is an ongoing project that will address these issues. Under this project, the CSO facilities with standby generator systems will be upgraded to have a standardized, dedicated automatic transfer control system. In addition, the project will include the following:

- 1) The PLCs or other controller styles will be replaced with modern, standardized, microprocessor-based automatic transfer controllers.
- 2) The front panel of ATS panels not being fully replaced will be reconfigured to be standardized across all CSO facilities. A remote human-machine interface (HMI) screen dedicated for the automatic transfer system will be provided.
- 3) Local generator panels will be evaluated for compatibility and reliability.

- 4) Ovation displays will be standardized and useful inputs (alarms, configuration, status) will be included.

5.4.11 Study for Disabled Motor Moisture Detection Capabilities

Throughout many of the CSO Facilities, motor moisture detection used for mixers and dewatering pumps has been disabled using wire jumpers to bypass the shutdown control circuits. While this practice could be considered acceptable during emergency situations, the problem comes from not removing the wire jumpers after the CSO event and correcting the underlying moisture problem in the motors. As time goes on, these jumpers are forgotten about, as well as additional, new jumpers being added for other motors. Jacobs recommends a study of all facilities to identify the location of all existing jumpers used on the motor moisture detection circuits and then develop a plan to remove the jumpers and correct the motor moisture detection issues.

5.5 Structural

A Structural Rehabilitation Needs Assessment, dated August 2018, was conducted by NTH Consultants for all nine CSO facilities under a separate project. In this assessment, NTH assessed structural defects in aboveground buildings and belowground structures. The purpose of this assessment was to provide bridging documents for an upcoming CSO Structural Rehabilitation design/build project, which is scheduled to begin in early 2021. As such, it is not considered a complete list of all the structural defects. The selected design-build firm will be generating an updated, more complete list of defects at the start of their project. Because the structural assessment will be completed soon, structural rehabilitation capital costs are not presented in this report.

5.6 Building Roofs

A Roof Asset Condition Assessment, dated July 19, 2018, was conducted by NTH Consultants under a separate project for eight of the nine CSO facilities. (Puritan-Fenkell was not included in the assessment because a planned roof replacement was out for bid at the time of the inspections). The purpose of this assessment was "to visually examine the facility roofs, determine needs and priorities, and recommend optimal remedial roofing work strategies that will ensure a maximum return on investment and optimize the use of facility maintenance funds." The assessment included the size (in square ft) of each roof, roof membrane type or composition, slope, year installed, roofing contractor, roof system manufacturer, and roof condition/service projection. Each roof was rated good, fair, or poor. The results of the 2018 roof assessment are included in Volume 6 – Appendices, Appendix H.

The results of the roof condition assessments were used by the CS-299 team to populate the condition of the roofs for each facility in CS-299 Condition Assessment. In some cases, the roof has been replaced since the assessment; these scores have been adjusted accordingly.

5.7 Safety

5.7.1 CSO Facility Safety Inspection

Under CS-299, Jacobs conducted a safety inspection of all the CSO facilities in January 2020. The purpose of the safety inspection was to identify safety-related issues. The report identified whether the issue should be addressed through a future capital improvement or non-capital projects. The findings of the safety inspections were presented in the CSO Facility Safety Inspection Report, dated March 30, 2020, included in Volume 6 – Appendices, Appendix E.

5.7.2 Safety-Related Capital Improvement Projects for Each Facility

Safety-related capital improvement projects at the CSO facilities generally fall into one of the following categories:

- 1) Fall Protection Improvements – the approach for fall protection and recommended improvements are discussed in Section 5.7.3.
- 2) Eyewash and Emergency Shower Improvements – to be included in each facility Safety cost estimate.
- 3) Exit Sign Improvements – see discussion in the following paragraphs for proposed project to address these issues.
- 4) Conner Creek Conveyor Improvement – See Conner Creek Screening section (Section 8.2.1.2) for project that is addressing this issue.

Emergency Lighting: Emergency lighting issues identified in the Safety Inspection Report are not included in the capital improvement projects since it is understood by Jacobs that these issues will be addressed in the recently completed LED Lighting Project.

Exit Sign Improvement Project: Illuminated exit signs and emergency lighting were not functioning or not present at many locations. Emergency lighting is being addressed in the ongoing LED Lighting Project. The emergency lighting project may provide illumination of exits in various locations, thus affecting the exit locations that need to be addressed in this project. Also, some of the exit sign bulbs may simply need to be replaced. As such, it is recommended that Exit Sign Improvement projects include an exit route survey at each facility meeting NFPA 101 (Life Safety Code) requirements, Michigan Building Code requirements (2015 ver.) and MIOSHA regulations. This task is being addressed in a separate project under Task Order Engineering Services (TOES). As such, capital costs are not included in this section.

Safety-related capital improvement projects are recommended for each individual facility. The detailed cost estimates in Volume 6 – Appendices, Appendix C provide the safety-related items included for each facility.

5.7.3 Fall Protection Improvements

Using the information presented in the Safety Inspection Report, preliminary recommendations for improvements at each hatch opening were generated. These are included in Table E-1 in Volume 6 – Appendices, Appendix E. The purpose of this table is to provide a basis for the project cost associated with fall protection. Design of some of the safety recommendations will be required, and, therefore, the costs may change in the future.

The following general approach was used for the preliminary recommendation at each hatch opening:

- 1) In general, permanent railings are preferred since they provide the most reliable protection. This includes most roof access hatch locations. It also includes other locations where there are no traffic or access issues. However, permanent railing are not practical at all locations due to the need to maintain traffic or access. These locations need to consider some other form of fall protection.
- 2) For hatch openings for equipment removal, where permanent railings are not practical, GLWA O&M staff has requested that nets be provided.
 - For equipment openings with double leaves where each side is at least 3.5 ft high (42-in.) when opened, chains could be added to the existing leaves at the top and middle. This would provide fall protection for these hatch openings.

- For equipment openings where the hatch leaves are not 3.5 ft high, Jacobs recommends temporary/portable railings be provided to protect other staff at locations where the hatch could be left open and the net pulled back for equipment removal for an extended period of time. The temporary railings can be either custom-made railings from a local fabricator that slide into cored holes in the floor (for inside locations only), or they could be standard portable railings purchased from a handrail manufacturer.
 - If temporary railings are not acceptable for these equipment openings, Jacobs recommends that D-rings be used in conjunction with staff in a safety harness to provide fall protection for the worker while removing/installing equipment.
- 3) For hatch locations for ladder access into confined spaces (i.e., basins or vaults), a portable davit in conjunction with a worker safety harness is recommended, as the davit provides both fall protection and aids in personnel rescue, if needed. A ladder ratchet system could also be used for fall protection; however, it is not as effective for retrieval.
 - 4) All ladders should have retractable safety posts at the top of the ladder for improved safety when entering or exiting the opening.
 - 5) At Conner Creek at the time of the Jacobs safety walk-through, it was noted that many small (2 ft by 2 ft) hatches for lighting in the basin were left open. Netting is recommended at these locations as a permanent safety measure, as well as D-rings to provide fall protection during light bulb replacement.

In addition to fall protection, other modifications or enhancements are needed at some hatches to address various deficiencies. These issues are included in the “Additional Items” column of the spreadsheet and should be more thoroughly evaluated during the detailed design for modifications to the hatches at each facility. The most notable modifications include:

- 1) Replacing the 16 plates over the mixers at Leib with hatches.
- 2) Re-orienting the basin access hatches, as necessary, to make closing the hatch safer. See Figure 5-9 for an example at Belle Isle basin where staff must reach across opening to actuate the red handle to close the hatch.

Figure 5-9. Example of Need for Re-orienting the Basin Access Hatches

- 3) Replacement of the cylinders to aid hatch opening and closing should be evaluated at the time of replacement of all hatches.
- 4) Installation of a ladder safety system or personal fall arrest system for existing fixed ladders over 24 ft in height by November 18, 2036, for any section of the fixed ladder/cage/well that is replaced, or for any new fixed ladder exceeding 24 ft in height, per revised OSHA standard 1910.28(b)(9). Existing cages on ladders will require replacement with an alternate fall arrest system or ladder safety system to meet the revised standards.
- 5) A preliminary list of ladders with cages are presented in Table E-1 in Volume 6 – Appendices, Appendix E. It is recommended that the replacement of existing ladder cages be included in future capital improvement projects between now and 2036, and as such, cost estimates are not included in this assessment.

Other fall and trip hazards were present at several locations. These are listed in Table E-1 in Volume 6 – Appendices, Appendix E. Many of these hazards can be addressed with the addition of fall protection features such as temporary railings and are generally included in the cost estimates for each facility. Note, that since the safety inspection report was issued in March 2020, Jacobs was notified by GLWA that swing gates are current practice – chains are not acceptable fall protection. The project costs for fall protection for each individual facility are presented in the facility-by-facility Safety sections.

5.8 Maintenance Work Order Review

The CS-299 CSO Facilities Assessment scope of work required Jacobs to review historical maintenance work orders (WOs) as one component of the Facilities Assessment. The purpose of this review was to determine whether useful information can be obtained from the WOs to aid in the identification of future improvements to the assets, specifically related to capital improvements. For example, if there is evidence within an asset's work order history that pointed to recurring problems, this evaluation could potentially identify that asset to be a candidate for capital improvement to address the issue.

The WO review, included in Volume 6 – Appendices, Appendix F, presents the findings from the review of historical maintenance work orders from 2013-2018. As indicated in the summary, this review did not provide significant information that is useful to determine the need for capital improvements to assets. While there are several WOs that address asset repairs, these generally appear to be normal wear items and do not indicate an installation or performance concern. Information from this review was used to compare reliability of chemical induction mixers.

6. Baby Creek CSO Control Facility

6.1 Facility Description and Future Capacity Considerations

6.1.1 General Facility Description

The Baby Creek CSO facility is a SDF with 3 million gallons (MG) of storage, and a treatment capacity of 5,100 cfs. It was constructed in 2006. The facility has a nearly 1-mile long effluent conduit used for disinfection contact time before discharge into the Rouge River. The facility consists of one main building with a large Headworks, Chemical Room, utility support (two Electrical Rooms and a Mechanical Room), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building near the end of the effluent conduit and outfall access at the Rouge River (Miller Road Gates).

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

6.1.2 Future Capacity Considerations

Based on a review of the WWMP and discussions with GLWA, there were no future increased capacity considerations identified at this facility.

The high water levels in the Great Lakes and Lower Rouge River, however, have created the need for using the bypass gates during peak flows of larger wet weather events, before the design-rated capacity of the screens is reached. This issue is further discussed in the Screening and I&C in the following sections.

6.2 Facility Assessment

6.2.1 Screening

6.2.1.1 Description of Existing System

The Baby Creek CSO facility has 16 perforated panel screens that were installed in 2006. The influent weir to the first four screens is set one foot lower than the remaining 12 screens so that only the first four screens are used during smaller storm events and lower flow periods. This means flows are preferentially sent through the Elmer Ternes barrel of the Outfall.

Soon after startup of the facility, the screens significantly blinded during a large wet weather event due to heavy leaf load in the influent wastewater. Water backed up in the sewer system causing flooding issues in the community upstream of the facility. Modifications were made to the screens to address this issue including running the units at high speed (VFDs were provided for the original system and are still installed, but now they are only run at high speed) and eliminating the start/stop control of the screens based on differential level. Currently, the screens are operated when the water level spills over the influent weir wall. Furthermore, a bypass channel was constructed around the screening and disinfection portion of the facility. This bypass channel can be and has been used when there was reported blinding of the screens during high flow events or when levels in the influent sewer are high.

The operators report that they have used the bypass about four to five times during the past two years, which is more frequent than in the past due to the unprecedentedly higher water levels in the Great Lakes over the past year. When the bypass gates are opened, the bypassed flow does not receive screening or

disinfection, making this a significant issue. Bypasses are considered a violation of the NPDES permit by EGLE.

Screenings from the screens discharge into a sluice channel. The screens are equipped with a rotating brush and spray water to aid in the removal of the screenings from the screen. Flushing pumps pump raw wastewater to the sluice channel to convey the screenings to the Toward Treatment Sewer.

Table 6-1 provides an overview of the existing screening system at Baby Creek CSO facility.

Table 6-1. Overview of Existing Screening System at Baby Creek CSO facility

Parameter	Value
Treatment Capacity (cfs)	5,100
No. of Screens	16
Manufacturer	US Filter – John Meunier (now Veolia)
Screen Type	Perforated Panel Screen
Opening Size	6-mm perforation
Depth or Length / Width	26 ft 6 in / 10 ft 0 in
Screen Cleaning	Brush and high-pressure spray
Screening Removal	Conveyed through sluice trough to Toward Treatment Sewer and to WRRF

6.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Improve existing screens for blinding and reliability. Note that the evaluation of screen blinding is presented in the next section. It was determined that blinding was not a major issue and does not require a capital improvement. During the investigation, however, a potential improvement to the screen brushes was proposed and is evaluated under Replace Existing Screen Brushes (Project BC-SCR-1).
- Evaluate maintenance access to Screen 5. Unlike the other 15 screens, Screen 5 is unable to tilt up to Headworks floor due to interference by a large tipping bucket. Jacobs contacted Veolia to obtain input on maintenance procedures for this screen, given this constraint. They indicate that this screen needs to be only slightly pivoted to make the lateral doors near the bottom of the screen accessible and work on the bottom elements (i.e., sprockets, stub shafts, bushing, etc.) needs to be performed in the channel. Based on this input, this issue is not evaluated further.

6.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with a recommended alternative.

Improve existing screens for blinding and reliability. Operations staff reported that the screens blind about twice per year, once in the spring and once in the fall. If blinding is occurring, it may be increasing upstream water levels such that bypassing of the screens is required, which is a permit violation.

An assessment of screen blinding was conducted under CS-299. SCADA data was collected for seven storms between July 2017 through January 2020 for water levels upstream and downstream of the

screens. This information was used to evaluate the level differential (i.e., upstream level minus downstream level) through the screen during the entire storm event. If the screens blind, the level differential through the screen will increase significantly compared to the rest of the event.

Table 6-2 provides a summary of the storms and the level differentials.

Table 6-2. Peak Total Influent Flow and Screen Level Differential During Storm Events

Storm Date	Peak Total Influent Flow (cfs)	Level Differential Throughout Storm (inches)
11/18/17	952	5 – 8
4/15/18	614	5 – 8
5/12/18	878	5 – 9
10/2/18	405	5 – 8
7/7/19	872	19 – 31
10/27/19	1149	6 – 7
1/11/20	1444	6

Figure 6-1 and Figure 6-2 show water levels upstream and downstream of the screens as well as the river elevation and flow for the two storm events in October 2019 and January 2020, respectively. The upstream water level is shown in light and dark green and the downstream water level is shown in red and magenta. The screen differential levels in Figure 6-1 and Figure 6-2 are representative of all of the storms except for the July 7, 2019, storm as discussed below.

Figure 6-1. Screen Differential Level during October 27, 2019 Storm

Figure 6-2. Screen Differential Level during January 11, 2020 Storm

Below are findings from analyzing the level differential data for all of the events.

- All events show a relatively constant differential across the screen during the entire storm event, regardless of flow rate throughout the storm. It should be noted that the differential through the screens should be greater during high flows and smaller during lower flows. The sensors should be checked for calibration as an annual recurring preventative maintenance (PM) activity.
- The differential varies from storm event to storm event; however, the value is nearly constant through an individual storm event. For example, differential was 6 in. for the entire January 11, 2020 storm and 6 to 7 in. for the October 27, 2019 storm. One storm (July 7, 2019), however, had differential of 19-31 in. throughout the storm event. This range was due to the fact that the influent level sensors had a 12- in. difference between the two readings for the entire event, which is not considered accurate.
- There are spikes in the level at the beginning of two events (May 11, 2018 [not shown] and January 11, 2020). These could be considered blinding caused by a first flush since the level rapidly increases, then decreases. In fact, for the January 11, 2020 storm, the bypass gates had to be opened at the beginning of the event. However, the downstream level shows the same spike. This indicates that blinding is not the cause of the spike in level. Rather, it is likely caused by the rapid increase in flow to the facility.
- The January 11, 2020 demonstrates that the river level affects the upstream levels. As noted on the figure (Figure 6-2) on January 12, 2020, an increase in the river level increases the downstream and the upstream screen levels.

Based on the constant level differential across the screens during large storm events, the screens do not show evidence of blinding. This issue was reviewed with GLWA on April 16, 2020. It was concluded that blinding was not occurring. As such, capital improvements intended to specifically reduce screen blinding will not be beneficial.

Replace Existing Screen Brushes (Project BC-SCR-1). During the investigation of the blinding issue and previous Veolia site visits, Veolia indicated that there is a new type of brush mechanism for the screens. The current mechanism is stationary, and a newer, current version of the mechanism is self-adjusting. All new screens of this type from Veolia have self-adjusting brush mechanisms. Reportedly, the self-adjusting brush maintains better contact with the screen panels at a constant pressure as the panels pass by the brush improving removal of screenings and extending brush life. The existing screen could be retrofitted with the new mechanism to potentially improve screenings removal and extend the life of the brush.

Due to the lack of supporting data related to the benefits of the newer brushes, GLWA could consider piloting the self-adjusting brush mechanism on two of the more frequently used screens (i.e., Screens 1 to 4) to compare its performance and the impact on brush life. Based on these results, GLWA would be able to determine whether to replace the brush mechanisms on the remaining screens. As such, there are two alternatives with this option:

- 1) **Alternative 1: Replace Existing Brushes In-Kind.** Replace with stationary brushes for two screens.
- 2) **Alternative 2: Pilot Self-Adjusting Brushes.** Replace with self-adjusting brushes for two screens.

The alternative evaluation is presented in Table 6-3. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 is based on brush costs from Veolia from a recent brush replacement order in 2019. Cost is for two brushes, installed by GLWA maintenance.

- The capital cost for Alternative 2 are included in Volume 6 – Appendices, Appendix C, under this project title, and are based on a quote for two brushes. Installation of the brushes is assumed to be performed by a contractor.

This analysis does not account for a potentially longer life of the brush, which would be determined through the pilot evaluation. Review of the NPV/Benefit costs, however, shows that the self-adjusting brushes would need a longevity of approximately four times longer than the existing brushes to be considered the Best Value Alternative. It is not anticipated that the self-adjusting brushes would have a longevity long enough to be considered the Best Value Alternative. As such, **Alternative 1: Replace Existing Brushes In-Kind is the recommended alternative.** Because this should be considered a wear item, it is not included in the capital improvement projects; rather, brush replacement should be included in a Capital Outlay for these screens.

Table 6-3. Alternative Evaluation for Replace Existing Screen Brushes (Project BC-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Screen Brushes In-Kind	Health and Safety	3	2.40	\$ 36,000	\$ -	\$ 36,000	\$ 15,000	Best Value Alternative
	<i>Definition:</i>	Replace existing screen brushes in-kind when they have worn	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Shorter brush useful life due to higher wear rate. Not as effective at cleaning the screen.	Component Performance	2						
	<i>Comments:</i>	Brush costs from Veolia. Assumes GLWA labor for installation.	O&M Ease	2						
2	<i>Alt. Name:</i>	Pilot Self-Adjusting Brushes (Two Screen Pilot)	Health and Safety	3	3.00	\$ 173,000	\$ -	\$ 173,000	\$ 57,667	
	<i>Definition:</i>	Install higher performance self-adjusting brushes.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher cleaning performance. Longer life due to less wearing.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	Although new brushes may last longer than existing bushes, this evaluation assumes the new brushes have the same useful life.	O&M Ease	3						

6.2.2 Disinfection

6.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of four rubber-lined steel tanks, eight self-priming centrifugal pumps with VFD speed control, eight disinfectant rapid mix zones, and 32 induction mixers. There are 16 screens and the flow from each pair of screens is funneled into a disinfectant rapid mix zone. There are four induction mixers per disinfectant rapid mix zone consisting of two low level mixers and two high level mixers. The sodium hypochlorite pumps discharge to two headers, one smaller than the other, which run the length of the Headworks and each connect to the manifold feeding the four induction mixers at each rapid mix zone. Flow splitting between the four induction mixers is not metered and is dependent on functioning back pressure valves with equal upstream pressure settings.

Table 6-4 provides an overview of the existing disinfection system at Baby Creek CSO facility and the disinfection process flow diagram is included in Volume 6 – Appendices, Appendix G.

Table 6-4. Overview of Existing Disinfection System at Baby Creek CSO facility

Parameter	Value
Treatment Capacity (cfs)	5,100
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L as Cl ₂)	20
Disinfection Contact Time (min)	10
Storage Tanks	
Number	4
Volume of Each Tank (gal)	36,000
Type	Rubber-lined steel
Pumps	
Number	8 Total; 2 low-rate, 3 mid-rate, 3 high-rate
Capacity (gpm)	Low-rate: 0-50, Mid-rate: 0-150, High-rate: 0-400
Type	Centrifugal
Mixers	
Number / Type	32 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC15XPL/ 15 hp / Water Champ

6.2.2.2 Identified Needs and Issues

The needs and issues for Baby Creek were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Baby Creek chemical feed system has the following issues:
 - The pumps and pipe supports in the vicinity of the pumps are corroding as a result of exposure to sodium hypochlorite.
 - A glued polyvinyl chloride (PVC) joint fails at an approximate rate of one every three months in the Chemical Room.

- The pumps have traditional drives requiring seal water, are reaching the end of their useful life, and include self-priming accessories adding to their complexity and increasing their footprint.
- The chemical piping is complex and congested.
- The back pressure valves controlling the chemical feed split between the four induction mixers at each disinfectant rapid mix zone are suspected of not functioning properly.

These issues are addressed in Replace Chemical Feed System (Project BC-DIS-1) in the next section.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BC-DIS-2) in the following bullet.
- There are 32 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3).
- Inefficient mixer removal system – includes evaluation of monorail vs. gantry cranes with electric hoist and electric trolley to replace existing hand chain hoist. This issue is addressed in Improve Mixer Removal System (Project BC-SUPP-1) at the end of this facility section.
- Modify floor slope in Chemical Room to drain to sump – This issue is addressed in the Architectural section (Section 6.2.9.3).
- Reline chemical storage tanks – Based on an inspection in 2020, the tanks are in need of relining to provide extended life. The repair/replacement of the liner is an ongoing project, so it is not included in the capital improvement projects for CS-299. The SRP model was manually adjusted to recognize the improvement of this ongoing project.
- Related to the relining of the storage tanks, GLWA requested that Jacobs review the historical and expected chemical usage compared to tank storage capacity to determine whether to reline all four tanks or only two or three tanks. Sodium hypochlorite usage for the four largest storms from 2016 through early 2019 was evaluated. The volume used was based on tank levels rather than flow meters because of suspicious flow meter data. The analysis indicated that the maximum used as a percent of total tank volume was 49 percent. This would indicate that the minimum number of tanks to be relined would be two. Had a larger storm occurred than the period analyzed then more than two tanks would be required assuming all other things equal (i.e., assuming the same dose and hypochlorite strength). Using more conservative assumptions of a 15 mg/L average dose and an assumed 5 percent hypochlorite strength, a volume in excess of the total four tank volume would be required. At an assumed dose of 15 mg/L and 9 percent hypochlorite strength three tanks would be fully consumed. Given the possibilities of a larger storm, hypochlorite degradation down to 5 percent, or the need for a higher dose, it is recommended that all four tanks be relined to retain the original design capacity at Baby Creek.
- Sump pump replacement in Chemical Room – This is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.
- Chemical make-up water actuator replacement in Chemical Room – This is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.

6.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project BC-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, BC-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 6-5. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital costs for Alternative 2 and 3 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 was developed based on GLWA experience of two pump rebuilds per year at a cost of \$13,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 6-5 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 6-5. Alternative Evaluation for Replace Chemical Feed System (Project BC-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 1,657,301	\$ 26,000	\$ 2,205,631	\$ 1,058,703	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with feeding too much chemical. System is unique to Baby Creek.	Component Performance	1						
	<i>Comments:</i>	Capital costs include pump replacement at Year 10	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 3,325,000	\$ 44,550	\$ 4,264,543	\$ 1,184,595	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per disinfection channel. Utilize hose pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual switchover.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 1,237,000	\$ 4,000	\$ 1,321,359	\$ 367,044	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps connected to all disinfection channels. Utilize centrifugal pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily utilized.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each disinfection channel.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BC-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Operation in manual at Baby Creek is noted by operations as being extremely difficult. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time must also be considered. The exact location would be determined during design. Based on the evaluation of a few years of recent data, the average flow rate during storms at Baby Creek is about 108 cfs. This is a very small percent of the design storm and 15 minutes contact time at average flow will be only a short distance downstream of the dose point (approximately 500 ft). The sampling location needs to be upstream of storm sewer flows which would dilute the measurement. If there is an existing access point that meets the criteria, then this should be explored during design. However, the cost of a new manhole will be assumed to access the sampling pump.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 6-6. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be consistently met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 6-6. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project BC-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 201,000	\$ 4,860	\$ 303,496	\$ 87,970	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	O&M to maintain analyzers based on 3 hrs/month.	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3). Plant personnel reported that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. These issues are exacerbated by having 32 mixers at Baby Creek, which is the second-highest of the nine CSO facilities. A reduction in the number of mixers would reduce maintenance and the associated expenses proportionate to the reduction. It would also reduce the complexity of equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4). The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** CFD modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from four to two per channel) based on the fact that the latest model shows design flows are about half of the original design flows.
- 3) **Alternative 3. Install Vertical Shaft Mixers.** This alternative would replace the existing chemical induction mixers with new vertical shaft mixers. For Baby Creek, two mixers would be provided per channel.

The alternative evaluation is presented in Table 6-7. The sources of costs used in this evaluation are listed in the following bullet:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$18,000 per mixer.
- The capital cost for Alternative 3 (vertical shaft mixers) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 (vertical shaft mixers) are based on expected maintenance costs, including changing oil, greasing bearings, periodic rag removal from the shaft and servicing the steady bearing.

As shown in Table 6-7, Alternative 2 has a Total Benefit score about 0.4 higher than Alternative 1 because of the improved ease of maintaining fewer mixers. Alternative 3 has a Total Benefit score about 0.3 higher than Alternative 2 based on the anticipated improved performance of the vertical mixers and improved ease of maintenance, since the mechanical portion of above the water surface. **Alternative 2, however, has the lowest NPV/Benefit cost and therefore, is the recommended alternative.**

It should be noted that the cost of the reduced mixers is not a new capital cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection performance can be achieved, the vertical mixer alternative should be further explored, possibly through the pilot testing of this technology in one of the channels at Baby Creek or Conner Creek.

Table 6-7. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Induction Mixers In-Kind	Health and Safety	3	2.57	\$ 3,200,000	\$ 230,400	\$ 8,059,052	\$ 3,139,890	
	<i>Definition:</i>	Replace existing mixers as required.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, lots of redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Expensive and impacts operations and maintenance. Equipment installed in channels. Possible ragging issues.	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period.	O&M Ease	1						
2	<i>Alt. Name:</i>	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	Health and Safety	3	3.00	\$ 1,650,000	\$ 115,200	\$ 4,079,526	\$ 1,359,842	Best Value Alternative
	<i>Definition:</i>	Perform CFD modeling to simulate performance with fewer mixers (assumed 50% of existing).	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less expensive and less impacts to operations and maintenance. Equipment installed in channels. Possible ragging issues.	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period & CFD Modeling of \$50,000.	O&M Ease	3						
3	<i>Alt. Name:</i>	Install Vertical Shaft Mixers	Health and Safety	3	3.32	\$ 7,033,000	\$ 56,000	\$ 8,214,020	\$ 2,476,589	
	<i>Definition:</i>	Replace existing mixers with vertical shaft mixers.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less equipment to operate and maintain. Overall less install horsepower. Equipment is above the basin and accessible in a non-confined space environment. Maintains redundancy requirements.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Bearing in bottom of channel. Possible ragging issues.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.3 Odor Control

6.2.3.1 Description of Existing System

The Baby Creek odor control system is a Calgon Carbon PHOENIX automatic regeneration system, which utilizes radial flow canisters filled with Centaur HP carbon. Several years ago, Calgon Carbon sold its odor control equipment division to Continental Carbon along with the Centaur HP carbon. The unit consists of 26 compartments of five canisters each for a total of 130 canisters. Foul air is delivered from the Screening Building by the odor control fan and is uniformly distributed through the carbon canisters, bringing the air in direct contact with the carbon. Centaur HP carbon contains a catalyst that oxidizes hydrogen sulfide (H_2S) and converts it to sulfuric acid. As a result, the carbon can be restored for H_2S uptake by water washing. The regeneration process consists of filling a single compartment of canisters with water, letting the water sit for a period of time, and then draining and drying the carbon. The system was installed in 2006. The carbon has not been replaced since installation.

This odor control system operates under air permit requirements (Permit to Install No. 69-90). The emission limit is 0.04 pounds per hour of H_2S . At a design air flow of 26,000 cubic feet per minute (cfm), this equates to approximately 0.3 parts per million volume concentration of H_2S . The permit does not require sampling of emissions of carbon media unless the Michigan Department of EGLE specifically requests it.

Per GLWA, no odor complaints have been received for at least the past three years.

6.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendations in this section are based on the Jacobs team evaluation of the existing system.

Future Carbon Replacement Considerations. Carbon eventually needs to be replaced when the capacity to remove H_2S diminishes to the point that the discharge does not meet permit limits. Carbon replacement can be expensive, and the frequency and type of carbon should be carefully considered. This section presents considerations for carbon replacement.

The Centaur HP carbon loses capacity over time for several reasons. The main mechanism is loss of adsorption sites due to compounds other than H_2S . Other odorous compounds like organic sulfide compounds remain adsorbed to the carbon and are not removed during the regeneration process. Chlorine and other compounds that may be present in the regeneration water will adsorb to the carbon and remain. Another mechanism is residual sulfuric acid that does not get rinsed during the regeneration cycle and remains on the carbon occupying sites. Finally, carbon fines (i.e., tiny pieces of the carbon media) are lost over time as a result of the repeated washing process. The loss of fines reduces the carbon volume, which, correspondingly, reduces the carbon's overall capacity. One typically determines the need for carbon regeneration by measuring the H_2S concentration in the discharged air. When H_2S is still detected in the discharged air after a regeneration cycle, the carbon is spent and should be replaced. Centaur HP replacement is about every two years under typical municipal wastewater applications. GLWA facilities are not typical applications as the odor control systems are operated infrequently and are likely under low loads from H_2S and odorous compounds meaning the carbon will last a lot longer. According to O&M staff, the Baby Creek system is regenerated twice per year based on the recommended PM in the manufacturer's O&M manual. If this frequency has occurred since startup, the system has been washed about 24 times. Under extremely low odor loads, the carbon can be depleted faster due to compounds in the regeneration water like chlorine. Laboratory analysis of the carbon for H_2S capacity is likely the best

way to determine the remaining carbon life for the Baby Creek system. Sampling the discharged air for H₂S breakthrough likely will not be effective due to the likely low H₂S load.

Although the current carbon capacity may be significantly less than the original capacity, the lack of any odor complaints from the community means that any odors being discharged are either not noticeable, not objectionable or are masked by other odor sources in the area. It is recommended that GLWA sample the influent and discharge of the odor control system during at least two storm events in the summer months (i.e., the period with the highest odor potential) to better understand the magnitude of odors generated from the CSO facility and the performance of the current system relative to the existing air permit limits.

If the influent H₂S levels are below discharge permit limits, replacement of the carbon would not be needed. Further testing could then be performed to determine if the carbon could be removed and not replaced. If influent and discharge H₂S levels are greater than permit limits, carbon replacement should be performed in the near future. The following bullets provides considerations for the carbon replacement.

- The existing Centaur HP carbon in the PHOENIX system has an H₂S capacity of 0.09 g H₂S/cubic centimeter of carbon (15 percent by weight). The cost for replacement of the carbon is about \$88,400 (130 canisters at \$680 per canister). The cost includes a new canister, sealing and loading the canister with Centaur HP carbon, and delivery.
- ECS Environmental Solutions (ECS) manufactures a direct equivalent to Centaur HP carbon at a lower cost. ECS reuses the existing canisters. The cost for ECS's water regenerable catalytic carbon is about \$55,250 (130 canisters at \$425 per canister). The cost includes shipping the full canisters to ECS, disposal of the spent carbon, cleaning the canisters, charging the canisters with ECS water regenerable catalytic carbon, and delivery.

As noted above, an evaluation of influent and discharge H₂S concentrations is recommended prior to carbon replacement. When it is time to replace the Centaur HP carbon, GLWA should evaluate replacing it with either Centaur HP or ECS water regenerable catalytic carbon.

6.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs".

6.2.4 Flushing and Dewatering

6.2.4.1 Description of Existing System

Dewatering System: After an overflow event, the effluent conduits and headworks area are dewatered by gravity by opening the sluice gates S-6-1 and S-6-2 to the Oakwood Interceptor. A 3,000 gpm dewatering pump is provided in the flushing pump area to fully dewater the Headworks area.

An alternate mode of dewatering is to allow the screening flushing pumps to continue to operate following an overflow event. This method of dewatering will allow dewatering flow into the Oakwood Interceptor even when the hydraulic grade line is relatively high.

Flushing System: A flushing system for the area in the Headworks upstream of the screens consists of two tipping buckets. There is one tipping bucket upstream of Screens 1-4 and one tipping bucket upstream of Screens 5-16.

It is noted that a flushing system is not currently provided for the effluent conduits. The nearly 1-mile long effluent conduits have an issue with significant quantities of solids accumulating in the channels (i.e., up to 5 ft deep in some locations). GLWA televised these conduits in 2019. GLWA plans to issue an RFP to address this issue in the near future. As such, this issue is not further addressed in this report.

Table 6-8 provides an overview of the existing flushing and dewatering system at Baby Creek CSO facility.

Table 6-8. Overview of Existing Flushing and Dewatering System at Baby Creek CSO facility

Parameter	Value
Headworks Dewatering and Flushing System	- One 3,000 gpm submersible pump for station dewatering (in Dewatering Sump) - Four 16,000 gpm submersible pumps - typically for screenings conveyance, but can be used to dewater area upstream of screens 2 tipping buckets for the area upstream of screens. Buckets flush toward Dewatering Sump, which pumps to Toward Treatment sewer
Effluent Conduit Dimensions	Three 17.5 ft × 14.5 ft barrel conduits
Effluent Conduit Dewatering and Flushing System	- Sluice gates at end of conduit are used to dewater effluent conduit to the Oakwood Interceptor after storm event. - There is no flushing system in the effluent conduit. <i>Project for a flushing system anticipated in the near future</i>

6.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids can accumulate in the influent channel area, immediately upstream of the weir wall at the Headworks. Significant solids buildup can cause hydraulic restrictions and impede inspection of influent flow meters. There is no flushing system at this location and solids removal must be performed periodically by a contractor. A contractor recently cleaned the influent channel area in 2019.
- S-2-1 sluice gate opening does not extend to the bottom of the influent channel to allow for complete dewatering (or solids flushing) of the influent area.
- Address sediment buildup in effluent disinfection conduits. Significant sediment occurs over time in the effluent conduits. An RFP for professional engineering services to minimize the buildup of sediments is planned in the near future to address this issue. As such, it is not included as a capital improvement project for CS-299.

6.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing System in Influent Area (Project BC-FD-1). There are two alternatives for addressing the solids buildup in the influent area and the S-2-1 sluice gate opening. These alternatives include:

- Alternative 1: Do Nothing/ Contractor Clean-Out.**
- Alternative 2: Flushing System in Influent Area.** An identified alternative includes mounting a 6- in. high-density polyethylene (HDPE) flushing header along the backwall of the influent area

approximately 8 ft above the adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B for figures (Figure BC-FD-1-ALT-2) showing conceptual layouts of this header. HDPE pipe is recommended for this application due to its corrosion resistance and its flexibility that imparts resistance to damage from impacts by heavy debris suspended in wet weather flows. The flushing header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 3/4- in. diameter) that create a water jet aimed in a specific direction toward the opening of Gate S-2-1. This gate is normally closed during dry-weather operation. A subsequent project to lower the invert of this opening is included in this set of recommendations.

The proposed hole spacing along the header is approximately 18 to 24 in. A total flow rate of at least 900 gpm is estimated to adequately remove sediment from the concrete shelf above the dry-weather flow channel and maintain adequate volume and velocity to carry the sediment into the dry-weather flow channel post event.

A second HDPE header mounted approximately 5 ft above the dry-weather flow channel with a similar spray hole distribution is recommended to provide additional flow and increase velocity during flushing. This will encourage faster removal and migration of sediment to the reconfigured Gate S-2-1 opening for pumping with the existing dewatering pump and discharge toward the WRRF with its better capacity for solids removal and disposal. A total flow rate of 1,200 gpm is estimated for initial sizing of this header. The benefit of the drilled hole approach to directing a jet of water is that no fittings are mounted on the exterior, and the pipe wall provides enough apparent length such that the hole directs the flow toward the intended surface.

Non-potable water (NPW) will be required. A 6-in. NPW line exists within the Headworks facility and is currently used for screen spray water and for chemical line flushing. The proposed flushing system connection could be made to this existing line within the facility. Flushing of the influent channel should occur after facility flows have significantly receded. As such, the influent flushing water use will not conflict with these other uses.

Following a CSO event, a motor operated solenoid/gate/ball control valve at the NPW pipe connection to the flushing water system will be opened to charge the flushing header. The control strategy assumes that solenoid is activated for a set duration (minimum of 15 minutes) after the level sensors in the influent channel record a water level rise above a pre-determined wet weather elevation and then a subsequent water level drop. A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying. Weekly automated cleaning during dry weather periods using this system will help reduce buildup of materials on the shelf and in the dry-weather flow channel.

During initial operation, onsite staff should visually inspect the shelf area to confirm sediment has been adequately removed and then adjust the control system timer to increase/decrease the flushing duration as needed until the system has been optimized. Integration with the facility's SCADA and PLC systems is necessary to achieve this functionality. A new electrical connection to the control valve is also required (110 V) and would be routed from the nearest internal junction box.

The opening for the S-2-1 gate does not extend to the floor of the influent channel. Making the bottom of this gate opening at a lower elevation would allow for flushed solids to enter the dewatering well and staff to be able to dewater the area without using sump pumps. The opening of sluice gate S-2-1 could be modified by removing the existing gate and frame, cutting approximately 2 ft of concrete from the bottom of the opening and remounting a new larger sluice gate.

The existing dry-weather flow channel will require addition of concrete topping to form a positive slope toward the expanded Gate S-2-1 opening, as shown in the drawings. The final designer should

collect and characterize site-specific sediment samples for grain size and density, and use a sediment fate/transport, CFD or scale model to finalize the performance criteria. This will be critical in evaluating and sizing this system to determine the required flow rate to direct sediment and the dry-weather base flow (20-30 cfs) toward the opening of Gate S-2-1.

The opening for the S-2-1 gate does not extend to the floor of the influent channel. Making the bottom of this gate opening at a lower elevation would allow for flushed solids to enter the dewatering well and staff to be able to dewater the area without using sump pumps. The opening of sluice gate S-2-1 could be modified by removing the existing gate and frame, cutting approximately 2 ft of concrete from the bottom of the opening and remounting a new larger sluice gate. Subsequent to the draft Facilities Assessment Report, another consultant (AECOM) analyzed this proposed flushing arrangement using CFD modeling and found that the proposed flow rate in the trough did not significantly suspend sediment within the influent trough. Based on this input, GLWA elected to postpone this project further into the future (at least 10 years out) and re-evaluate again after another round of manual cleaning.

For reference, the alternative evaluation for these alternatives is presented in Table 6-9. The sources of costs used in this evaluation are listed in the following bullets:

- Contractor clean-out of this area is estimated to be \$250,000 every 5 years, based on the cost and amount of solids buildup from the recent cleaning project at this location. This O&M cost is annualized to \$50,000.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$90,000 for cleaning the influent channel prior to installing the flushing system. The \$90,000 equates to about \$250,000 after contingencies, and standard markups for design, construction assistance and contractor overhead and profit have been applied.
- The O&M costs for the flushing system (Alternative 2) is based on water usage of 2,100 gpm for 15 min every week, for a total of about 1.6 MG per year and a unit cost of \$4,000 per MG.

Based on the results of recent CFD modeling of the flushing system by others showing that the sediment is not significantly suspended, **Alternative 1 – Contractor Clean Out is the recommended alternative.** Although Alternative 2 is not recommended at this time, it is included in the CIP to be reconsidered in about 10-15 years based on experienced gained from contracted cleaning the influent channel.

Table 6-9. Alternative Evaluation for Flushing System in Influent Area (Project BC-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Contractor Clean-Out	Health and Safety	2	2.50	\$ -	\$ 50,000	\$ 1,054,482	\$ 421,793	
	<i>Definition:</i>	Allow solids to build up and have a Contractor clean out the channel, as needed	Water Quality & Compliance	3						
	<i>Adv.:</i>	No system to maintain	Capacity Enhancement	3						
	<i>Disadv.:</i>	Significant build-ups can impact facility hydraulic capacity. Cleaning influent area is a high-risk activity. Requires a great deal of GLWA coordination.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing System in Influent Area	Health and Safety	5	3.78	\$ 787,000	\$ 6,400	\$ 921,974	\$ 243,693	Best Value Alternative
	<i>Definition:</i>	Mount a flushing header along the backwall of the influent area and second flushing header above the dry weather flow channel	Water Quality & Compliance	3						
	<i>Adv.:</i>	Allows flushing after every event.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance of equipment and increased water usage.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.5 HVAC

6.2.5.1 Description of Existing System

The Baby Creek CSO facility was constructed in 2006. The facility consists of one main building with a large Headworks, Chemical Room, utility support (two Electrical Rooms and a Mechanical Room), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building about a mile from the main building. Table 6-10 provides a summary of the major HVAC equipment at this facility.

Plumbing services for the facility consist of city water service, sanitary system, natural gas-fired water heater, electric water cooler, emergency shower/eye wash, emergency eye wash, and bathrooms with lockers and shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 6.2.10.

Table 6-10. Major HVAC Equipment at Baby Creek CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HV-1 & 2	2 × Heating and Ventilating Units	31,000 cfm and 1,760 MBH
	SF-1, 2, & 3	3 × Supply Fans	45,000 cfm
	EUH-1A to H	8 × Electric Unit Heaters	2,450 cfm and 51.2 MBH
Chemical Room	GUH-5A to 5E	5 × Gas Unit Heaters	1,100 cfm and 60 MBH
	IF-1	Exhaust Fan	2,110 cfm
	IF-2	Exhaust Fan	10,551 cfm
Electrical Room 1	WF-1	Wall Fan (Exhaust)	6,320 cfm
	EUH-2	Electric Unit Heater	700 cfm and 25.6 MBH
Electrical Room 2	WF-2	Wall Fan (Exhaust)	1,000 cfm
	EUH-3	Electric Unit Heater	400 cfm and 17.1 MBH
Control Room	HVAC-1	AHU with Split DX Cooling Coil and Natural Gas Furnace	1,610 cfm 74 MBH Heating 43.5 MBH Cooling
Office	HVAC-2	AHU with Split DX Cooling Coil and Natural Gas Furnace	1,480 cfm 74 MBH Heating 43.5 MBH Cooling

Notes:

AHU = air handling unit(s)

BTU = British thermal units

MBH = thousand British thermal units per hour

Table 6-11 provides a summary of the basis of design performance criteria for HVAC systems at Baby Creek and Table 6-12 provides the outdoor Basis of Design conditions.

Table 6-11. Baby Creek Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks	Class I, Div 1, Group D	60	N/A	12 ACH (Occupied)
Chemical Room	Unclassified	60	100	6 ACH (Cooling Mode) 1 ACH (Continuous)
Electrical Room	Unclassified	70	100	Heat Relief
Control Room	Unclassified	72	72	5 cfm per person & 0.06 cfm/ft ²
Office	Unclassified	72 (Occupied) 50 (Unoccupied)	75	5 cfm per person & 0.06 cfm/ft ²

Notes:

ACH = air changes per hour

cfm/ft² = cubic feet per minute per square feet

Table 6-12. Baby Creek Original Outdoor Basis of Design Conditions

Outdoor Design Temperature		
Winter (Dry Bulb F)	Summer (Dry Bulb F)	Summer (Wet Bulb F)
3	91	73

6.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC Contractor, the following HVAC issues were noted:

- Inadequate heating in Control Building: O&M staff noted that when outdoor air conditions are under 20 °F, the furnaces (HVAC-1 and HVAC-2) serving the main Control Building struggle to maintain a setpoint of 70 °F indoors.
- Abnormally short life for Electric Unit Heaters in Headworks Area: Per GLWA's HVAC Contractor, the Electric Unit Heaters in the Headworks Area have a life of 2 to 3 years. The typical expected life of unit heaters which are properly selected for their environment is about 15 years.
- Corrosion issues with Gas Unit Heaters in Chemical Room: GLWA's HVAC Contractor has observed corrosion issues with the gas unit heaters in the Chemical Room. Additionally, the location of one unit over the pump area was noted as making access for maintenance a major issue.

During site investigations (June 2020) the following observations were noted:

- The Chemical Room unit heaters are difficult to access. See Figure 6-3.

Figure 6-3. Chemical Room Unit Heater Located in Inaccessible Area

- Corrosion was visible on unit heaters in the Chemical Room.
- The Transformer Room supplied outside air for ventilation cooling high in the space and exhausted at a low level.
- The large overhead doors were open in the Headworks Area, the relief dampers were closed, and the make-up air unit (MAU) was not running.
- The thermostat on EUH-1 in the Headworks Area was out of calibration.
- Unit heater EUH-2 was turned on in the Headworks Area and it was about 75 degrees outside.
- Corrosion was visible on Trane unit heaters in the Headworks Area.
- Several of the motorized outside air intake dampers for SF-1, SF-2, and SF-3 were not functional. The fans showed signs of significant corrosion.

Improvements are currently ongoing under existing projects including:

- The installation of a new intake louver with integral motorized damper and exhaust fan in the Electrical Room
- Damper motor actuator replacements in the Chemical Room
- Damper and actuator replacements in the Headworks Area
- Various monitoring and control upgrades including control and monitoring of electric unit heaters, fans, dampers and HVAC units.

6.2.5.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Control Building HVAC Investigation and Improvements Study (Air Balance Study). Given that the winter outdoor design condition for the units was 3 °F and that they were designed to heat to 72 °F, the furnaces are not functioning as intended.

If the ongoing controls upgrade does not improve heating at the facility, Jacobs recommends an air balance of HVAC-1 and HVAC-2 to assess whether poor air distribution is the cause of the observed underheating.

If the air balance does not improve heating in the under-heated areas, electric duct heaters can be added to branches of the system requiring additional heat.

Chemical Room Unit Heaters and Ventilation System (Project BC-HVAC-1). The Trane GAND model unit heaters in the Chemical Room have aluminized steel heat exchangers. Sodium hypochlorite is known to have a severe corrosive effect on aluminum. The use of natural gas unit heaters in a sodium hypochlorite environment is generally not recommended due to the potential for corrosion of the unit heaters and subsequent natural gas leakage. There are two alternatives to address this issue:

- 1) **Alternative 1: Replace Chemical Room Unit Heaters and Ventilation System In-Kind.** This alternative assumes the units will be replaced in-kind. Because of the corrosive environment of this room, the units will be assumed to be replaced more frequently than typical unit heaters, as discussed further in the alternative evaluation in the following paragraph.
- 2) **Alternative 2: Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit.** This alternative involves removing the gas unit heaters and installing an air handling unit (AHU) with a modulating gas heating section at ground level adjacent to the Chemical Room. The unit would be provided with a VFD to allow the AHU to work in conjunction with IF-1 to maintain a set differential pressure between the Chemical Room and ambient conditions. The AHU would run in conjunction with IF-1 and IF-2 in the summer to provide ventilation for cooling the Chemical Room. The AHU would run continuously at the minimum ventilation rate but would also be provided with a low leakage motorized damper which would close when the unit is not running (when the unit requires maintenance) to prevent backflow of air from the Chemical Room to the inside of the AHU potentially leading to corrosion issues. Locating the heating section in an AHU on the ground level has the added benefit of both reducing the number of pieces of equipment which need to be maintained and providing easier access to the equipment for maintenance personnel.

Figure BC-HVAC-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows a potential location for the AHU. It also shows that the road next to the Chemical Room would need to be slightly relocated to allow adequate room for the AHU. Road modifications are included in the capital cost for this alternative.

The alternative evaluation is presented in Table 6-13. The sources of costs used in this evaluation are listed in the following bullets:

- Capital costs for the unit heaters and ventilation units in Alternative 1 were obtained from the SRP. The costs for the six unit heaters were multiplied by 2, assuming the units would need to be replaced twice during the life cycle of the AHU in Alternative 2.
- The annual O&M cost recognizes that there is less maintenance on the one AHU (Alternative 2) as opposed to the six unit heaters (Alternative 1).
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 is the Best Value Alternative. **As such, Alternative 2 Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit is the recommended alternative.** Since Alternative 1 consists of in-kind replacement of the unit heaters and ventilation equipment, these units will be included in the SRP, not a CIP project.

Table 6-13. Alternative Evaluation for Replace Chemical Room Unit Heaters and Ventilation System (Project BC-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Chemical Room Unit Heaters and Ventilation System In-Kind	Health and Safety	3	2.78	\$ 73,400	\$ 5,760	\$ 194,876	\$ 70,015	Best Value Alternative
	<i>Definition:</i>	Replace unit heaters in Chemical Room in-kind, with material compatible with corrosive atmosphere	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Multiple units require increased maintenance	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement of unit heaters 2 times during 20-year period. O&M assumes annual maintenance of 6 hrs per unit.	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit	Health and Safety	4	3.60	\$ 236,000	\$ 2,400	\$ 286,615	\$ 79,615	
	<i>Definition:</i>	Replace unit heaters in Chemical Room with a make-up air unit outside Room at ground level	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier access for maintenance, fewer units to maintain, protected from corrosive atmosphere	Capacity Enhancement	3						
	<i>Disadv.:</i>	Tight site constraints for MAU	Component Performance	4						
	<i>Comments:</i>	O&M assumes annual maintenance of 20 hrs for AHU.	O&M Ease	4						

Headworks Building Electric Unit Heaters. The Trane UHXA unit heaters in the Headworks Building have an aluminum-finned tubular steel heat exchanger which is directly exposed to the air stream in the Headworks Building when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating which has passed the ASTM B117 salt-spray test. Indeeco makes such a unit, which has been installed in other CSO facilities. Based on the information presented here, new unit heaters will not be a capital improvement project; rather they will be replaced as part of the SRP.

6.2.6 Electrical

6.2.6.1 Description of Existing System

The Baby Creek facility's electrical system consists of a double-ended unit substation with dual (redundant) utility feeds, primary metering and DTE Energy indoor dry type transformers. The substation has a tie-breaker and automatic source transfer controls. Circuit breakers in the substation then feed four motor control centers (MCCs). The MCCs then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Because of the redundant electrical feed, this facility does not have an emergency generator. Table 6-14 provides a summary of the major electrical equipment for this facility.

Table 6-14. Major Electrical Equipment at Baby Creek

Location	Major Electrical Equipment	Description
Electrical Room 1	Double-ended unit substation	2,000 kVA, 24 kV-480/277 V, 3 Phase
Electrical Room 1	MCC-1	1,200 A, 480/277 V, 3 Phase
Electrical Room 1	MCC-2	1,200 A, 480/277 V, 3 Phase
Electrical Room 2	MCC-3	800 A, 480/277 V, 3 Phase
Electrical Room 2	MCC-4	800 A, 480/277 V, 3 Phase

Note:

kVA= kilovolt-ampere(s)

6.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for less safe working conditions. These lighting needs are in addition to the recent LED lighting project. This issue is further described in the next section.

6.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project BC-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating bypass gates at night and when accessing area downstream of screens.

2) **Alternative 2: Electrical Improvements.** Add Lighting and Exterior Power Receptacles at the following locations (and shown on the electrical drawings - Figure BC-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):

- Downstream of mixers – Add the required amount of ceiling and wall mounted LED lighting fixtures to provide sufficient lighting for O&M activities.
- Light pole by bypass gates - Add light pole and associated LED lighting fixture at the facility's bypass gates.
- Exterior power receptacles are needed about every 75 ft on the front and back wall of the facility to assist in the maintenance and operations of the facility. Receptacles should be accessible from ground level.

The alternative evaluation is presented in Table 6-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$38,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 6-15. Alternative Evaluation for Electrical Improvements (Project BC-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating bypass gates at night and when accessing area downstream of screens.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 133,000	\$ -	\$ 133,000	\$ 38,000	Not Applicable
	<i>Definition:</i>	Add additional lighting and receptacles at identified locations	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Minor increased maintenance and energy usage with increased number of lights.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.7 I&C

6.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2005 under PC-748. The Ovation system was designed having two separate control systems – one for the CSO Facility and one for the Sampling Building. The CSO Facility's control system has the capability to control and monitor both systems; whereas the Sampling Building control system only monitors the outfall and controls the Miller gates. In 2015 under Job Order JB -173 the CSO Ovation system controllers and software were upgraded to O.V.3.5.0.

The existing CSO Facility Ovation system is composed of a typical Ovation control network with primary and backup network switches. The switches are connected to the GLWA AT&T wide area network via the system's router. It has three operator workstation stations, plus a database server. A redundant pair of Ovation controllers provides the station with controls and I/O capabilities. A 10 kilovolt-amperes (kVA) Liebert uninterruptible power supply is used to provide constant power to the network equipment and workstations. The network connections inside the facility are via copper Ethernet cables. The controller's connections are dual-homed, which means each controller has one connection to each of the network switches. Should one network fail, the backup, redundant network is available to provide station monitoring and control. The current system is equipped with a backup radio system to communicate critical monitoring points back to the System Control Center on wide area network failure.

The Sample Building's Ovation system consists of Ovation local I/O points, a controller, and a HMI that can only perform local control. Communications are via telephone line with radio backup to the CSO Facility. The local control panel is in poor condition and should be replaced in the near future due to reoccurring maintenance issues. The Sampling Building local control system was not updated in 2015 and is still operating on the old O.V.3.1. platform.

Flow and Level Sensors: Table 6-16 summarizes the level sensors and flow meters at the Baby Creek CSO facility used to monitor flows through the treatment system, chemical feed, and chemical storage.

Table 6-16. Summary of Flow Meters and Level Sensors at Baby Creek CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent (Elmer Ternes, East Barrel, West Barrel)	3	Transit-Time (AccuSonic)
CSO Level Sensors		
Influent (Elmer Ternes)	1	Ultrasonic
	1	Radar (Backup)
Influent (East Channel)	1	Ultrasonic
	1	Radar (Backup)
Influent (West Channel)	1	Ultrasonic
	1	Radar (Backup)
Screening Area (Upstream and downstream of screens)	6	Ultrasonic
	6	Radar (Backup)
Effluent Channel	1	Ultrasonic
	1	Radar (Backup)

Area	Quantity	Instrument Type
<i>Chemical System Flow Meters</i>		
Chemical Feed	2	Magnetic
Carrier Water	1	Magnetic
Service Water	1	Magnetic
<i>Chemical Storage Level Sensors</i>		
Chemical Storage Tanks	4	Ultrasonic

6.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Address influent screen VFD failures
- Evaluate level sensors to determine redundancy and identify level sensors that could potentially be removed
- Need for additional flow meters and level sensors to improve monitoring and control of facility flows during wet weather and dewatering phases and level monitoring of tank levels at the Chemical Fill Station
- Need for process cameras at select locations to improve monitoring of facility during wet weather operation
- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Update Ovation control system to the latest version and increased monitoring capabilities
- There is a lack of full monitoring and control of CSO facility from the Effluent Sample Building
- The facility bypass gates require manual operation. During large storm events, this takes on operator away from other activities. Providing remote control of these gates is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.

6.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project BC-I&C-1). Due to the relatively small nature of some of the I&C-related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation control system upgrade and the full monitoring and control capability of the entire facility from the Effluent Sample Building, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) Alternative 1: Do Nothing/Replace In-Kind.

- Replace screen VFDs in-kind or leave VFDs in bypass mode
- Leave redundant level sensors in place

2) **Alternative 2: I&C Improvements** including,

- Address influent screen VFD failures
- Remove redundant level sensors
- Provide additional flow meters and level sensor
- Provide process cameras at select locations
- Provide local remote control for screens

Each of the I&C-related improvements listed above is described further in the following paragraphs:

Address influent screen VFD failures. Operations staff indicated the VFDs running the influent screens are subject to regular failures. The failures occur intermittently and cannot always be reset from the VFD. Operators have the option of bypassing the VFD to operate the screens, but without the ability to control the speed. It should be noted that, the screens operate at 100 percent speed constantly.

A short-term, temporary solution to bypass the VFDs after a fault is available. Each of the influent screens is equipped with a bypass contactor separate from the VFD. A selector switch on the front of the influent screen control panel is used to select the “bypass” mode. While operating in bypass mode, the influent screens will run in the forward direction at full speed. The reverse jog pushbutton located in a control station on the process floor near each influent screen, which is intended to momentarily reverse the screens in the event of a jam, will not function while the screens are in bypass mode. The VFD is used to provide the reversing feature and is not available while being bypassed. Operations has indicated the reverse jog feature is never used, so operating the influent screens in bypass mode is an acceptable, temporary option.

For a long-term solution, the influent screen manufacturer should be consulted to determine the path forward and if VFDs are necessary. If the influent screens do not require VFDs to operate, the VFDs should be removed and replaced with constant speed starters, similar to operation while in bypass mode. A second, reversing contactor should be included and interfaced with the reverse jog pushbutton located at the influent screens. Internal wiring modifications and as-built record drawings should be included. If the VFDs are necessary for long-term operation, the VFDs should be replaced with modern units to avoid the intermittent VFD failures.

Remove redundant level sensors. During the January 2020 Facilities Assessment meetings with O&M staff, GLWA requested that Jacobs investigate existing level sensors at all facilities to determine where there was redundancy and identify level sensors that could potentially be removed to minimize the number of instruments. The main focus of this investigation was the level sensors throughout the CSO treatment process.

There are two sets of level sensors in the influent channel at Baby Creek. Each set contains a primary ultrasonic and backup radar level sensor. One set is for the southern end of the channel (near Screen 2) where the influent weir is at El. 91 ft and the other is at the northern end (near Screen 11) where the influent channel is at El. 92 ft. Figure 6-4 shows the locations of these sensors. Review of the historical Ovation data for a recent six-month period shows that these two sets of level sensors have nearly identical readings, and as such, one set could potentially be removed. If removed, this would provide one ultrasonic level sensor as the primary sensor and one radar sensor as the backup for the influent channel.

There are also several redundant level sensors immediately upstream and downstream of the screens. Figure 6-4 highlights the locations of these level sensors in the Headworks. The original intent of these sensors, as depicted in the piping and instrumentation diagrams, was to provide the differential level readings for banks of screens to indicate when the screen should turn on and the speed of the screen. GLWA (and previously Detroit Water and Sewerage Department) have not used this feature since the major screen blinding/failure issues shortly after facility startup. Currently, the screens are

turned on at high speed when needed and then turned off after the wet weather event. Also, the jog feature is reportedly not used by operations staff. The removal of these differential level sensors (in accordance with Figure 6-4) would prevent the jogging feature of the screen and the speed adjustment, both of which are not used.

Provide additional flow meters and level sensors. Operations staff requested additional flow or level monitoring at the following locations:

- **Outfall Level Sensor:** GLWA requested a level sensor at the outfall. Consistent with the level measurement technology in Section 5.4.3, a radar level instrument is recommended.
- **Effluent Conduit Flowmeter:** The flowmeter should not be an Accusonic model but should be a laser-based flowmeter such as a TieNet 360 LaserFlow Velocity meter.
- **Bypass Conduit Flowmeter:** It should be noted that Jacobs performed a more detailed assessment of a laser-based flowmeter (TieNiet360 LaserFlow Velocity meter) for this location. Although the cost of the flow meter itself is significantly less than that of an Accusonic meter, the total project cost was greater than expected due to the significant cost for the structure above the conduit to provide adequate room for proper flow measurement. This flow meter is not included in the cost estimate.
- **Chemical Fill Station:** Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Provide local remote control for screens. Provide local control for the screens in accordance with Section 5.4.9.

The alternative evaluation is presented in Table 6-17. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 includes VFD replacement for all screens and level sensors.
- The capital cost for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 include estimated annual maintenance of the valve control network. The O&M costs for Alternative 2 include estimated annual maintenance costs for the additional instrumentation provided.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative because the NPV/Benefit cost of Alternative 1 is approximately \$148,000 lower than that of Alternative 2. The total benefit score for Alternative 2, however, is 0.5 higher than Alternative 1 due to improved component performance and ease of O&M. **Since Alternative 2 provides increased performance and ease of O&M, it is the recommended alternative.** Due to the high NPV/benefit cost, however, it is not necessarily a high priority project if there are budget constraints.

Figure 6-4. Baby Creek CSO Facility Level Sensor Identification

Table 6-17. Alternative Evaluation for I&C Improvements (Project BC-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.78	\$ 347,600	\$ 4,500	\$ 442,503	\$ 158,983	Best Value Alternative
	<i>Definition:</i>	Replace screen VFDs and level sensors in-kind.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	O&M assumes annual maintenance of 5 hrs for level sensors; \$10,000 per year for valve network maintenance.	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 766,000	\$ 12,000	\$ 1,019,076	\$ 307,259	
	<i>Definition:</i>	Address VFD screen failures; removal of redundant level sensors; provide additional flow meters & sensors; provide process cameras; provide local control for screens	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	O&M assumes annual maintenance of 5 hrs for level sensors; 20 hrs for flow meter; 10 hrs for cameras.	O&M Ease	4						

Control System Upgrade (Project BC-I&C-2). This project updates the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2. A full list of control system upgrades at the Baby Creek CSO facility is included in the following bullets:

- Update Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.
- Replace the Sampling Building local control panel
- Update the Sample Building Ovation system to provide full control of the facility from the Sampling Building

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 6-18 provides the summary of the Control System Upgrade, which is the recommended alternative. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title.

Table 6-18. Alternative Evaluation for Control System Upgrade (Project BC-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,337,000	\$ -	\$ 1,337,000	\$ 445,667	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Replace Sample Building local control panel. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Updates the control system to allow for enhanced performance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

6.2.8 Site

6.2.8.1 Description of Existing Site

The Baby Creek Control/Headworks Building site includes a 20-ft wide concrete paved access road off of Dix Rd on the west side of the facility. A concrete paved parking area is located on the northwest side of the Control Building. Site pavement on both sides of the building consists of 10- in. concrete and 6- in. aggregate base. Site runoff is collected by a storm sewer network in the parking areas and in grassy areas on the perimeter of the site. Then the flow is conveyed to the combined sewers onsite. Site security around the perimeter of the facility is provided by 8-foot-high ornamental fencing. Access to the facility is controlled by a sliding security gate located at the northwest corner of the Control Building.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's geographic information system (GIS). Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, Global Positioning System (GPS) date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this section.

6.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following sections.

- The fence is damaged in some locations due to lawn mower strikes.
- The existing access hatch to the Baby Creek sewer requires a crane to remove concrete planks. This is being addressed in an ongoing "Baby Creek Outfall Improvements" project (CIP 277001).
- An additional access point is needed downstream of the Screens 1-4.
- The stop logs are currently stored out-of-doors at the facility. The stop logs rubber seals are damaged by sunlight and, subsequently, are not effective when needed for flow isolation.
- The existing entrance gate is a 24-foot-wide cantilever sliding ornamental gate. The gate has experienced frequent electrical issues and has remained out of service for extended periods of time awaiting repair. During periods when the gate is out of service, it remains in an open position, which is a security concern particularly during hours of the day when there are fewer staff at the site. This was addressed in late 2020 under the GLWA-Contract No. 2001372 – Task 25 "Baby Creek Entrance Gate Repairs & Improvement" project.
- The following needs are generally PM items intended to ensure that the site features and utilities are serviceable throughout their expected service lives. These needs are listed in the following bullets and are not included in the capital improvement projects for CS-299. It is recommended that these issues be addressed by a GLWA-wide facilities maintenance contract. If not addressed.
 - Seal concrete pavement joints to prevent water infiltration

- Caulk expansion joint at the base of Control and Headworks Buildings between the walls/sidewalks along the north, south and west sides of the buildings
- Repair cracks in access drive and sidewalks

6.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Repair Security Fencing and Add Concrete Maintenance Strip (Project BC-SITE-1). The existing security fencing consists of 8-foot- tall powder coated aluminum fencing with 1- in. square fencing pickets. The total length of fencing is approximately 1,920 ft. The bottom of the fencing panels have experienced damage at several locations due to lawn mower strikes (example of damaged fencing shown in Figure 6-5). The impacts have left the bottom 6 to 8 in. of the pickets and posts severely bent or broken off. The fence is about 14 years old and, aside from the damaged pickets, remains in good condition. The damage sustained by the fencing does not currently impact security; however, because several fence posts have been damaged the fencing integrity in those areas has been compromised. There are two alternatives for addressing this issue. These alternatives include:

- 1) **Alternative 1: Do Nothing.** Repair bottom of fence, as necessary.
- 2) **Alternative 2: Repair Security Fencing and Add Concrete Maintenance Strip.** this alternative replaces the damaged fencing panels and posts. To avoid future damage by lawn mowing equipment, it is recommended that a maintenance strip be established 2 ft from each side of the fence line to avoid future strikes. The concrete maintenance strips beneath the fencing appear to have worked well at other sites.

Figure 6-5. Example of Damaged Fencing at Baby Creek CSO Facility

The alternative evaluation for these alternatives is presented in Table 6-19. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to the limited extent of damage to the fence (i.e., only at the bottom), it is recommended that the fence be repaired, as necessary, and replaced when it has reached the end of its useful life. **As such, Alternative 1 is the recommended alternative.**

Table 6-19. Alternative Evaluation for Security Fencing (Project BC-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Replace fence in-kind at the end of useful life	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lowest cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Minor security concern	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Repair Fencing and Add Concrete Maintenance Strip	Health and Safety	3	3.20	\$ 226,000	\$ -	\$ 226,000	\$ 70,625	Not Applicable
	<i>Definition:</i>	Repair damaged fence and provide a concrete maintenance strip under fence to prevent future damage.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Addresses minor security concern	Capacity Enhancement	3						
	<i>Disadv.:</i>	Capital expenditure	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	3						

Stop Log Storage Shelter (Project BC-SITE-2). The stop logs are currently stored out-of-doors onsite at the Baby Creek CSO facility. The stop logs are equipped with compressible rubber seals that are susceptible to damage as a result of prolonged exposure to ultraviolet (UV) light. This results in their premature aging, impacting their ability to effectively prevent leakage when installed in the sewer stop log guides. The stop logs are currently stored in an area located between the Woodmere Pumping Station and the Baby Creek Headworks building, which has a footprint of approximately 60 ft by 20-ft. The stop logs are stored on grade and stacked next to each other. The stop logs rubber seals are damaged by sunlight and, subsequently are not effective and leak. There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing.** Continue to store stop logs outside.
- 2) **Alternative 2: New Stop Log Storage Shelter and Racks.** The purpose of a new storage shelter is to provide protection for existing isolation stop logs. The storage shelter must provide protection from UV light and exposure to the elements, but its design must also remain open enough to allow equipment to access and move the stop logs in and out of the shelter. Per discussions with GLWA, the new shelter is to be located in the same general area as the existing storage area.

There are two potential styles of structure that could be used for a stop log shelter: a pavilion style pitched roofed structure or a semi-permanent canopy style structure. The pavilion style structure is generally a steel truss and post framed structure with a steel panel roof but generally without permanent sidewalls. The canopy structure can be a steel or aluminum framed structure with a heavy-duty PVC or polyethylene fabric cover that covers the entire framing structure to ground level. Either structure can be designed to meet Michigan Building Code requirements for snow and wind loads. The canopy style structure would provide additional UV protection with covered sidewalls extending to grade and is recommended for the storage of the stop logs. In addition, this option is less permanent than a pavilion structure, in the event that this structure might need to be moved around within the property. See Figure BC-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B, for the location of the proposed stop logs storage shelter. The figure also shows conceptual photos of what this type of semi-permanent low-tech structure would look like.

To avoid storage of stop logs directly on grade, it is also recommended that the shelter be placed on a concrete pad and the stop logs be stored in racks. These items are included in the cost estimate in BC-SITE-2 in Volume 6 – Appendices, Appendix C under this project title.

In addition, GLWA also requested that a new access hatch be provided to allow access for the area downstream of Screens 1 to 4. This hatch will be located outside of the facility near the existing concrete pavement above the channel (Figure BC-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B), provides the approximate location. Soils will be excavated above the existing roof near the outer channel wall to allow installation of a new 4-foot by 4-foot accessway and fall-restraint type ladder. The roof slab will be sawcut, and a precast utility vault section set and affixed. This opening size is required to accommodate the ladder assembly to the surface, clear space for personnel entering/exiting the lower facility and adequate space for personnel extraction connections to move freely between the lower facility and surface. A locking traffic-rated hatch (HS-20) is recommended. The existing pavement section will be extended to this new hatch location to provide a clean, paved working surface for topside activities while manned-entry into the lower area is underway.

The alternative evaluation for these alternatives is presented in Table 6-20. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – New Stop Log Storage Shelter and Racks has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and improved O&M provided by protecting the rubber seals on the stop logs. The NPV/Benefit cost for Alternative 2 is \$145,000, which is a relatively high cost compared to other projects

recommended in this assessment. Based on this information, **Alternative 2 - New Stop Log Storage Shelter and Racks** is recommended; however, it should be a relatively lower priority than other projects.

Table 6-20. Alternative Evaluation for Stop Log Storage (Project BC-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to store stop logs outside	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lowest cost.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Rubber seals may not properly hold back water when needed for projects.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	New Stop Log Storage Shelter and Racks	Health and Safety	3	3.42	\$ 497,000	\$ -	\$ 497,000	\$ 145,463	Not Applicable
	<i>Definition:</i>	New storage shelter will provide protection from UV light exposure.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Rubber seals should last longer.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost.	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.9 Architectural

6.2.9.1 Description of Existing Facilities

The Baby Creek CSO facility consists of one main building with rooms for the process systems (screening and chemical feed/storage), odor control, utility support (electrical and mechanical), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building about a mile from the main building.

6.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. The facility has a shingled roof. About one-third of the roof surface was replaced in 2017. A recent (2020) assessment by a roofing contractor (Schreiber) indicated that the remaining two-thirds was in “poor” condition and there have been leaks into the Electrical Room during recent rain events. GLWA requested that Jacobs perform a cost comparison of replacing the shingled roof with a metal roof.

Jacobs reviewed the results of the roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows a lower life-cycle cost for shingled roof, Jacobs recommended replacement of two-thirds of the roof with shingles. The analysis is presented in Table 6-21. Subsequently, GLWA requested that drawings and a roof replacement specification be developed to use in contracting for roof replacement. This project should be completed in 2021. As such, it is not included in this report as a future capital project. The SRP model was manually adjusted to recognize the improvement of this ongoing project.

Table 6-21. 60-Year Life-Cycle Cost Evaluation of Shingled vs. Metal Roof for Baby Creek Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$649,000	\$2,163,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life-Cycle Cost (NPV) Discounted at 2.4%	\$1,762,000	\$2,163,000

^a Based on 43,250 ft² roof area; \$15/ ft² for shingle roof and \$50/ ft² for metal roof.

Note:

ft² = square feet

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities under CS-299. Jacobs used the architectural-related information in NTH’s Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the aboveground buildings as a starting point and included additional items, as observed during the assessments conducted under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that the floor coating in the Chemical Room had been consumed by sodium hypochlorite spills and the floor was flat and did not slope toward the sump.

6.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (BC-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessment. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Repair and replace cracked guardrail member; make unstable base connections for FRP guardrail more rigid
 - Address door and door frame corrosion issues, and door hardware issues for various doors
 - Clean localized rusted areas of structural steel surface and recoat localized steel areas in Headworks
 - Clean rusted areas of steel bollards and recoat all exterior bollards
 - Remove and replace, in kind, disbonded tile and underlayment from concrete floor
 - Repair/ patch finish material and repaint ceiling of entryway exterior canopy
 - Clean corrosion in steel base/ steel column supporting the entryway exterior canopy and repaint

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure BC-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 6-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the need to prevent more costly damage in the future from not addressing these issues, **Alternative 2 - Architectural Rehabilitation is the recommended alternative.**

Table 6-22. Alternative Evaluation for Architectural Rehabilitation (Project BC-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 596,000	\$ -	\$ 596,000	\$ 192,258	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

Slope Chemical Room Floors and Add Coating (Project BC-ARCH-2). GLWA requested Jacobs evaluate modifying the floor slope in the Chemical Room to drain to the sump. There are three alternatives evaluated:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Corrosion-Resistant Floor Coating in Chemical Room** (on existing flat floor). This alternative only provides a floor coating which is currently being considered to address an immediate need for floor protection. Jacobs has successfully used the following highly chemical-resistant coating systems in sodium hypochlorite containment areas:
 - Surface Preparation: Meet requirements of Society for Protective Coating SP 13 and coating manufacturer's instructions.
 - Primer: 1 coat of the manufacturer's recommended concrete primer.
 - Filler/Surfacer: 1 coat as required to fill voids of trowel grade filler and surfacer designed for vinyl ester coating.
 - Finish: 2 coats of vinyl ester coating resistant to containment service of 12.5 percent sodium hypochlorite solution. Provide slip resistant surface on floors.
- 3) **Alternative 3: Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room.** This alternative includes sloping the floor before adding the coating described in Alternative 2. Sloping the floor would be accomplished by grouting over the existing floor. Grouting should be coordinated with the chemical feed system replacement project, if possible. Coating of the floor should be done after increasing the floor slope.

The alternative evaluation is presented in Table 6-23. The capital costs for Alternative 2 and 3 are included in Volume 6 – Appendices, Appendix C under this project title.

As shown in Table 6-23, Alternative 2 has a Total Benefit score about 1.0 higher than Alternative 1 because of the chemical resistant coating protecting the concrete floor. Alternative 3 has a Total Benefit score about 1.2 higher than Alternative 2 based on the improved health and safety, component performance, and ease of O&M with the chemical resistant coating and the sloped floor. Coating the floor is necessary to protect the concrete floor over the life of the facility. Examination of the NPV/benefit costs for the alternatives that provide a coating (Alternatives 2 and 3) shows that Alternative 3 has the lowest cost. **As such, Alternative 3 - Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room is the recommended alternative.**

This project should be scheduled with future improvements to the chemical feed system. If these improvements do not occur within the next two to three years, consideration should be given to coating the existing floor to preserve the condition of the concrete.

Table 6-23. Alternative Evaluation for Slope Chemical Room Floors and Add Coating (Project BC-ARCH-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	1	2.02	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Concrete floor continues to deteriorate.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Corrosion Resistant Floor Coating (on existing flat floor) in Chemical Room	Health and Safety	2	3.03	\$ 283,000	\$ -	\$ 283,000	\$ 93,297	Not Applicable
	<i>Definition:</i>	Provide corrosion resistant floor coating on existing floor	Water Quality & Compliance	3						
	<i>Adv.:</i>	Protects concrete floor from damage due to aggressive chemical	Capacity Enhancement	3						
	<i>Disadv.:</i>	Chemical still stays on the floor for extended period.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4

	<i>Comments:</i>	Project should be combined with major disinfection project	O&M Ease	5						

6.2.10 Safety

6.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

6.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 6-24. The capital improvement project to address these issues is included in the table.

Table 6-24. Identification of Capital Improvements for Safety Issues

Location	Description	Proposed Corrective Action	Capital Improvement Project
Sample Room	Door needs illuminated exit sign	Add exit sign	Exit Sign Improvements ^a
Mechanical Room	No illuminated exit sign on exterior door	Add exit sign	Exit Sign Improvements ^a
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project BC-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

6.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section.

Safety Improvements (Project BC-SAFE-1). This project should address the safety issues identified above. These issues include:

- Fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 6-25 shows the one alternative.

Table 6-25. Alternative Evaluation for Safety Improvements (Project BC-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 236,000	\$ -	\$ 236,000	\$ 78,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection and eye washes.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

6.2.11 Supporting Infrastructure

6.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

6.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Inefficient mixer removal system – includes evaluation of monorail vs. gantry cranes with electric hoist and electric trolley to replace existing hand chain hoist.
- Address inability of overhead crane to access dewatering pump.
- Address high iron sediment concentration in potable water lines. GLWA has experienced high iron concentrations in incoming potable water to the facility. In August 2020, flushing of the incoming 8-in. water mains servicing the facility conducted under CS-299 in an effort to remove the cause of the rust colored water within the facility. A few weeks after the flushing exercise, the operators reported rust colored water again. Based on the results of the flushing samples and the return of the rust color, the following recommendation were made to minimize the iron in these lines:
 - For the eye wash in the Chemical Room, it is recommended to install an automatic solenoid valve on a timer to routinely flush this line for a set period of time each day. The operators could do this over a few consecutive days to find out how long it takes to flush the line before the iron dissipates. If it takes a long time and there is a large amount water on the floor, there should be consideration to providing a permanent drain to the sump. However, the results seem to indicate the iron color may dissipate quickly, especially if it is flushed routinely.
 - For the kitchen, a point of use device could be installed specifically designed for iron removal.

These projects could be done by GLWA maintenance and are not included in the capital improvements.

6.2.11.3 Discussion and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Improve Mixer Removal System (Project BC-SUPP-1). The overhead bridge crane was not designed with adequate side-to-side reach for removal and installation of the induction mixers. Currently, portable A-frame gantry cranes with hand chain hoists are used for this purpose. An improved mechanism for removing and installing the induction mixers is desired.

Three alternatives are identified in the following list:

- 1) **Alternative 1: Do Nothing.** Continue to use gantry cranes with hand chain hoists.
- 2) **Alternative 2: Monorail System.** Provide two parallel monorails centered over the two pairs of induction mixers in each mixing zone. The monorails would run the length of the building (or shorter monorails could be provided serving one or more of the mixing zones). Two continuous monorails the

length of the building were assumed for estimating cost. One ¼ ton electric hoist with manual trolley on each of the two parallel monorails was assumed for estimating cost.

- 3) **Alternative 3: A-Frame Portable Gantry Cranes with Electric Hoists.** Provide two new portable A-frame gantry cranes with a ¼ ton electric hoist and trolley on each.

The alternative evaluation is presented in Table 6-26. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. The table shows that Alternative 3: A-Frame Portable Gantry Cranes with Electric Hoists provides a Total Benefit score of 1.0 higher than the Do Nothing alternative because of improvement safety and ease of O&M. The table also shows that the NPV/Benefit cost is more reasonable than the Alternative 2 – Monorail System. **As such, Alternative 3 is the recommended alternative.**

Table 6-26. Alternative Evaluation for Improve Mixer Removal System (Project BC-SUPP-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use gantry cranes with hand chain hoists	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Raising mixer out of channel for inspection is more difficult and less safe.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Monorail System	Health and Safety	5	4.00	\$ 998,000	\$ -	\$ 998,000	\$ 249,500	Not Applicable
	<i>Definition:</i>	Provide two parallel monorails centered over the two pairs of induction mixers in each mixing zone. One ¼ ton electric hoist with manual trolley on each of the two parallel monorails.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Raising mixer out of channel is easier and safer.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Highest cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						
3	<i>Alt. Name:</i>	A-Frame Portable Gantry Cranes with Electric Hoists	Health and Safety	4	3.50	\$ 266,000	\$ -	\$ 266,000	\$ 76,000	Not Applicable
	<i>Definition:</i>	Provide two new portable A-frame gantry cranes with a ¼ ton electric hoist and trolley on each.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Raising mixer out of channel is easier and safer than existing operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not as easy as monorail system.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Overhead Crane Access for Dewatering Pump (Project BC-SUPP-2). O&M staff indicate that the existing building's overhead crane is unable to remove the dewatering pump. This is because the overhead crane travel does not reach the mid-point of the rails for the submersible dewatering pump. In order to use the overhead crane, the hook must be able to pull the dewatering pump straight up the rails, or the pump will not be able to be removed. Figure 6-6 illustrates this issue.

Two alternatives are identified in the following list:

- 1) **Alternative 1: Do Nothing.** Continue to use gantry crane. The gantry crane does not fit well into the space, making it difficult to remove the pump.
- 2) **Alternative 2: Add Trolley to Overhead Crane:** Jacobs contacted Crane Technologies, the original crane supplier for solutions to this issue. They recommended a 2-ton capacity electric chain hoist with motorized trolley. The hoist would be powered from a festoon track system that would have to be installed on the crane bridge. The hoist would be controlled from either a dedicated hard wire pendent, (which would have the concern for that pendent hanging down when the crane bridge is traveling down the runway), or from a dedicated radio control device, which would eliminate the corded pendent. The radio control system is recommended. The system would be explosion-proof rated.

Figure 6-6. Overhead Crane Issue

The alternative evaluation is presented in Table 6-27. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. The table shows Alternative 2 has a Total Benefit score of 1.5 higher than the Do Nothing Alternative because of improved safety and ease of O&M. The NPV/Benefit cost for Alternative 2 is about \$22,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety and O&M with this alternative, Alternative 2 – Add Trolley to Overhead Crane is the recommended alternative.**

Table 6-27. Alternative Evaluation for Overhead Crane Access for Dewatering Pump (Project BC-SUPP- 2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to utilize gantry crane to remove dewatering pump	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Extremely tight site conditions make positioning the gantry crane difficult, and potentially unsafe.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Add Trolley to Overhead Crane	Health and Safety	5	4.00	\$ 90,000	\$ -	\$ 90,000	\$ 22,500	Not Applicable
	<i>Definition:</i>	Add a 2-ton capacity electric chain hoist with motorized trolley	Water Quality & Compliance	3						
	<i>Adv.:</i>	Simplified pump removal and install	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

6.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Baby Creek CSO facility, Table 6-28 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 6-28, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 6-28. Listing of Asset Condition Assessments for Baby Creek Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

VALVE	56	56	0	100%
WATERHTR	2	2	0	100%

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The five Roof Ventilators (non-motorized) on the roof were not accessible

^c The two Make Air Units are duplicates of the HV-1 and HV-2 Air Handling Units. These MAUs should be deleted in the future.

^d The two post-screening pumps are not in service and were not assessed.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Baby Creek Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

6.3 Capital Planning for Baby Creek CSO Facility

6.3.1 Summary of Capital Improvement Plan Projects

Table 6-29 provides a summary of the recommended CIP projects and associated capital costs for the Baby Creek CSO facility based on the alternative evaluations conducted for this facility.

Table 6-29. Summary of Recommended Projects at Baby Creek CSO Facility

Project No.	Alternative	Description	Total Project Cost
BC-DIS-1	3	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 1,237,000
BC-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 201,000
BC-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
BC-FD-1 ^a	2	Flushing System in Influent Area	\$ 787,000
BC-ELEC-1	2	Electrical Improvements	\$ 133,000
BC-I&C-1	2	I&C Improvements	\$ 766,000
BC-I&C-2	1	Control System Upgrade	\$ 1,337,000
BC-SITE-2	2	New Stop Log Storage Shelter and Racks	\$ 497,000
BC-ARCH-1	2	Architectural Rehabilitation	\$ 596,000
BC-ARCH-2	3	Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room	\$ 338,000
BC-SAFE-1	1	Safety Improvements	\$ 236,000
BC-SUPP-1	3	A-Frame Portable Gantry Cranes with Electric Hoists	\$ 266,000
BC-SUPP-2	2	Add Trolley to Overhead Crane	\$ 90,000

Note:

^a Although this project is not recommended at this time, it is included in the CIP to be reconsidered based on experience gained from contractor cleaning of the influent channel.

6.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 6-30. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 6-30. Capital Improvement Plan Projects for Baby Creek CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
BC-1 Disinfection System Improvements	\$1,785,000	2033 <i>Timing based on existing asset condition</i>	BC-DIS-1	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 1,246,000
			BC-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 201,000
			BC-ARCH-2	Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room	\$ 338,000
BC-2 Influent Flushing System^a	\$ 787,000	2036 <i>Project to be re-evaluated after another cleaning cycle of the influent area</i>	BC-FD-1	Flushing System in Influent Area	\$ 787,000
BC-3 Facility-Wide Electrical and I&C Improvements	\$ 2,723,000	2025 <i>Timing based on asset condition</i>	BC-I&C-1	I&C Improvements	\$ 766,000
			BC-I&C-2	Control System Upgrade	\$ 1,337,000
			BC-ELEC-1	Electrical Improvements	\$ 133,000
BC-4 Facility-Wide Safety and Architectural Improvements	\$ 829,000	2023 <i>Project should be initiated as soon as possible</i>	BC-SAFE-1	Safety Improvements	\$ 229,000
			BC-ARCH-1	Architectural Improvements	\$ 600,000
BC-5 New Stop Log Storage Shelter	\$ 497,000	2030 <i>Timing based on best judgement</i>	BC-SITE-2	New Stop Log Storage Shelter and Racks	\$ 497,000
BC-10 Model Disinfection Performance	\$ 50,000	2021 <i>Timing based on potential for major maintenance cost reduction</i>	BC-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000

Note:

^a Although this project is not recommended at this time, it is included in the CIP to be reconsidered based on experience gained from contractor cleaning of the influent channel.

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 6-31 and Table 6-32 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 6-32 indicates that BC-DIS-1 project has two assets that need to be replaced immediately due to condition score of "5". These assets, however, have already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining 40 assets that are included in this project have an average condition score of 1.55 and an average replacement date of 2034 (See Table 6-31). This information was used to propose a scheduled construction completion date of 2033.

Table 6-31. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BC-DIS-1	40	1.35	1.55	2.43	21	2034	\$ 1,065,500
BC-DIS-3	29	1.29	1.24	2.08	10	2030	\$ 1,450,000
BC-HVAC-1	7	1.14	1.59	2.05	16	2032	\$ 39,801
BC-I&C-1	24	1.38	1.46	2.37	11	2031	\$ 329,307
BC-I&C-2	3	1.57	1.38	2.70	10	2030	\$ 803,097
BC-SAFE-1	2	1.71	1.29	2.82	10	2030	\$ 25,336
BC-SITE-1	1	1.29	1.33	2.14	20	2039	\$ 391,500

Table 6-32. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BC-DIS-1	2	1.29	5.00	4.50	10	2021	\$ 102,000
BC-DIS-3	3	1.29	5.00	4.50	10	2021	\$ 150,000
BC-HVAC-1	1	1.14	5.00	4.00	15	2023	\$ 4,800
BC-I&C-1	1	1.43	5.00	5.00	10	2021	\$ 18,300
BC-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -
BC-SAFE-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
BC-SITE-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

There are a number of recommended capital improvement projects presented in Table 6-29 that could be better delivered under capital outlay projects. These projects are listed in the following bullets:

- A-Frame Portable Gantry Cranes with Electric Hoists (BC-SUPP-1)
- Add Trolley to Overhead Crane (BC-SUPP-2)

For the CFD Modeling of Mixers (BC-DIS-3), it is ultimately recommended to include this project with similar modeling projects at the Conner Creek and Leib CSO Facilities. See Section 2 (Volume 1 – Project Introduction and Capital Improvement and Outlay Plans) for proposed bundling of this project.

6.3.3 20-Year Capital Outlay Plan

Table 6-33 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 6-33. 20-Year Capital Outlay Plan for Baby Creek CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 501,900	\$ 25,000	\$ -	\$ -	\$ 252,000	\$ -	\$ -	\$ 224,900	\$ -	\$ -	\$ -	\$ -	\$ -

Notes:

Explanation of large capital outlays in first two years:

- Screening System: Screen No. 1 was out of service at the time of the Condition Assessment for major repair and received a score of 5. It has since been put back into service and could be reassessed.
- Disinfection System: Three mixers (\$50,000 each; \$ 150,000 total) were missing/out of service at the time of the Condition Assessment. Also, two chemical feed pumps (\$51,000 each; \$102,000 total) were missing.
- HVAC System: The Air Handling Unit (HV-2) was not operational two different times during the Condition Assessment. Unit was new in early 2020. It has since been fixed. Also, there was one unit heater in the Chemical Room that was out of service.

7. Belle Isle CSO Control Facility

7.1 Existing Facility Description and Future Capacity Considerations

7.1.1 General Facility Description

The Belle Isle CSO Facility is an RTB with 300,000 gallons of storage and a treatment capacity of 33 cfs. It was constructed in 2007. The facility consists of a headworks, chemical room, odor control room, electrical room, mechanical room, control room, sample room, and restrooms. The facility also includes an adjoining Belle Isle Pump Station, which is not included in this facility assessment.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

7.1.2 Future Capacity Considerations

Jacobs recommends an evaluation of sewer separation on Belle Isle be conducted in an effort to reduce or eliminate treatment of wet weather flows.

A review of the Belle Isle Basis of Design shows that sewer separation was considered as an alternative to constructing a regional treatment basin (RTB). In 1998, there was a concern that stormwater treatment at a single location may be required. As such, 8,100 ft of storm sewer piping was included in the cost comparison for the sewer separation alternative. Given the current movement toward green infrastructure, stormwater treatment does not appear to be a concern, particularly for a natural location such as Belle Isle.

A study of current wet weather flows and inflow and infiltration for the Belle Isle sewer system should be conducted to determine whether sewer separation and infiltration and inflow (I&I) control could reduce wet weather flows sufficiently to completely eliminate the need for the RTB (i.e., screening, disinfection, storage, and odor control). If I&I cannot be reduced enough to eliminate the need for the RTB, flows should be reduced enough so that the facility could operate as a complete capture facility. This would eliminate the need for disinfection, screening (potentially), and operator involvement during storm events.

7.2 Facility Assessment

7.2.1 Screening

7.2.1.1 Description of Existing System

The Belle Isle CSO Facility has two perforated horizontal band screens that were installed in 2007. Screenings that are captured by the screens are pumped by the Screenings Recirculation Pumps back to the Belle Isle Pump Station, where they are conveyed by the sanitary pumps to the Detroit River Interceptor (DRI), and ultimately to the WRRF.

Table 7-1 provides an overview of the existing screening system at Belle Isle CSO facility.

Table 7-1. Overview of Existing Screening System at Belle Isle CSO Facility

Parameter	Value
Treatment Capacity (cfs)	33
Number of Screens	2

Parameter	Value
Manufacturer	JWC Environmental
Screen Type	Horizontal Band Screen
Opening Size	6-mm perforation
Depth or Length / Width	7 ft 8 in. / 2 ft 8 in.
Screen Cleaning	Brush and high-pressure spray
Screening Removal	Screenings pumped to Pumping Station and conveyed to DRI and to WRRF

Note:

in. = inch(es)

7.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- Existing band screens are difficult to maintain due to tight site conditions

7.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screen Replacement (Project BLI-SCR-1). The existing band screens perform well but maintenance is difficult due to their location under the grating and tight site conditions. The existing JWC Environmental horizontal band screens have 6-millimeter (mm) perforations. There are two alternatives:

- Alternative 1: Replace Existing Band Screens In-Kind.** This alternative would generally replace the existing band screens in-kind.
- Alternative 2: Replace Existing Screens with Fine Bar Screens.** A vertical fine bar screen was evaluated as a replacement. A vertical screen will provide adequate screening while being much more accessible for maintenance. Duperon's FlexRake FPFS-F fine bar screen was used as a representative screen and has 0.25- in. (approximately 6 mm) spacing. While a 6-mm perforation is finer than a 0.25-in. bar screen gap, both screens should provide equivalent screening. Michigan EGLE approval would be necessary for the 0.25-in. bar screen.

A vertical bar screen will require modifications to the existing channel. Currently, water enters the channel and flows up through the screen and over a weir as shown by the flow direction arrows on Figure 7-1. The existing screens extend approximately halfway across the channel. The vertical bar screen will extend across the full channel. Figure 7-2 shows the plan view of two vertical screening options. Option 1 positions the screen approximately halfway down the channel length while Option 2 positions the screen at the end of the channel where it leans up against the existing fiberglass screening retention baffle wall. A steel beam is needed to support the screen with both options. Duperon's screen may be completely vertical or at an angle of up to 45 degrees. The existing weir must be removed and filled in with concrete to prevent bypassing at high flows due to the long length of the existing weir. An opening downstream of the screen and cut into the concrete is necessary to convey the discharged flow. Option 2 requires an angled screen position and flow must discharge through a triangular opening.

Figure 7-2 also shows a 6-in. to 1-foot concrete bump out from the west wall extending the full channel depth for screen maintenance access. Positioning the screen at the end of the channel (Option 2) allows for screenings to discharge over the existing screening retention baffle wall into the screening wet well. Option 1 will require a screening sluice to convey screenings from the screens to the screening wet well. Figure 7-3 shows the sluice option. Headloss through the screen at the design flow of 16.5 cfs with 25 percent blinding is 0.04 in. Headloss through the existing JWC Environmental screen is unknown.

The alternative evaluation is presented in Table 7-2. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 1 were obtained from the screen replacement costs of the Scheduled Replacement Plan (SRP).
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C, under this project title.

This evaluation shows that Alternative 1 is the Best Value Alternative. Although maintenance would be easier for the proposed screen in Alternative 2, the difference in O&M costs were not calculated because the difference in capital costs is nearly \$1,000,000. Annualized over 30 years, this represents about \$51,000 (at 3 percent interest rate). It is unlikely the annual maintenance savings would be this high.

Because of the large difference in capital costs between the two alternatives, **Alternative 1 - Replace Existing Band Screens In-Kind is the recommended alternative**. As such, the replacement of these screens is not included in the CIP projects; rather it is included in the SRP.

Figure 7-2. Belle Isle Screening Channel Modifications

Figure 7-3. Illustration of a Screening Sluice for Belle Isle

Table 7-2. Alternative Evaluation for Screen Replacement (Project BLI-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	5						

7.2.2 Disinfection

7.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two fiber-reinforced plastic (FRP) tanks, three diaphragm pumps, two disinfectant rapid mix zones, and four induction mixers. There are two screens and each discharge into two disinfectant rapid mix zones in series. There are two induction mixers, one per disinfectant rapid mix zone in series, consisting of one low level mixer and one high level mixer. The sodium hypochlorite pumps discharge to a common header that splits to the two mixing zones and splits again to each induction mixer in that zone. The Basis of Design Report does not discuss sodium hypochlorite flow splitting. Flow splitting is not metered and there does not appear to be any basis for throttling the valves to individual induction mixers to achieve equal flow splitting. Table 7-3 provides an overview of the existing disinfection system at Belle Isle CSO facility.

Table 7-3. Overview of Existing Disinfection System at Belle Isle CSO Facility

Parameter	Value
Treatment Capacity (cfs)	33

Model Number/ hp / Manufacturer	SWC15XP / 15 hp / Water Champ

7.2.2.2 Identified Needs and Issues

The needs and issues identified for Belle Isle were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Belle Isle chemical feed system has the following issues:
 - The chemical piping is complex and congested. This is due to the available space being small for the three diaphragm-style pumps installed in a manufacturer's skid containing some potentially unnecessary pipe branches and components. Smaller footprint pumps and simplified piping could reduce complexity and congestion.
 - Chemical feed pumps are on large skids and removal of the skid would require significant pipe disassembly. A means of removing assemblies weighing more than 100 pounds is desired.

These issues are addressed in Replace Chemical Feed System (Project BLI-DIS-1) in the following bullets.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project BLI-DIS-2) in the following section.
- Complex recirculation pumps piping which makes it difficult to access pumps. This issue is addressed in Replace Chemical Recirculation System with Simplified System (Project BLI-DIS-3) below.

7.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project BLI-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities are included in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, BLI-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 7-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 was obtained from the replacement costs of the SRP.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 were estimated based on manufacturer pump rebuilds at an average cost of \$20,000 per year and GLWA onsite rebuilds at an average cost of \$12,000 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10 and routine maintenance. This frequency is based on GLWA's experience at Conner Creek.

Table 7-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 7-4. Alternative Evaluation for Replace Chemical Feed System (Project BLI-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 234,619	\$ 32,000	\$ 909,487	\$ 436,554	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3

	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BLI-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue included in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-Paced and TRC-Paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation for these alternatives is presented in Table 7-5. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be consistently met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 7-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project BLI-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Replace existing chemical feed control system utilizing current level of controls and	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Replace Chemical Recirculation System (Project BLI-DIS-3). The recirculation pumps' piping is unusually complex, which is readily apparent when compared to that at the Oakwood CSO facility. The area available for recirculation on the opposite side of the tanks from the feed pipes is small and the unnecessary complexity results in poor access to the pumps. The two alternatives are:

- 1) **Alternative 1: Do Nothing.** Maintain existing system.
- 2) **Alternative 2: Replace Chemical Recirculation System with Simplified System.** It is recommended that the complex recirculation pump and piping layout be replaced with a single pump per tank recirculation patterned after Oakwood (Figure 7-4).

Figure 7-4. Comparison of Complex Piping at Belle Isle (left) and Simplified Chemical Piping at Oakwood CSO Facility (right)

The alternative evaluation is presented in Table 7-6. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than Alternative 1 based on the improved O&M provided by simplified piping. The NPV/Benefit cost for Alternative 2 is \$67,500, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the ease of O&M with this alternative, Alternative 2 – Replace Chemical Recirculation System with Simplified System, is the recommended alternative.**

Table 7-6. Alternative Evaluation for Replace Chemical Recirculation System (Project BLI-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Maintain existing system	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Poor access to pumps.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Chemical Recirculation System with Simplified System	Health and Safety	3	3.22	\$ 217,000	\$ -	\$ 217,000	\$ 67,461	Not Applicable
	<i>Definition:</i>	Replace existing piping with straight-forward piping.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less pipe to maintain.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.3 Odor Control

7.2.3.1 Description of Existing System

The Belle Isle odor control system is a vertical flow, single dual-bed vertical carbon adsorber. The odor control fan pulls foul air from the screenings chamber, mixing chamber, and retention basin when liquid is detected in any of these areas. Carbon is replaced through the top and side access hatches on the vessel.

The system was installed in 2007. Overall, the system is in good condition. For a detailed condition assessment of individual odor control assets, see CS-299 Condition Assessment.

This odor control system operates under air permit requirements (Permit to Install No. 333-07). The emission limit is 0.0107 pounds per hour of hydrogen sulfide. At a design air flow of 8,800 cfm, this equates to approximately 0.23 ppm concentration of hydrogen sulfide. The carbon is tested for remaining bed life on a quarterly basis as required by the permit. Carbon was replaced in February 2019, which was the first time it was replaced since it was put into service.

Per GLWA, no odor complaints have been received for at least the past 3 years.

7.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- The odor control vessel has a dome top which increases the risk of slipping during carbon replacement.
- Accessing the top bed of the media for sampling is not easily performed. Jacobs investigated this issue further for this evaluation and the findings and recommendations are presented in the following paragraphs.

Quarterly carbon samples are taken from the top bed so that the final layer of carbon media can be analyzed to test for breakthrough. The final layer of carbon media is not accessible in the bottom bed. Accessing the top bed requires two operations staff to safely hold the ladder against the cylindrical vessel while a third staff members scales the ladder and opens the top hatch to collect the sample.

During meetings with O&M staff, Jacobs suggested that the discharged air from the vessel could be sampled and analyzed for breakthrough of H₂S. Sampling of discharged air is safer and less labor intensive than carbon media sampling. However, air sampling also requires the facility to be in operation during a wet weather event. Due to the multiple other duties of O&M staff during a wet weather event, GLWA decided to continue sampling the carbon media, which can be done during dry weather periods.

As an alternative to sampling carbon through the top access hatch, carbon may be sampled from one of the six sample ports on the side of the carbon vessel. Three ports are provided for each carbon bed. Carbon should be sampled from one of the two ports shown on Figure 7-5. These ports are located near the discharge end of each carbon bed. The lower port may be sampled from ground level. A grain thief is necessary to obtain a sample from the ports. A grain thief (see Figure 7-5, <https://www.globalgilson.com/sampling-probes>) is a device used for obtaining a grain sample from a silo and can be constructed from PVC or purchased from agricultural supply stores and other online sources. Carbon analysis is a common service provided by most activated carbon suppliers or can also be performed by many analytical laboratories.

Figure 7-5. Carbon Sample Ports (left) and Grain Thief (right)

7.2.3.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative

Access to Odor Control Vessel (Project BLI-OC-1). Staff indicated that the recent carbon replacement at the facility required constructing scaffolding to safely access the top of the carbon vessel for replacing the top carbon bed. The vessel has a dome top increasing the risk of slipping.

Jacobs evaluated two alternatives that would make accessing the top of the carbon vessel safer for both sampling and carbon replacement and compared it to the current approach. Alternatives include:

- 1) **Alternative 1: Erect scaffolding for Carbon Replacement.** The O&M staff currently erects a scaffolding when replacing the carbon. The carbon needs to be replaced about every 10 years.
- 2) **Alternative 2: Ladder and Railing System.** Figure 7-6. shows a ladder and railing alternative. A contractor would field install fiberglass clips and receptacles to the existing fiberglass tank to secure the ladder and railing. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps. The figure does not show a 6-in. toe rail, which is recommended, that should be installed at the bottom of the railing to help prevent a person's foot from slipping off the domed top along with tools and equipment.

Figure 7-6. Example of Ladder and Railing (figure is not Belle Isle's odor control system)

- 3) **Alternative 3 - Ladder, Platform and Railing System:** Figure 7-7 shows an example of a ladder, platform, and railing on a horizontal tank. The platform provides a more stable working surface than the domed top. The option is a safer option because the platform provides a flat surface on which to stand. A contractor would field install fiberglass clips and receptacles to the existing fiberglass tank to secure the ladder, platform, and railing. Installation of the platform and rail option is more expensive than the railing only option (Option 1) as a crane is necessary to remove the metal roof and lower the platform from above. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.

Figure 7-7. Example of Ladder, Platform and Railing (figure is not Belle Isle's odor control system)

The alternative evaluation for these alternatives is presented in Table 7-7. The sources of costs used in this evaluation are listed below:

- The O&M cost for Alternative 1 is based on \$15,000 for erecting scaffolding. Because the carbon is replaced once every 10 years, the annual O&M cost is assumed to be \$1,500.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Ladder and Railing System has a Total Benefit score 1.0 higher than Alternative 1 – Erecting Scaffolding due to the improved safety and the ease of O&M. Alternative 2 also has the lowest NPV/Benefit cost. **As such, Alternative 2 – Ladder and Railing System, is the recommended alternative.**

Table 7-7. Alternative Evaluation for Access to Odor Control Vessel (Project BLI-OC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	5						

7.2.4 Flushing and Dewatering

7.2.4.1 Description of Existing System

Dewatering System: After a wet weather event that fills the basin, the basin, screen channel, and mixing channels are dewatered by gravity back to the Belle Isle Pump Station, and subsequently pumped to the DRI and then to the WRRF.

Flushing System: Each basin contains a single flushing gate. After the basin is dewatered, the water in the flushing reservoirs (or NPW, if necessary) is used to flush the solids from the floor of the basins. The flushed solids flow by gravity to the Belle Isle Pump Station.

Table 7-8 provides an overview of the existing flushing and dewatering system at Belle Isle CSO facility.

Table 7-8. Overview of Existing Flushing and Dewatering System at Belle Isle CSO Facility

Parameter	Value
Total Basin Volume (MG)	0.3
Headworks and Basin Dewatering and Flushing System	- Each basin has one flushing gate - Flushed solids are routed by gravity to Belle Isle Pump Station

7.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids can accumulate in the corners of the mixing channels
- Local control of the valves in the two basin dewatering valve vaults requires confined space entry into the vaults. This issue is addressed in the I&C section (Section 7.2.7).

7.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing System in Mixing Channel (Project BLI-FD-1). Review of the 3-D scanning results for CS-299 showed that there was a build-up of solids in the corners of the mixing channels. A means to spray these locations is needed. There are two alternatives for addressing the solids buildup in the corners of the mixing channels. These alternatives include:

- Alternative 1: Do Nothing/ Manual Flushing Build-Up Solids.** Allow solids to build-up and manually flush once every 3 months. One of the disadvantages of this alternative is that the solids in the mixing channels that are not removed after draining the basin may affect subsequent disinfection.
- Alternative 2: Flushing System in Mixing Channel.** The recommended improvement includes mounting a 4-in. HDPE header along the perimeter of the mixing channel approximately 3 ft above adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B, for figures (Figure BLI-FD-1-ALT-2) showing conceptual layouts. The HDPE header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 0.75-in.-diameter) that create a water jet. The proposed hole spacing along the header is 18 to 24 in. A total flow rate of 250 gpm is required to adequately remove settled materials from the concrete shelf above the dry weather flow channel and

maintain adequate volume and velocity to carry materials into the dry weather flow channel following a CSO event.

Onsite NPW will be required. The final designer should confirm that the pressure in the existing water line is adequate (15 to 20 psi at the drilled hole) to meet the flushing requirements. The intent will be to use existing water pressure and not a booster pump. The 4-in. HDPE header should be connected to the interior NPW system piping. Following a wet-weather event, a motor operated solenoid/gate/ball control valve will be opened to charge the flushing header. The control strategy assumes that solenoid is activated for a set duration (minimum of 15 minutes) after the level sensors in the mixing channel record a water level rise above elevation 95.0 ft and subsequent water level drop.

A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying.

During initial operation, onsite staff should visually inspect the mixing channel area to confirm settled materials have been adequately removed and then adjust the control system timer to increase/decrease the flushing duration as needed until the system has been optimized. Provisions to flush the header pipe could be provided by adding another automatically operated valve at the terminal end of the header to open at the start of the flush event and flush any accumulated debris from the pipe. Integration with the facility's SCADA and LC) system is required to achieve this functionality. New electrical connections to the new control valve are also required (110 V).

The alternative evaluation for these alternatives is presented in Table 7-9. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M cost for Alternative 1 assumes two personnel for 4 hours each day for manually flushing the mixing channels every 3 months.
- The O&M cost for water usage is assumed to be the same for the two alternatives, and therefore, not included in the O&M costs.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 1 – Do Nothing/ Manual Flushing Build-Up Solids, has the lowest NPV/Benefit cost and is considered the Best Value Alternative. **As such, Alternative 1 – Do Nothing/ Manual Flushing Build-Up Solids is the recommended alternative.**

Table 7-9. Alternative Evaluation for Flushing System in Mixing Channel (Project BLI-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Manual Flushing Solids Build-Up	Health and Safety	2	2.22	\$ -	\$ 3,200	\$ 67,487	\$ 30,445	Best Value Alternative
	<i>Definition:</i>	Allow solids to build-up and manually flush.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Solids in the mixing channels that are not removed after draining the basin may affect subsequent event water quality.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing System in Mixing Channel	Health and Safety	4	3.50	\$ 151,000	\$ -	\$ 151,000	\$ 43,143	
	<i>Definition:</i>	Install a spray flushing system in each mixing channel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Solids are removed from the mixing channel after every storm.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased assets to maintain.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.5 HVAC

7.2.5.1 Description of Existing System

The Belle Isle facility consists of a headworks, chemical room, odor control room, electrical room, mechanical room, control room, sample room, and restrooms. The facility also includes an adjoining retention basin. Table 7-10 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, sanitary system, electric water heater, electric water cooler and emergency shower/eye washes. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 7.2.10.

Table 7-10. Major HVAC Equipment at Belle Isle CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	WEF-2 and 3	Wall Exhaust Fans	3,350 cfm
	MAU-1	Make-up Air Unit	6,700 cfm
Basin	REF-1 and 2	2 × Roof Exhaust Fans	6,500 cfm
Chemical Room	WSF-1	Wall Supply Fan	1,600 cfm
	IEF-1	Inline Exhaust Fan	1,600 cfm
	EUH-1 and 2	Electric Unit Heater	2,450 cfm 25 kW
Electrical Room	IEF-2	Exhaust Fan	1,000 cfm
	IEF-3	Exhaust Fan	3,700 cfm
	EUH-5	Electric Unit Heater	580 cfm 5 kW
	EUH-6	Electric Unit Heater	5 kW

Notes:

kW = kilowatt(s)

Table 7-11 provides a summary of the basis of design performance criteria for HVAC systems at Belle Isle and Table 7-12 provides the outdoor Basis of Design conditions.

Table 7-11. Belle Isle Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Headworks Area	Class I, Div 2, Group D (Per As-Built Drawings)	60	N/A	12 ACH (Occupied)
Mechanical Room, Electrical Room	Unclassified	60	104	1 ACH (Mechanical Room) 1 ACH (Electrical Room)
Odor Control Area	Class I, Div 2, Group D (Per Basis of Design)	72	75	6 ACH (Occupied) 2 ACH (Unoccupied)

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Sample Room, Men's and Women's Washrooms, Control Room	Unclassified	72 (Occupied), 60 (Unoccupied)	75 F Dry Bulb, 50% Relative Humidity	1 ACH (Office) 6 ACH (Other Areas)
Chemical Room	Class I, Div 2, Group D (Per Basis of Design)	60	100	6 ACH (Occupied) 2 ACH (Unoccupied)

Winter (Dry Bulb F)	Summer (Dry Bulb °F)	Summer (Wet Bulb °F)
3	91	73

7.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- MAU-1 provides inadequate heat for Headworks Area: It was noted by O&M staff that this unit does not provide enough heat in the winter. However, no frozen pipe issues were noted in this area.
- Corrosion of Unit Heaters (UH-1 to UH-6). It was noted that half of Trane UHXA unit heaters at the facility have been recently replaced by GLWA's HVAC contractor due to corroding of copper soldering in the unit.
- Frequent failures of DX cooling coil in AHU-1. It was reported in the meetings that the Trane AC unit fails every year.
- Chemical room unit heater and exhaust fan are difficult to access due to the tight conditions in the room and the poor accessibility.
- The backflow preventer occasionally sprays water in the sample room.
- Occasional low water pressure at the facility: See Site Section 7.2.8.2 for discussion of this issue.
- Difficultly accessing chemical room HVAC equipment for maintenance: GLWA's HVAC contractor confirmed that accessing exhaust fan and unit heater in the chemical room for maintenance is very difficult. Routine maintenance has required the erection of scaffolding.

During site investigations (June 2020) the following observations were noted:

- Both Trane UHXA unit heaters in the chemical room had been replaced by Indeeco Ultra-Safe EXP unit heaters.
- The door between the electrical room and the adjacent Corridor was held open with a rope.
- Explosion proof unit heaters were provided throughout the facility including in spaces without explosion proof electrical equipment and lighting fixtures such as the electrical room and chemical room.
- The Trane UHXA unit heater in the electrical room had been replaced with an Indeeco Ultra-Safe EXP unit heater.

- The supply and exhaust fans in the odor control area were observed to be not running.
- The supply and exhaust fans in the chemical room are very difficult to access for maintenance due to their locations. See Figure 7-8. below.

Figure 7-8. Chemical Room Supply and Exhaust Fans Located in Inaccessible Area

- The exhaust fans were observed to not be running in the Headworks Area.
- Opening the Basin access hatches did not start either of the Basin exhaust fans. The fans should start when the hatch is opened.

7.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project BLI-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) Alternative 1: Do Nothing/ Replace In-Kind.

- Replace MAU-1 in kind.

2) Alternative 2: HVAC Improvements including,

- Odor Control Area ventilation improvements
- Odor Control Area fan maintenance access
- Headworks ventilation

- Unit heater replacement
- Improved cooling for control room and sample room
- Improved access for chemical room HVAC equipment
- Water spray from backflow preventer

Each of the HVAC related improvements listed above are described further below:

Odor Control Area Ventilation Improvements. The 2003 Basis of Design report indicates that both the Chemical Room and the Odor Control Room were classified as Class I, Division 2 per NFPA 820; however, all other spaces aside from the Headworks Area and Basin were indicated as unclassified. Jacobs notes that chemical rooms are not Class I, Division 2 spaces. Rather, they are unclassified spaces, provided they are physically separated from classified spaces. The Chemical Room therefore does not require explosion-proof equipment such as the explosion-proof unit heaters currently installed in this space.

Per NFPA 820-2003, which was in effect when the facility was designed, the Odor Control Room is considered a Class I, Division 2 space if it is not continuously ventilated at 6 air changes per hour (ACH). However, the exhaust and supply fans in the odor control area were sized based on 6 ACH, which would make the area unclassified. Jacobs notes that the fans must run continuously and ventilation monitoring on both the supply and exhaust fan is required to detect no airflow. Ventilation failure and combustible gas in excess of 10 percent of the Lower Explosive Limit needs to be alarmed with visual and audible alarms at the entrance to the odor control area as well as inside the space.

It is recommended that the Odor Control Room be made unclassified by meeting the requirements noted above. Continuous ventilation of the odor control area and providing slight negative pressurization with respect to the atmosphere should have the added benefit of reducing H₂S levels in the electrical room, which was likely the cause of the need to replace the Trane UHXA unit heaters.

It should be noted that although it is not a code requirement, current best practice is to physically separate electrical rooms from spaces with corrosive conditions (e.g., the Odor Control Room) and to positively pressurize the space with respect to these areas. If the Odor Control Room is provided with negative pressurization with respect to adjacent spaces this most likely will not be necessary but if corrosion of the equipment in the electrical room becomes an issue it should be considered.

Odor Control Area Fan Maintenance Access. It is difficult to access WSF-2 and WEF-1 for maintenance purposes due to their locations high in the space and the proximity of conduit and piping restricting ladder access from below (Figure 7-9).

Figure 7-9. Odor Control Room Exhaust (left) and Supply (right) Fan Poorly Accessible

Access to WEF-1 could be provided by installing a platform which would be accessed from the landing outside of mechanical room on the second floor. This would effectively be an extension of the existing landing. WSF-1 could be provided with a platform with ladder access. This project should be coordinated with the Improved Access to Odor Control Vessel (Project BLI-OC-1) project.

Headworks Ventilation. Per the electrical record drawings, the Headworks area is electrically a Class I, Division 2 space which requires ventilation at a continuous rate of 12 ACH. Neither the odor control unit (which exhausts air from the Basin and Headworks Area), nor the Headworks Area exhaust fans were observed to be running during the site visit. This means the space is effectively a Class I, Division 1 environment containing equipment only rated for a Class I, Division 2 environment. It was also noted that Headworks Area exhaust fan WEF-3 is located only approximately 3 ft from odor control area supply fan WSF-2 (see excerpt from HVAC drawings below). When both fans are running, air being exhausted from the Headworks Area will be introduced into the odor control area by WSF-2 (Figure 7-10). This could have contributed to the corrosion which lead to the need to replace the Trane UHXA unit heaters.

Figure 7-10. Short-Circuiting of Airstreams Between WEF-3 and WSF-2

In addition to issues with short-circuiting of the air streams between WEF-3 and WSF-2, MAU-1 has a duct which runs from the mechanical room through the odor control area to the headworks area (Figure 7-11). The ductwork between the classified Headworks Area and the unclassified mechanical room is a breach in physical separation as defined by NFPA 820 and effectively classifies the entire building with the same classification as the Headworks Area.

Figure 7-11. Ductwork Passing Between Classified and Unclassified Areas

It is recommended that MAU-1 be removed and replaced by either a MAU located at the ground level near the Headworks Area or a supply fan with the same capacity as MAU-1 and explosion proof unit heaters. For cost estimating purposes, a new supply fan and unit heaters are assumed. Locating the supply fans or MAU on the North side of the Headworks Area and relocating WEF-3 to the South side would have the benefit of eliminating the short-circuiting currently occurring between WEF-3 in the Headworks Area and WEF-2 in the odor control area.

Increased MAU-1 Heating Capacity (if necessary). MAU-1 serves the Headworks. It was noted by O&M staff that this unit does not provide enough heat in the winter. The basis of design dry bulb temperature for the Headworks area is 60°F, so it is possible that this area could be perceived as being cold in the winter. No pipes have frozen in the past in this area. If additional heating is desired in this space, a unit with increased heating capacity should be provided with the new MAU described in the project above.

Unit Heater Replacement. The Trane UHXA unit heaters at the facility have an aluminum-finned tubular steel heat exchanger which is directly exposed to the air stream when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail, they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating that has passed the ASTM International Method B117 salt-spray test. The Indeeco units are a good selection for the electrical room and odor control area. If the odor control area is unclassified, they are not required to be explosion-proof. Based on the recommendation to replace the units when they fail, their cost is not included in the capital cost estimate, rather, they are in the SRP.

The Indeeco units currently installed in the chemical room should last longer than the Trane UHXA units which they replaced; however, even 316 stainless steel is also susceptible to corrosion by sodium hypochlorite.

Improved Cooling for Control Room and Sample Room. GLWA's HVAC contractor noted that while there have been mechanical failures in AHU-1 in the past, the failures were not out of the ordinary in terms of frequency or severity and have been reportedly rectified.

It is likely that AHU-1 could appear to be under-performing in terms of cooling due to the fact that when the space is unoccupied, the setpoint is controlled to increase to 85°F. Operators visit the facility infrequently and in the short amount of time they are at the facility the temperature in the spaces served by AHU-1 (i.e., the sample room, control room, men's and women's restrooms, and corridor) may not reach the Basis of Design temperature of 72°F.

In order to improve operator comfort when the facility is occupied it is recommended that split direct expansion (DX) units be installed in the sample room and control room. The evaporator units in the split DX systems could be configured to discharge in locations where operators are likely to be located and would provide a faster response to occupancy than the current system configuration. The proposed split DX units would be provided in addition to the existing AHU-1 cooling coil and would be provided with their own thermostat.

Improved Access for Chemical Room HVAC Equipment. GLWA's HVAC contractor noted the need to erect scaffolding to perform maintenance on the unit heater and exhaust fan in the chemical room. Jacobs recommends either (1) installing a platform with ladder to allow for maintenance on the exhaust fan and relocating the unit heater to an area where ladder access is possible, or (2) evaluating and possibly repositioning the supply and exhaust fans closer to the floor when the chemical feed system is re-designed in the future (as described in the CS-299 Disinfection technical memorandum).

Water spray from backflow preventer. During the site visit water was noted on the floor near the backflow preventer with no drain near the unit (Figure 7-12). Jacobs recommends the installation of

an airgap fitting with hose attachment and running the hose to the nearest drain. This should address the water spray.

Figure 7-12. Water Spray Near Backflow Preventer

The alternative evaluation is presented in Table 7-13. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for MAU-1 in Alternative 1 was obtained from the SRP. It should be noted, however, that replacement of the MAU in its current location would likely not be code compliant.
- The O&M costs for Alternative 1 include scaffolding costs (to perform maintenance on the unit heater and exhaust fan in the chemical room).
- The capital costs for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 1 is the Best Value Alternative. However, replacement of the MAU in its current location would likely not be code compliant. In addition, Alternative 2 has a total benefit score about 1.0 higher than the Alternative 1 based on the improved health and safety and improved O&M. **As such, Alternative 2 - HVAC Improvements is the recommended alternative.**

Table 7-13. Alternative Evaluation for HVAC Improvements (Project BLI-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	2	2.50	\$ 63,500	\$ 2,000	\$ 99,591	\$ 39,836	Best Value Alternative
	<i>Definition:</i>	No improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lack of code compliance, difficult, less safe, and more costly maintenance, corrosive gases entering building, and control room discomfort.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	4	3.50	\$ 293,000	\$ -	\$ 293,000	\$ 83,714	
	<i>Definition:</i>	Addition of Odor Control area ventilation monitoring to meet code requirements, replacement of MAU-1 with new system, improved fan access for maintenance, and supplemental air conditioning.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, easier and safer maintenance, more comfortable control room conditions.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.6 Electrical

7.2.6.1 Description of Existing System

The Belle Isle electrical system consists of one DTE utility feed from a 1,000 kVA, 480 V, 3-phase outdoor transformer (primary metering) and one diesel generator feed from a 750 kilowatts (kW), 480 V, 3-phase stationary generator. The feeds are connected to a 1,200 A switchboard with electrically operated breakers and automatic source transfer controls. The switchboard then feeds a 1,200 A motor control center (MCC). The MCC then feeds the various pumps, valves, motors, transformers, panels, etc. at the facility. The Belle Isle Pump Station is fed from the CSO facility MCC; however, it is not included in this facility assessment, per the CS-299 Scope of Work. Table 7-14 provides a summary of the major electrical equipment for this facility.

Table 7-14. Major Electrical Equipment at Belle Isle

Location	Major Electrical Equipment	Description
Electrical Room	Main Switchboard/ATS	1,200 A, 480/277 V, 3-Phase
Outdoors	Generator (Diesel)	750 kW, 480 V, 3-Phase
Electrical Room	MCC	1,200 A, 480/277 V, 3-Phase

7.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

7.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project BLI-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting, however it will be less safe when operating at night and when accessing area downstream of screens.
- 2) **Alternative 2: Electrical Improvements.** Add lighting at the following location (and shown on the electrical drawings - Figure BLI-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin – Add additional external lighting on top and the riverside of the basin. Lighting foot-candles will meet the requirements of the local outdoor lighting ordinances.

The alternative evaluation is presented in Table 7-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting. The NPV/Benefit cost for Alternative 2 is \$16,500, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 7-15. Alternative Evaluation for Electrical Improvements (Project BLI-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 58,000	\$ -	\$ 58,000	\$ 16,571	Not Applicable
	<i>Definition:</i>	Add additional external lighting on top and the riverside of the basin.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.7 I&C

7.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2007 under PC-753. This project upgraded the existing Belle Isle Pump Station facility to include the new CSO basin facility. In 2014 under PC-773D, the Ovation system controllers and software were upgraded to version O.V.3.5.0.

The facility's Ovation network currently has only one primary network switch. The switch is connected to the GLWA AT&T wide area network via the system's router. The system has one database server and one operator workstation located in the control room. The system has a pair of Ovation controllers that provide the facility with redundant local controls and I/O capabilities. All network connections in the Belle Isle facility are via copper Ethernet cables. The controllers are connected to the network via a single-homed connection, which means each controller has only one connection to the network switch. Since there is only one network switch, the primary switch is a single point of failure for the overall system. The current system is equipped with a back-up radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 7-16 summarizes the level sensors and flow meters at the Belle Isle CSO Facility used to monitor flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 7-16. Summary of Flow Meters and Level Sensors at Belle Isle CSO Facility

7.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets:

- GLWA requested to have the ability to control the Belle Isle CSO Facility from Conner Creek to improve operational efficiency during CSO events.
- GLWA requested that Jacobs investigate the potential removal of gas monitors in the basins for Belle Isle to reduce instrumentation maintenance requirements.
- GLWA requested process cameras at select locations to improve monitoring of the facility during wet weather operation.
- Local control of the valves in the two basin dewatering valve vaults requires confined space entry into the vaults.
- Generator and ATS controls do not adequately report alarm signals into Ovation and are becoming less reliable. This issue is being addressed in an on-going project and is therefore not included in the capital improvement projects for CS-299.
- Update Ovation control system to the latest version and increased monitoring capabilities.
- Control system network lacks redundancy.

7.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project BLI-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, all of the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into multiple delivery projects, if needed. There are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements including,**

- Provide remote operation of Belle Isle CSO Facility from Conner Creek CSO Facility
- Investigate need for gas monitoring in CSO basins
- Provide process cameras at select locations
- Provide local control capabilities of actuators in valve vaults

Each of the I&C related improvements listed above is described further below:

Provide remote operation of Belle Isle CSO Facility from Conner Creek CSO Facility. GLWA requested to have the ability to control the Belle Isle CSO Facility from Conner Creek to improve operational efficiency during CSO events. The physical infrastructure is in place to allow this to happen. It is recommended that GLWA investigate the programming through SCADA to determine if the code has already been written and activate if that is the case. If the existing programming in SCADA does not contain code for remote control of Belle Isle from Conner Creek, provide additional programming for this functionality.

Investigate need for gas monitoring in CSO basins. Eliminate gas monitoring equipment in accordance with Section 5.4.7.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Provide local control for valves in valve vaults above ground (outside of vault). Local control of the valves requires confined space entry. Providing controls above ground, outside of the valve vault would improve safety, when local control of the valves may be needed.

The alternative evaluation is presented in Table 7-17. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M costs for Alternative 1 assume that the lack of remote control of the Belle Isle facility requires additional operator time every wet weather event.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- O&M costs for Alternative 2 include an estimated annual cost for maintenance of the proposed cameras.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative because the NPV/Benefit cost of Alternative 1 is about \$7,000 lower than that of Alternative 2. The total benefit score for Alternative 2 is 1.3 higher than Alternative 1, due to improved health and safety, and ease of O&M. Based on the higher total benefit score and the small difference in NPV/Benefit cost, **Alternative 2 - I&C Improvements is the recommended alternative.**

Control System Upgrade (Project BLI-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2. As part of this project, it is recommended to increase network switch redundancy. Adding a back-up network switch within the system will eliminate the single point of failure of the primary network switch. Once the back-up network switch is added, the connections to the network equipment and Ovation controllers will need to be converted to a dual-home configuration instead of single-home connections. This will provide full redundancy and should one of the networks fail, the second network will remain available for monitoring and control.

Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 7-18 provides the summary of the **Control System Upgrade, which is the recommended alternative.**

Table 7-17. Alternative Evaluation for I&C Improvements (Project BLI-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ 4,000	\$ 84,359	\$ 33,743	Best Value Alternative
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Unexpected conditions may occur in the Headworks	Component Performance	3						
	<i>Comments:</i>	Annual O&M without remote control of basin: 10 events; 4 hrs per event; \$100/hr	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	5	3.78	\$ 112,000	\$ 2,000	\$ 154,179	\$ 40,752	
	<i>Definition:</i>	Provide local control of valves without entering valve vault, install cameras for monitoring of process areas, and eliminate gas monitoring in CSO basins.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance (with reduction of gas monitoring), and more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance (with addition of cameras)	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Table 7-18. Alternative Evaluation for Control System Upgrade (Project BLI-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 922,000	\$ -	\$ 922,000	\$ 307,333	Best Value Alternative
	<i>Definition:</i>	Upgrade control system to latest version of Ovation.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Allows for use of high performance graphics and provides other benefits.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

7.2.8 Site

7.2.8.1 Description of Existing Site

The Belle Isle CSO Facility was constructed in 2009. The site includes the CSO facility and a sanitary pump station used to pump sanitary and retained storm flows from Belle Isle to the DRI on the west side of the Detroit River. The total area of the site is approximately 0.85 acres and includes an access road, parking area and fencing. The security fencing is 6-ft tall. There is a 24-ft wide sliding gate at the southern corner of the fenced-in area, as well as multiple smaller swing gates in other parts of the fence.

Site access/egress is by access road off of Sunset Drive. A parking area is located along the west side of the site to accommodate parking for O&M personnel and visitors. The access road and parking area consist of concrete pavement. The reinforced concrete sidewalk is 5 in. thick with 2 in. of aggregate base course. The rest of the reinforced concrete pavement on site is 10 in. thick with 9 in. of aggregate base course.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

7.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Inadequate space or turning radius inside the site for the sodium hypochlorite tanker trucks to maneuver through the site.
- Water ponding near the entrance gates.
- GLWA Operations has experienced issues at the basin roof drain scupper outlets as they get plugged by leaves and debris resulting in ponding on the basin surface.
- Investigate occasional low water pressure. GLWA has experienced low pressure in the incoming potable water line to the Belle Isle CSO facility in the past. The watermain servicing the facility is 6-in.-diameter. Based on discussions with GLWA after the Needs Assessment meeting, GLWA staff believes the pressure issues may have been related to Detroit Water and Sewerage Department closing valves and changing flow paths during their operation of the system (now done by the State of Michigan). This may have resolved the issue. Pressure monitoring of the water pressure at the fire hydrant outside the facility could be performed over an extended period of time (i.e., a few months) to better determine the timing and magnitude of the issue, if this is still an issue in the future.
- Seal concrete pavement joints of service drive and parking area to ensure serviceability. This could be considered a preventative maintenance item; however, for this evaluation, costs have been included in the Site capital improvements to address any concrete pavement joints or other repairs.

7.2.8.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project BLI-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Tanker Truck Access
 - Address Ponding Near Service Drive Entrance
 - Improve Basin Surface Drainage

Each of the site related improvements listed above are described further below:

Tanker Truck Access: The sodium hypochlorite fill station is located on the south side of the facility. Tanker trucks must access this location several times a year for hypochlorite delivery. Currently, the trucks pull up on a temporary unpaved access drive next to the City's barricade storage yard outside of the fence line, and then run a hose through a manway gate to the fill station to offload the hypochlorite. There is not adequate space or road turning radius inside the site for the tanker trucks to maneuver through the site. Trucks accessing the truck fill station outside the fence is not ideal as trucks could get stuck in the soft grade while pulling up and turning on the site.

It is recommended that the concrete pavement be extended parallel to the existing drive from the entrance service drive to the truck fill location, and then extended southward with adequate paved area to provide adequate turning radii for the tanker truck to turn to the south and back up to the manway gate at the point of the truck fill (see Figure BLI-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B).

Address Ponding Near Service Drive Entrance: A low point in the existing site grading exists on the north side of the service drive near the entrance gate to the facility. This is an area where water encroaches on the service drive frequently and can be a nuisance, particularly in winter months when icing on the service drive is a concern. It is recommended that a catch basin be installed at this location and connected to the existing storm sewer near this low point.

Improve Basin Surface Drainage: The basin roof is sloped from south to north with drain scuppers located through a parapet wall that allow drainage through the wall to downspouts. GLWA Operations has experienced issues at the scupper outlets as they get plugged by leaves and debris resulting in ponding on the basin surface.

One alternative could be to remove the trees near the basin and replace them with a lower growing tree or shrub. Another alternative could be that the sizes and number of scuppers be evaluated, and appropriate modification be made to the scuppers to prevent leaves and debris from blocking the scupper outlets. Coring holes directly into the basin roof to provide additional drainage relief may also be considered as an alternative to work along with the existing scupper system.

The alternative evaluation is presented in Table 7-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than Alternative 1 based on the improved health and safety and improved O&M provided by the various site improvements. The NPV/Benefit cost for Alternative 2 is \$63,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 7-19. Alternative Evaluation for Site Improvements (Project BLI-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Maintain current operation for hypo deliveries and do not address ponding.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Trucks could get stuck in the soft grade while accessing the site & safety issue with ponding water.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 220,000	\$ -	\$ 220,000	\$ 62,857	Not Applicable
	<i>Definition:</i>	Improved tanker truck access, address ponding near service drive entrance, and improve basin surface drainage.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved maneuverability and safety during hypo deliveries & improved safety for accessing facility.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.9 Architectural

7.2.9.1 Description of Existing Facilities

The Belle Isle CSO Facility includes the CSO facility and a sanitary pump station used to pump Belle Isle sanitary flows to DRI on the west side of the river. The treatment facility consists of a chemical room, odor control room, utility support (electrical and mechanical), control room, sampler room, screen room and other miscellaneous rooms. The facility also includes an adjoining retention basin.

7.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 7-20. As such, the roof should be replaced in-kind and the costs and schedule for roof replacement will come from the SRP.

Table 7-20. 60-Year Life Cycle Cost Evaluation of Shingled vs. Metal Roof for Belle Isle Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$70,000	\$233,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life Cycle Cost (NPV) Discounted at 2.4%	\$190,000	\$233,000

^a Based on 4,650 ft² roof area; \$15 ft² for shingle roof and \$50/ft² for metal roof.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because the items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

7.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (BLI-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control /expansion wall joints
 - Remove and replace isolation /cove joint sealant and around building perimeter
 - Clean concrete bollards, patch, prepare surface and coat
 - Repoint mortar joints
 - Remove damaged coating, prepare surface, patch and apply coating to coping.

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure BLI-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (BLI-DIS-1).

The alternative evaluation is presented in Table 7-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 7-21. Alternative Evaluation for Architectural Rehabilitation (Project BLI-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 243,000	\$ -	\$ 243,000	\$ 78,387	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

7.2.10 Safety

7.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

7.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 7-22. The capital improvement project to address these issues is included in the table.

Table 7-22. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Chemical Room	Top and mid-rail fall protection needed at ladder access at top of tanks	Add swing gate (original recommendation was to add chain; however, this is no longer current GLWA practice)	Safety Improvements (Project BLI-SAFE-1)
Chemical Room	Emergency eyewash/shower is at different level from tank and pumps and it is partially obstructed by door	Relocate eyewash/shower	Safety Improvements (Project BLI-SAFE-1)
Odor Control Room	No illuminated exit signs	Add or replace exit signs	Exit Sign Improvements ^a
Odor Control Room	Concrete pad creates uneven exit access to exterior door	Remove section of concrete pad	Safety Improvements (Project BLI-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project BLI-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

7.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section.

Safety Improvements (Project BLI-SAFE-1). This project should address the safety issues identified above. These issues include:

- Add swing gate to access top of tanks in the chemical room
- Replace eyewash/shower in the chemical room
- Remove section of concrete pad in the odor control room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 7-23 shows the one alternative.

Table 7-23. Alternative Evaluation for Safety Improvements (Project BLI-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 82,000	\$ -	\$ 82,000	\$ 21,674	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, eye wash and exit signage.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at the Belle Isle CSO Facility.

7.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Belle Isle CSO facility, Table 7-24 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 7-24, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 7-24. Listing of Asset Condition Assessments for Belle Isle Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

UPS	2	2	0	100%
VALVE	21	19	2	100%
WATERHTR	1	1	0	100%

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable gas detector and was not assessed.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Belle Isle Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

7.3 Capital Planning for Belle Isle CSO Facility

7.3.1 Summary of Capital Improvement Plan Projects

Table 7-25 provides a summary of the recommended CIP projects and associated capital costs for the Belle Isle CSO facility based on the alternative evaluations conducted for this facility.

Table 7-25. Summary of Recommended Projects at Belle Isle CSO Facility

Project No.	Alternative	Description	Total Project Cost
BLI-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 274,000
BLI-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
BLI-DIS-3	2	Replace Chemical Recirculation System with Simplified System	\$ 217,000
BLI-OC-1	2	Ladder and Railing System	\$ 41,000
BLI-HVAC-1	2	HVAC Improvements	\$ 293,000
BLI-ELEC-1	2	Electrical Improvements	\$ 58,000
BLI-I&C-1	2	I&C Improvements	\$ 112,000
BLI-I&C-2	1	Control System Upgrade	\$ 922,000
BLI-SITE-1	2	Site Improvements	\$ 220,000
BLI-ARCH-1	2	Architectural Rehabilitation	\$ 243,000
BLI-SAFE-1	1	Safety Improvements	\$ 82,000

7.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 7-26. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 7-26. Capital Improvement Plan Projects for Belle Isle CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
BLI-1 Disinfection System Improvements	\$752,000	2028 <i>Timing based on asset condition</i>	BLI-DIS-1	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 274,000
			BLI-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 7-27 and Table 7-28 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 7-27 indicates that BLI-DIS-1 project has 13 assets that has an average condition score of 1.54 and an average replacement date of 2029. This information was used to propose a scheduled construction completion date of 2028.

Table 7-27. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BLI-DIS-1	13	1.52	1.54	2.79	12	2029	\$ 234,619
BLI-HVAC-1	1	1.29	1.50	2.25	20	2034	\$ 63,500
BLI-SCR-1	1	2.00	1.70	3.70	30	2041	\$ 489,400

Table 7-28. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BLI-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

BLI-SCR-1	1	2.00	5.00	7.00	30	N/A	\$ 489,400

7.3.3 20-Year Capital Outlay Plan

Table 7-29 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 7-29. 20-Year Capital Outlay Plan for Belle Isle CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 44,000	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 19,500	\$ -	\$ -	\$ 14,500	\$ 10,000	\$ -

- Notes:
- Explanation of large capital outlays in first two years:
- Screening System: Screen in Basin 2 was out of service at the time of the Condition Assessment for major repair and received a score of 5. It has since been returned to service.

8. Connor Creek CSO Control Facility

8.1 Facility Description and Future Capacity Considerations

8.1.1 General Facility Description

The Connor Creek CSO Facility is an RTB with 30 MG of storage and a treatment capacity of 13,963 cfs. It was constructed in 2005. The facility consists of a headworks, chemical room, chemical storage area (outdoor), utility support (electrical, transformer and mechanical rooms), control room, sample room, hydraulic room, office space on the second floor, and other miscellaneous rooms.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

8.1.2 Future Capacity Considerations

There were no future capacity considerations identified at the time of this report.

8.2 Facility Assessment

8.2.1 Screening

8.2.1.1 Description of Existing System

The Connor Creek CSO Facility has 10 catenary bar screens that were installed in 2005. Channels 1-3 were originally designed to be always open (i.e., there are no influent slide gates upstream of these screens). Channels 4-10 have motorized double leaf slide type influent gates that were originally designed to open sequentially, first as a set of two (Numbers 4 and 6), and then as a final set of all remaining gates, based on increasing influent flow. During a large wet weather event in 2016, the gates did not open because there was no remote control, GLWA staff could not get to the basin, and the local area flooded. GLWA Operations decided to leave them open until all SCADA / controls can be restored for the facility.

Screenings are discharged onto one of two conveyor belts which transfer the screenings to a dumpster. One belt is provided for Bar Screens 1 through 5 and another belt is provided for Bar Screens 6 through 10. The screenings are disposed of in a landfill.

Table 8-1 provides an overview of the existing screening system at Connor Creek CSO facility.

Table 8-1. Overview of Existing Screening System at Connor Creek CSO Facility

Parameter	Value
Treatment Capacity (cfs)	13,963
No. of Screens	10
Manufacturer	US Filter
Screen Type	Catenary Bar Screen
Opening Size	1.5-in. slot
Depth or Length / Width	29 ft 8.5 in / 17 ft 0 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

8.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Investigate conveyor belt improvements to address belt alignment issues and to address occasional buildup of screenings at start of the conveyor belt incline section.

Jacobs further investigated this issue with Custom Conveyor Corporation (the original belt manufacturer). It should be noted that Custom Conveyor will conduct a site investigation at a later date during CS-299 to assess the conveyor issues and provide recommendations.

Based on initial conversations, potential recommendations to address belt alignment issues include tightening the belt tension, installing training idlers, and replacing the belt. Tightening the belt tension by adjusting the tail pulley could prevent the belt from becoming misaligned. Installing training idlers approximately every 50-ft on the carry side of the belt can prevent the belt from walking off to the side. Over time, the belt may become stretched and exceed the ability of the tail pulley to provide further tension. The belt may also reach the end of its service life. In either case, the belt may need to be replaced.

Cleats may be recommended to prevent buildup of screenings at the start of the incline. Cleats prevent screenings from sliding down the belt. Cleats may be bolted onto existing belts. Cleats requires replacing the wiper used to clean the screens with a belt thumper. The belt thumper is slave driven off the discharge pulley.

No capital improvement costs have been provided to address this issue.

- GLWA O&M personnel requested improvements to access for screen maintenance, including for wear shoes and motor and gearbox. The motor and gearbox extend over the screenings channel and are difficult to reach from the walkway next to the screen. Currently, maintenance staff use a man-basket connected to the overhead crane to access the motor.

Jacobs further investigated this issue. One option would be to construct a walkway to provide better access; however, this will likely be a costly option. This issue has been added to the list of issues to be evaluated by E&I (original screen manufacturer) during their upcoming OEM screen assessment to determine if they have a better option. The results of E&I's evaluation will help determine the scope of any improvement.

During Jacobs safety inspection under CS-299, the following issue was identified in the Headworks Building:

- Eliminate low headspace between screenings dumpsters. During Jacobs Safety Inspection in January 2020, it was noted that the support beams for the screenings conveyor create a safety hazard for staff walking through the building due to their relatively low height. These beams support the head pulleys and discharge end of the screenings conveyors.

Jacobs contacted the original conveyor manufacturer (Custom Conveyor) to evaluate options for resolving this issue. Figure 8-1 shows a recommended modification that will eliminate the overhead safety concern. It involves providing a new drive-end conveyor support for each conveyor and relocating the drive motor. This is an on-going project being completed under a JOC.

8.2.1.3 Description and Evaluation of Alternatives

The issues above are either on-going or they do not require capital improvement at this time. As such, there are no alternatives identified as screening capital improvement "needs".

Figure 8-1. Conveyor Modifications to Improve Access through Headworks Building

8.2.2 Disinfection

8.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of four outdoor insulated rubber lined steel tanks, 10 constant speed magnetic drive centrifugal pumps, 10 disinfectant rapid mix zones, and 60 induction mixers. There are 10 screens and there is one disinfectant rapid mix zone immediately downstream of each screen. There is a diffuser at floor level immediately downstream of each screen to allow feeding sodium hypochlorite before the water level reaches the low-level induction mixers and to continue to provide disinfectant near floor level throughout an event. There are six induction mixers per disinfectant rapid mix zone consisting of two low-level mixers, two mid-level mixers, and two high-level mixers. Each sodium hypochlorite pump is paired to one disinfectant rapid mix zone. However, there is a valved crossover from each pump to one other pump. This provides less redundancy than a spare pump that could serve all disinfectant rapid mix zones. The sodium hypochlorite pumps each discharge to a manifold feeding the diffuser and 6 induction mixers at their paired rapid mix zone. There is a flow meter to the diffuser and each pair of low-level, mid-level, and high-level induction mixers. Flow splitting within each pair of mixers at a given level is assumed equal based on symmetry.

Table 8-2 provides an overview of the existing disinfection system at Connor Creek CSO facility and the disinfection process flow diagram is included in Volume 6 – Appendices, Appendix G.

Table 8-2. Overview of Existing Disinfection System at Connor Creek CSO Facility

Parameter	Value
Treatment Capacity (cfs)	13,262
Design Feed Strength (% hypochlorite)	10
Max. Dosage at Design Flow (mg/L Cl ₂)	25
Disinfection Contact Time (min)	5
Storage Tanks	
Number	4
Volume of Each Tank (gal)	95,000
Type	Rubber-lined steel
Pumps	
Number	10
Capacity (gpm)	197
Type	Centrifugal, magnetic drive
Mixers	
Number / Type	60 / Chemical Induction mixers
Model Number/ hp / Manufacturer	SWC20XP / 20 hp / Water Champ

8.2.2.2 Identified Needs and Issues

The needs and issues identified for Connor Creek were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Connor Creek chemical feed system has the following issues:
 - The back-pressure valves controlling the chemical feed split between the three pairs of induction mixers and the diffuser at each disinfectant rapid mix zone are not functioning properly. Also, one

back pressure valve serves each pair of mixers at a given level. Therefore, flow splitting between each pair of mixers is assumed equal based on symmetry alone.

- The flow meters are in need of replacement due to age and some are showing significant signs of corrosion. Also, the vertical downflow orientation is poor as there is the potential for a non-full pipe.
- Similar to other facilities, it is desired to standardize on a flow splitting regime that considers such attributes as simplicity, reliability, and functionality.
- Currently, a hose must be moved and connected to each pump suction pipe to flush the hypochlorite solution from the feed system with NPW. A hard-piped flushing water connection is desired so that flushing could be accomplished by opening a valve to each pump.
- The pump area is located down four steps and there is no dedicated means to lower or lift the pumps and motors to or from this area. A mechanical means of getting pumps in and out of the room is desired.

These issues are addressed in Replace Chemical Feed System (Project CON-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project CON-DIS-2) below.
- There are 60 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project CON-DIS-3).
- Heat tracing on the outside chemical pipes occasionally fails putting the piping at risk of failing if it freezes. In fact, piping in this outdoor area for the eye wash / shower stations has previously frozen and ruptured. The heat tracing and insulation also hinders access to detect and replace leaking fittings and pipes. This issue is addressed in Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4).

8.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project CON-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, CON-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to Conner Creek feed system:

- For cost estimating purposes, water piping and valving to each feed pump was assumed to allow water flushing for the entire chemical feed system from the feed pumps to the mixers.
- For cost estimating purposes, a mast type jib crane (also referred to as a base mounted jib crane – see Figure 8-2 for an example) for moving the pumps and motors up and down the flight of stairs. The base could be located approximately 4 ft from the bottom of the stairway so as to maintain sufficient egress to and from the stairway and to provide a set down area for the pump or motor. The beam would cantilever from the base over the stairway and the upper landing. An electric hoist and trolley could then be used to pick the pump or motor, raise it, convey it over the stairway, and set it down on the upper level. From there, a cart could be used to get the pump or motor out the door. This is the recommended alternative and was used for budgeting.

Figure 8-2. Example of Mast-Type Jib Crane

The alternative evaluation for these alternatives is presented in Table 8-3. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 8-3 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 8-3. Alternative Evaluation for Replace Chemical Feed System (Project CON-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System in-kind	Health and Safety	3	2.08	\$ 2,919,000	\$ -	\$ 2,919,000	\$ 1,401,120	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with feeding too much chemical. System is unique to Conner Creek.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 5,409,000	\$ 109,670	\$ 7,721,900	\$ 2,144,972	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per disinfection channel. Utilize hose pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	LOTS of pumps and valves, allows for an installed redundant pump but manual switchover.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 2,300,000	\$ 7,000	\$ 2,447,627	\$ 679,897	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps connected to all disinfection channels. Utilize centrifugal pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily utilized.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each disinfection channel.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project CON-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 8-4. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 8-4. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project CON-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 156,000	\$ 4,860	\$ 258,496	\$ 74,926	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixer (Project CON-DIS-3). Plant personnel report that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. These issues are exacerbated by having 60 induction mixers at Conner Creek, which is the highest of the nine CSO facilities. A reduction in the number of mixers would reduce maintenance and the associated expense proportionate to the reduction. It would also reduce the complexity for equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4). The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** Computation fluid dynamic (CFD) modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from six to three per channel). This needs to be confirmed by collection system modeling performed by others.
- 3) **Alternative 3. Install Vertical Shaft Mixers.** This alternative would replace the existing chemical induction mixers with new vertical shaft mixers. For Conner Creek, two mixers would be provided per channel.

The alternative evaluation is presented in Table 8-5. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$18,000 per mixer.
- The capital cost for Alternative 3 (vertical shaft mixers) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 (vertical shaft mixers) are based on expected maintenance costs, including changing oil, greasing bearings, periodic rag removal from the shaft and servicing the steady bearing.

As shown in Table 8-5, Alternative 2 has a Total Benefit score about 0.4 higher than Alternative 1 because of the improved ease of maintaining fewer mixers. Alternative 3 has a Total Benefit score slightly higher than Alternative 2 based on the anticipated improved performance of the vertical mixers and improved ease of maintenance, since the mechanical portion of above the water surface. **Alternative 2, has the lowest NPV/Benefit cost and therefore, is the recommended alternative.**

It should be noted that the cost of the reduced mixers is not a new capital cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection

performance can be achieved, the vertical mixer alternative should be further explored, possibly through the pilot testing of this technology in one of the channels at Baby Creek or Conner Creek.

Table 8-5. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project CON-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	4						

Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4). Conner Creek is the only facility with outdoor sodium hypochlorite storage. There are two alternatives:

- 1) **Alternative 1: Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals.** Heat tracing with a monitoring system is currently used on chemical piping. Heat tracing, however, can fail and could cause the contents of an entire tank to spill into the containment area. This alternative assumes continued use of heat tracing with a monitoring system. Provisions for an improved system and, potentially replacement of the system before the end of its useful life should be considered to improve reliability.
- 2) **Alternative 2: Provide a New Building to Enclose Storage Area.** The existing structure surrounding the Chemical Storage Area consists of concrete masonry unit block wall with exterior brick. This wall is shorter than the tanks. While this wall could be integrated with a building to enclose the tanks, additional columns would be required to support the roof. A building would also require heating and ventilation, and possibly air conditioning, facility electrical (e.g., lighting and additional electrical outlets as needed), and fire protection (e.g., sprinklers). Air conditioning is often practiced with hypochlorite because the degradation rate is higher with higher temperature. Site glasses are also desired on the tanks.

For cost estimating purposes, a column supported roof and additional wall height necessary to enclose the tanks and integrate with the existing containment walls was the basis for the new structure. Provisions for HVAC, electrical and fire protection are included in the cost estimate.

The alternative evaluation is presented in Table 8-6. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 for heat trace system is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the heat trace system useful life is assumed to be 10 years. To be consistent with the building life in Alternative 2 (60 years), the cost of the heat trace system is multiplied by 5.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title. The building life is assumed to be 60 years in this analysis.

As shown in Table 8-6, Alternative 2 has a Total Benefit score about 1.2 higher than Alternative 1 because of the improved health and safety, component performance, and ease of O&M. However, the NPV/Benefit is much larger for Alternative 2 compared to Alternative. Therefore, **Alternative 1 is the recommended alternative.**

Table 8-6. Alternative Evaluation for Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals	Health and Safety	2	2.40	\$ 864,000	\$ -	\$ 864,000	\$ 360,000	Best Value Alternative
	<i>Definition:</i>	Replace/upgrade existing heat trace system	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Heat tracing can fail without notice or indication, causing pipe rupture	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide a New Building to Enclose Storage Area	Health and Safety	4	3.60	\$ 3,856,000	\$ -	\$ 3,856,000	\$ 1,071,111	
	<i>Definition:</i>	Enclose area around storage tanks and piping	Water Quality & Compliance	3						
	<i>Adv.:</i>	Enclosure provides temperature-controlled space, which would prevent freezing.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.3 Odor Control

8.2.3.1 Description of Existing System

The Conner Creek odor control system consists of four dual-bed vertical carbon adsorbers, one for each retention basin compartment, located near the effluent end of the retention basin. Air is pulled from the Headworks Building, down through the floor opening in the Retention Basin, and then up through the odor control vessels at the downstream end of the retention basin. Each system treats 25,000 cfm of air. Carbon is replaced through the top and side access hatches on the vessel.

The system was installed in 2005. Overall, the system was in fair condition with two systems out of service due to fan issues at the time of the Needs Assessment.

This odor control system operates under air permit requirements (Permit to Install No. 69-06). There is no H₂S emission limit but there is a six-minute average of 20 percent opacity limit. No testing of carbon for remaining bed life is required by the permit. The carbon has not been replaced since installation.

Per GLWA, no odor complaints have been received for at least the past three years.

8.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- The odor control vessel has a dome top which increases the risk of slipping during carbon replacement.
- Jacobs odor control team notes that the majority of carbon systems are provided with simple differential pressure gauges for local monitoring. Regular monitoring of differential pressure gauges is not necessary as the pressure differential changes gradually over time and is not a critical operating parameter. SCADA monitoring is not necessary given the infrequency of operation. As such, remote monitoring of pressure drop across the carbon beds via SCADA is not recommended.
- During the site visit on 1/27/20, only Odor Control Unit 4 was in operation. The magnehelic pressure gauges showed no pressure loss through either vessel carbon bed in the dual bed vessel. The magnehelic pressure gauge across the grease filter indicated a pressure drop verifying air movement by the fan. Either the gauges are not operating, the magnehelic pressure gauge tubing is reversed, gauge ports are blocked, or there is no carbon in the vessel.

To address the lack of carbon bed pressure drop across Odor Control Unit 4, GLWA should inspect the vessel for carbon media. If the carbon media were removed at some point in the past and not replaced, there would be no pressure drop. If there is carbon in the vessel, check that the magnehelic pressure gauges are properly installed. If the gauges are installed properly, try an operating gauge from another vessel on Unit 4 to verify the pressure drop. Another possibility is the gauge ports are blocked by carbon or some component of the tank interior resin or coating. A pipe cleaner or compressed air can be used to check for blockage of the port connection and to remove loose obstructions.

8.2.3.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Access to Odor Control Vessel (Project CON-OC-1). Staff indicated that carbon replacement at the facility would require constructing scaffolding to safely access the top of the carbon vessel for replacing the top carbon bed. The vessel has a dome top increasing the risk of slipping.

Jacobs evaluated two alternatives that would make accessing the top of the carbon vessel safer for both sampling and carbon replacement.

- 1) **Alternative 1: Erect scaffolding for Carbon Replacement.** The O&M staff currently erects a scaffolding when replacing the carbon. The carbon needs to be replaced every 10 years.
- 2) **Alternative 2: Ladder and Railing System.** Figure 7-6. in the BLI facility section above shows a ladder and railing alternative. The figure does not show a 6-in. toe rail, which is recommended, that should be installed at the bottom of the railing to help prevent a person's foot from slipping off the domed top along with tools and equipment. A contractor would field install fiberglass clips and receptacles to the fiberglass tank to secure the ladder and railing. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.
- 3) **Alternative 3: Ladder, Platform and Railing System.** Figure 7-7 in the BLI facility section above shows an example of a ladder, platform, and railing on a horizontal tank. The platform provides a more stable working surface than the domed top. The option is a safer option because the platform provides a flat surface on which to stand. A contractor would field install fiberglass clips and receptacles to the fiberglass tank to secure the ladder, platform and railing. Installation of the platform and rail option is more expensive than the railing only option (Option 1) as a crane is necessary to remove the metal roof and lower the platform from above. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.

The alternative evaluation for these alternatives is presented in Table 8-7. The sources of costs used in this evaluation are listed below:

- The O&M cost for alternative 1 is based on \$10,000 per carbon column for erecting scaffolding. Since, the carbon is replaced once every 10 years, the annual O&M cost is assumed to be \$4,000.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C, under this project title. The standard markups for design, construction assistance and contractor overhead and profit have been applied.

This evaluation shows that Alternative 1 – Erect scaffolding for Carbon Replacement has the lowest NPV/Benefit ratio. **As such, Alternative 1 – Erect scaffolding for Carbon Replacement is the recommended alternative.**

Table 8-7. Alternative Evaluation for Access to Odor Control Vessel (Project CON-OC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Erect Scaffolding for Carbon Replacement	Health and Safety	2	2.50	\$ -	\$ 4,000	\$ 84,359	\$ 33,743	Best Value Alternative
	<i>Definition:</i>	Continue to use scaffolding when replacing carbon.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Must be set up every time carbon is replaced.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Ladder and Railing System	Health and Safety	3	3.22	\$ 138,000	\$ -	\$ 138,000	\$ 42,902	
	<i>Definition:</i>	Provide a ladder on side of vessel and railing around top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Ladder provides improved access and railing provides safety during carbon change-out.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Surface of dome is still sloped and not as safe as a flat surface.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Ladder, Platform, and Railing System	Health and Safety	5	4.00	\$ 410,000	\$ -	\$ 410,000	\$ 102,500	
	<i>Definition:</i>	Provide a ladder on side of vessel and a platform and railing system on top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Platform provides more stable working surface of top of vessel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

8.2.4 Flushing and Dewatering

8.2.4.1 Description of Existing System

Dewatering System: The basin and upstream hydraulic structures are dewatered mostly by gravity. Four submersible dewatering pumps located in a sump area in the central portion of the CSO basin (between Compartments 2 and 3) are used when gravity flow rates decline below pumping rate. The total volume of stored CSO after an overflow event is 62 MG, with 30 MG in the basin and 32 MG in the upstream structures. The volume of 62 MG was designed to be dewatered to the DRI in a 48-hour period. The rate of dewatering is controlled based on the level in the DRI.

Each pump discharges through a dedicated pipe to a junction chamber located next to the basin. All four pumps are intended to operate simultaneously. If one of the dewatering pumps is out of service, a flushing pump can be put into service.

Flushing System: A flushing gate system is used for cleaning solids from the bottom of the basin. Flushing gates with reservoirs were constructed at the following locations: 1) at each side of the screening distribution channel (upstream of the screens); 2) at each side of the basin distribution channel (i.e., the channel downstream of the screens); and 3) at the influent and effluent ends of the four basin compartments. The flushing reservoirs fill with wastewater as the facility fills during a wet weather event. Once the facility is dewatered, water remains in the reservoir. When the flushing gates are actuated, a surge of water is discharged down the channel, scouring solids and moving them into the sump areas. Flushing solids pumps are used to pump this water and solids mixture to the DRI. See Table 8-8 for the location and capacity of the pumps. If additional flushing is needed after the initial flush, NPW can be used to re-fill the reservoir.

The facility receives a significant amount of grit and large debris from the collection system. Because of the large accumulation of grit and heavy solids in the Screening Distribution Channel (upstream of the screens), the flushing gates and flushed solids pump (FSP-1) are ineffective in this area. In fact, FSP-1 has been removed and GLWA staff must use water hoses, vactor truck hoses and portable pumps to remove the solids from this channel.

For the influent sewer area ahead of the Screening Distribution Channel, a bobcat is lowered through a hatch to aid in moving the solids to the hatch area for subsequent removal. Solids are typically loaded into a small container to be lifted out through the hatch and loaded into a larger dumpster at ground level.

Table 8-8 provides an overview of the existing flushing and dewatering system at Connor Creek CSO facility.

Table 8-8. Overview of Existing Flushing and Dewatering System at Connor Creek CSO Facility

Parameter	Value
Total Basin Volume (MG)	30
Headworks and Basin Dewatering and Flushing System	- Flushing gates are installed in 1) Screening Distribution Channel; 2) Basin Distribution Channel; 3) Each Basin Compartment (4 total) 8 flushing gates for each channel or compartment (48 total) - FSPs are used to remove flushed solids from each compartment. - FSP-1 in the area ahead of the screens has been removed due to excessively high grit levels - FSP-2 in the Basin Distribution Channel is 735 gpm at 39.8 ft TDH - FSP-3 and 4 in the middle of the basins are 1,610 gpm at 51.5 TDH - Gravity dewatering can occur down to about 84 ft via in-system storage gates. - Four dewatering pumps. Capacity varies with water level in basin from 7,600 gpm at 12.3 ft TDH (basin full) to 4,475 gpm at 45.5 ft TDH (basin empty). Flow is routed to the DRI

Note:

TDH = total dynamic head

8.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids builds up in the Screening Distribution Channel (upstream of the screens). The removal of solids is labor intensive and costly, and some areas are inaccessible to the bobcat.
- Filling the flushing reservoirs after the first flush uses a significant amount of potable water, which is costly, and is a time consuming exercise. Also, water fills a group of four reservoirs by filling one reservoir and subsequently overflowing into the next three, one at a time. If one of the first flushing gates leaks, the downstream reservoirs do not get filled.
- Accumulation of sediment within the Conner Creek channel could potentially limit the discharge capacity of the facility.
- Many flushing gates do not function properly. Based on an inspection of each flushing gate in late 2019/early 2020 by a contractor, many of the gates do not function properly, making cleaning the basin difficult, if not completely ineffective, and time-consuming. GLWA is currently addressing this issue through rehabilitation of the existing gates through a JOC. As such, this project is not included in the capital improvement projects under CS-299.

8.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screening Distribution Channel Improvements (Project CON-FD-1). A significant amount of grit builds up in the influent conduits to the Conner Creek Basin and in the Screening Distribution Channel. The build-up of solids (typically 3 to 6 ft high over time) prevents the flushing gates in the Screening Distribution Channel from being able to flush the solids to the sump area and it has overwhelmed FSP-1. Due to the significant quantity of grit, considerations to improve or modify the existing grit removal system were quickly dismissed.

The most effective method of grit removal for this CSO facility has proven to be using a bobcat to load the grit into dumpsters. In 2017, GLWA added a large (8-ft × 12-ft) equipment hatch to the influent conduit area to lower a bobcat into this area. This opening is also used to remove the grit from influent conduit area using a small container and dumping it into a larger dumpster located at the surface.

The flushing channels cannot be cleaned out by a bobcat since the channels are not accessible. To make them accessible, the leading alternative is to remove the training walls of the flushing channels, install ramps for the bobcat to access the channel area and fill the FSP-1 area with concrete. This concept is shown in several figures (Figure CON-FD-1-ALT-2) in Volume 6 – Appendices, Appendix B, and described further below.

There are two alternatives for addressing this issue:

1) **Alternative 1: Do Nothing/ Continue to Manually Clean Area**

2) **Alternative 2: Screening Distribution Channel Improvements.** This alternative includes the following:

Demolition of existing concrete and equipment. The recommended improvement involves demolition of the existing flushing gate channel training walls, flushing gate assemblies, and the front flushing gate reservoir walls. The anticipated demolition method is jackhammering, which will remove the concrete down to below the adjacent floor system. Rebar will be cut below the floor surface as well. High-strength concrete patching materials will be applied to create an overall smooth surface on the flushing floor. By removing this concrete, O&M staff will be able to maneuver around the area freely to collect sediment

Concrete Fill. The flushing wave collection channel will be filled in with concrete to be level with the floor surface. The FSP-1 sump will be cleaned and partially filled with concrete to result in a shallower sump, approximately 2 ft below the flushing floor edge.

Drain Pump System Reconfiguration and Reinstallation. The FSP-1 sump pump was previously removed by GLWA due to consistent pump fouling by sediment. Jacobs recommends constructing a more robust screen around the FSP-1 sump and reinstalling the pump and discharge piping. The benefit of reinstalling a protected pump is the ability to consistently dewater the influent channel area after all events, and to dewater the space more effectively prior to grit removal.

The more robust sump pump screen concept consists of a static screen installed around the existing sump. Four 6-in. bollards will be set inside the FSP-1 sump prior to concrete filling. A stainless-steel perforated screen will be fabricated with 2-mm openings (similar material and opening size to screens used for dewatering sumps in construction excavations). The screen fabrication will be approximately 10 ft high and will be positioned over the bollards, with the bollards serving to maintain the screen in its location. The screen unit will be sufficiently heavy to remain in place during inundation by CSO events but can be lifted from the surface to a height necessary to clean any debris that may accumulate inside the screen.

The FSP-1 sump pump will be reconfigured such that the pump suction intake is 2 ft above the sump floor with a welded stainless steel bracket. The operational setting for this pump will be reprogrammed to start operation once the minimum pump submergence level has been detected (requires level sensor element control) and will stay in operation for the duration of the event. A provision for a secondary water jet should be provided at the intake to support the dewatering. With the perforated screen in place, and the pump in continuous operation, the sediment loading inside the screened area will be significantly minimized, allowing the influent channel to be adequately dewatered following each event. The perforated screen can be lifted from the surface if needed to access the sump area.

Access to Screening Distribution Floor. To facilitate access to the floor from the influent conduit access hatch, two concrete ramps will be poured with a 12H:1V slope (approximately 8 degrees). Concrete bollards (6-in. diameter, 4 ft tall) will be set along the edge of the upper level at 6-foot spacings and along the edge of the ramp to the cleaning floor, effectively guiding equipment operators to the ramp during sediment removal and preventing driving over the edge.

At-Surface Sediment Removal. To support a more efficient removal of sediment from the area upstream of the bar screens, a series of 8 ft × 8 ft openings will be cut into the influent channel roof. A surface mounted conveyor unit will be extended into the opening down to the floor, where the bobcat operator can deposit sediment in a hopper. See Figure 8-3 for an example of a conveyor that could be used. The conveyor will lift the sediment to the surface and deposit the material into a dumpster or directly to a dump truck for off-site disposal. As the operator systematically cleans the area, the conveyor can be rotated to different positions using a crane from the surface as needed to minimize bobcat travel. Once a general area has been cleaned, the conveyor is retracted and relocated to another opening. The sequence is repeated until the entire upper level and floor has been adequately cleaned. Additionally, the openings through the roof slab facilitate easier access to the influent channel during construction. The conveyor used as a basis of the concept can be viewed online at www.interquip.net. When not in use, the conveyor belt unit would be disassembled and stored onsite. GLWA staff will need to identify a potential location where the stored unit does not interfere with day-to-day O&M. A covered storage structure (e.g., canopy cover, prefabricated metal shelter) and paved surfacing at a preferred storage location is not included in the capital cost estimate.

Figure 8-3. Example of Surface Mounted Conveyor Unit

Flow management during construction will be a major consideration for this option. Bypass pumping is not feasible, given the potentially large flows and isolating the areas of concrete addition will not be cost effective. Constructing concrete sections for the channel infill and the two concrete ramps above-ground and lowering into place should be considered. This issue will require much further evaluation during detailed design.

New Storage Building. A new 30-ft by 60-ft prefabricated metal building with a concrete slab-on-grade will be constructed near the existing building. The building will be used to store the conveyor, stop logs, and other spare parts for the facility.

The alternative evaluation for these alternatives is presented in Table 8-9. The sources of costs used in this evaluation are listed below:

- The O&M cost for Alternative 1 includes GLWA labor cost and water usage cost. The labor cost is based on 3 staff for 80 hours per week and 4 times per year, or about \$100,000 per year. Water usage assumes a water jet is needed to break-up the solids and convey them to the sump area. Water usage based on about 1 MGD needed for 8 hours per day during the 2 week period at \$4,000/MG, or about \$56,000 per year.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$200,000 for cleaning/re-cleaning the Screening area, and another \$200,000 allowance for wet weather interruptions/delays.
- The O&M costs for Alternative 2 is based on GLWA labor cost of 2 staff for 20 hours per week and 8 times per year, or about \$16,000 per year.
- Grit disposal costs are assumed to be similar for the two alternatives and, therefore, not included.

This evaluation shows that the Total Benefit score for Alternative 2 is 2.0 higher than Alternative 1 because of improved health and safety and ease of O&M. In addition, it is the best value alternative. **As such, Alternative 2 – Screening Distribution Channel Improvements is the recommended alternative.**

Table 8-9. Alternative Evaluation for Screening Distribution Channel Solids Build-Up (Project CON-FD-1)

Alt.	Description	Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i> Do Nothing	Health and Safety	1	1.72	\$ -	\$ 156,000	\$ 3,289,983	\$ 1,916,495	
	<i>Definition:</i> Continue removing solids from portion of basin using bobcat and bucket	Water Quality & Compliance	2						
	<i>Adv.:</i> Known system	Capacity Enhancement	3						
	<i>Disadv.:</i> Labor intensive, solids typically remain due to incomplete cleaning - thus solids could be scoured out of basin in a subsequent storm.	Component Performance	3						
	<i>Comments:</i> None	O&M Ease	1						
2	<i>Alt. Name:</i> Screening Distribution Channel Improvements	Health and Safety	4	3.72	\$ 2,880,000	\$ 16,000	\$ 3,217,434	\$ 865,677	Best Value Alternative
	<i>Definition:</i> Modify floor of channel to remove training walls and add ramps for bobcat; fill flushing wave collection channel with concrete; reconfigure and reinstall Flushing Solids Pump 1; provide removable solids removal conveyor.	Water Quality & Compliance	3						
	<i>Adv.:</i> Will make solids removal less labor intensive, less costly and safer.	Capacity Enhancement	3						
	<i>Disadv.:</i> None.	Component Performance	3						
	<i>Comments:</i> None	O&M Ease	5						

Flushing Water System Improvements (Project CON-FD-2). The flushing reservoirs in the basin and influent area are naturally filled with combined sewage during storms that fill at least one-quarter of the basin. The volume of water captured in the flushing reservoirs is used to flush the settled debris from the floor of the basin. If additional flushing is needed, NPW (i.e., City water that has gone through the backflow preventer) must be used. GLWA Operations personnel have noted that it takes about 10 hours to fill all the flushing reservoirs with water using the water lines. Based on the active reservoir volume of 0.4 MG, this implies that the average flow rate is about 700 gpm. Operations personnel also note that there is a drop in water pressure for hose washdown in the basin when the flushing reservoirs are being filled. The reservoir fill lines and hose drop connections are fed from the same service water system in the basin. The header for this system is an 8-in. diameter water line. The basin flushing water is fed from the facility's service water system that originates from a 12-in. connection on Freud Avenue.

There are three alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Continue Using Potable Water**
- 2) **Alternative 2: Flushing Water System Improvements Using River Water.** This alternative involves using water from Conner Creek for flushing water. The gravity-fed system would consist of two 12-in. HDPE header pipes located across the basin to service the flushing reservoirs. See figures (Figure CON-FD-2-ALT-2) in Volume 6 – Appendices, Appendix B, for a plan view and section view, respectively, of this option. Each header would originate on the east side of the basin in the canal where the pipe would penetrate the basin wall. A screen (manually cleaned) is shown at the inlet of each pipe to prevent large objects from entering the header pipe. Platforms are provided at each inlet to allow for cleaning the screen, if necessary. The installation of this system will require intake structures, along with accompanying cofferdams, to be constructed at each intake into the basin from the canal.

The screened inlet must be located at an elevation below the Detroit River low water datum, which is approximately elevation 93.0 ft (City of Detroit Datum). At this river elevation, there would be a minimum of 12 ft of static head between the river elevation and the elevation of the discharge points at the flushing reservoirs. A motorized control valve would be located on the header pipe at each set of flushing reservoirs. After each valve, GLWA has requested piping to each individual reservoir, which allows for filling each reservoir even when there is a leak (i.e., a leak at the flushing gate) in the first reservoir. It is anticipated that each header could convey approximately 2,000 gpm, or nearly 3 million gallons per day (MGD). The influent and effluent flushing reservoirs could be filled independently. This modification, along with higher flows, would significantly reduce the time to fill the reservoirs.

The advantages of this gravity system, compared to a pumping system, are:

- City water savings (see alternative evaluation for details)
- Few moving parts to be maintained
- Lower maintenance cost
- Lower capital cost
- Ability to fill influent-end and effluent-end flushing reservoirs at the same time, thus significantly reducing the time to fill the reservoirs
- Ability to fill four reservoirs at a time, instead of filling one reservoir and allowing the water to overflow into subsequent reservoirs, by using a valve to control flow to the group of four reservoirs and extending a pipe with discharge to each of the four reservoirs.

The disadvantages of the gravity system, compared to a pumping system, are:

- Valve actuator being at the deck level will have 25 to 30 ft long stem requiring several braces spaced along the height of the valve stems.

- Potential blockage of screens due to zebra mussels

The attachment of zebra mussels on the intake screen or in the intake pipe will decrease screen inlet flow area and pipe diameter reducing flushing reservoir filling rates or completely restricting flows to the individual flushing reservoirs. Allowing zebra mussels to colonize the intake pipes will also provide them with an opportunity to enter the basin where further colonization may occur. For these reasons, it is recommended that a zebra mussel control strategy be implemented at each of the intake pipe locations for the gravity-feed system. There are a variety of mussel control measures ranging from treatments with chlorine and other oxidants, mechanical removal, and special pipe coatings. Sodium hypochlorite is commonly used to control zebra mussel growth. Extension of the Conner Creek CSO hypochlorite system to the raw water inlets may be the simplest approach as hypochlorite does not need to be applied continuously. Intermittent application of 1.0 mg/L hypochlorite during the breeding season in the summer is usually sufficient. Many utilities apply hypochlorite to the front edge of water intake pipes to prevent mussel colonization and to kill any mussels that have already attached. GLWA currently applies hypochlorite at the Belle Isle intake structure to control zebra mussels on the intake screens and within the intake structure and tunnel. Such practices are therefore recommended at the respective intake areas at the Connor Creek facility.

It should be noted that an application for water withdrawal from EGLE in excess of 2 MGD is required. The need for this permit will need to be further explored during detailed design phase. Water is not being diverted from the Great Lakes basin so obtaining a permit should not be a problem.

- 3) **Alternative 3: Flushing Water System Improvements Using Potable Water.** This alternative involves continued use of City water from Conner Creek, with the addition of the valves and piping to allow the groups of four reservoirs to fill at one time, as described in Alternative 2. Instead of tying into the river water piping, this proposed system would tie into the existing potable water system.

This alternative would have the advantage of being able to fill reservoirs downstream of leaking flushing gates. It would have the disadvantage of using a significant amount of City water and would still take a long time to fill all the reservoirs with water.

The alternative evaluation for these alternatives is presented in Table 8-10. The sources of costs used in this evaluation are listed below:

- The annual O&M cost for Alternative 1 and 3 is based on water usage of 800,000 gallons per event, 25 events a year, and a unit cost of \$4,000 per MG. The annualized cost of water is about \$80,000.
- The capital cost for the proposed flushing systems (Alternatives 2 and 3) are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 2 includes \$2,000 for equipment maintenance.

This evaluation shows that Alternative 1 – Do Nothing/Continue Using Potable Water, is the best value alternative. However, this alternative does not provide an acceptable level of cleaning when there are leaking flushing gates. Alternative 2 and 3 provides a solution to this issue. The NPV/Benefit cost for Alternative 3 is greater than Alternative 2. Because Alternative 2 provides the best value alternative compared to Alternative 3, **Alternative 2 – Flushing Water System Improvements Using River Water is the recommended alternative.**

Table 8-10. Alternative Evaluation for Flushing Water System Improvements (Project CON-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Continue Using Potable Water	Health and Safety	3	2.68	\$ -	\$ 80,000	\$ 1,687,171	\$ 628,759	Best Value Alternative
	<i>Definition:</i>	Continue to use potable water to fill reservoirs	Water Quality & Compliance	3

	<i>Disadv.:</i>	Significant amount of City water usage; time consuming	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing Water System Improvements Using River Water	Health and Safety	3	3.32	\$ 2,692,000	\$ 2,000	\$ 2,734,179	\$ 824,376	
	<i>Definition:</i>	Use river water as source of flushing water	Water Quality & Compliance	3						
	<i>Adv.:</i>	Reduced potable water usage/cost; less time to fill reservoirs; lower maintenance cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Zebra mussel control	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Flushing Water System Improvements Using Potable Water	Health and Safety	3	3.32	\$ 1,332,000	\$ 80,000	\$ 3,019,171	\$ 910,303	
	<i>Definition:</i>	Continue to use potable water to fill reservoirs; add distribution to each reservoir	Water Quality & Compliance	3						
	<i>Adv.:</i>	All reservoirs can be filled even if there is a damaged gate	Capacity Enhancement	3						
	<i>Disadv.:</i>	Significant amount of City water usage; long time to fill reservoirs	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.5 HVAC

8.2.5.1 Description of Existing System

The Conner Creek CSO Facility consists of a Headworks, chemical room, chemical storage area (outdoor), utility support (electrical, transformer and mechanical rooms), control room, sample room, hydraulic room, office space on the second floor, and other miscellaneous rooms. The facility also includes adjoining retention basin. Table 8-11 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, gas-heater water heater, electric water coolers, emergency shower/eye wash, and washroom shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 8.2.10.

Table 8-11. Major HVAC Equipment at Connor Creek CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	MAU-1 and 2	2 × Make-Up Air Units	44,000 CFM
Basin	ICEF-1 to 6	6 × Exhaust Fan (Influent Area)	50,200 CFM
	SF-1 to 24	24 × Supply Fan (Basin Deck)	45,000 CFM
Control Building	AHU-1	Air Handler	21,000 CFM
Chemical Room	EF-3	Exhaust Fan	4,140 CFM
	AHU-2	Air Handler	4,080 CFM
Electrical Room	EF-5	Exhaust Fan	2,893 CFM
	EUH-2	Electric Unit Heater	10.2 MBtu
Transformer Room	EF-4	Exhaust Fan	3,130 CFM

Note:

MBtu = million British thermal unit(s)

Table 8-12 provides a summary of the basis of design performance criteria for HVAC systems at Connor Creek and Table 8-13 provides the outdoor Basis of Design conditions.

Table 8-12. Connor Creek Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks Building	Class I, Div 1, Group D (Per Basis of Design Report)	60	N/A	12 ACH (Occupied) 6 ACH (Unoccupied)
Mechanical and Electrical Rooms, Transformer Room, and Maintenance Shop	Unclassified	60	104	Heat Relief
Control Room	Unclassified	72 F Dry Bulb, 50% Relative Humidity	72 F Dry Bulb, 50% Relative Humidity	20 cfm per occupant
Office, Sample Room, Toilet Rooms and Hydraulic Room	Unclassified	72 (Occupied), 60 (Unoccupied)	75 F Dry Bulb, 50% Relative Humidity	50 cfm per flushing fixture (restrooms)

8.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- Inadequate heating in maintenance shop and electrical room: O&M staff noted that the Maintenance Shop gets cold in winter months and electrical room to a lesser degree.
- Uneven heating was reported in the Control Building
- High temperatures in transformer room: Based on investigation by Jacobs, the basis of design summer dry bulb temperature for transformer room is 104°F. It is therefore not unusual that relatively high temperatures are observed in this space. During the site visit by Jacobs, exceedingly high temperatures were not noted in the transformer room; however, the door to the transformer room was open and the exhaust fan was observed to run at a low rpms, likely indicating a reduced airflow capacity. Additionally, the thermostat did not appear to be functional based on the fact that the exhaust fan remained on and the supply air damper remained open when the thermostat was adjusted to a setpoint above the space temperature. This is not considered a capital need.
- GLWA staff reported malfunctioning dampers in chemical room, maintenance room, electrical room, and transformer room. During the Jacobs site visit, the Maintenance Shop and electrical room motorized dampers were tested for functionality. The dampers responded to changes in the thermostat setpoint; however, there was a delay in the response. This delay is normal and does not require any corrective actions. The transformer room damper was observed to be open and the exhaust fan running; however, the damper and fan did not respond to changes in the thermostat setpoint. This issue should be investigated and corrected by maintenance staff and is not considered a capital need.
- Chemical room AHU-2 is difficult to replace due to limited size of door openings to the chemical room.
- O&M staff would like a shower in the upstairs men's and women's restrooms.

During the discussions with Dunbar Mechanical, GLWA's HVAC contractor, the following historical issues were noted:

- Heating Improvements in Control Building: GLWA's HVAC contractor noted that on/off control from the duct heaters in the Control Building was replaced with a controller that modulates the gas valves to maintain a minimum supply air temperature.
- Replacement of Duct Heater: GLWA's HVAC contractor noted that one of the three gas duct heaters had been recently replaced.

- Humidity Issues in exterior rooms: GLWA's HVAC contractor noted that major humidity issues had occurred in the North and East exterior room in the Control Building. Jacobs notes that several factors could be contributing to the humidity issues noted by GLWA's HVAC contractor. Major contributors include:
 - Insufficient cooling capacity of AHU-1's cooling coil. As noted below, the McQuay condensing unit appears to have a refrigerant leak which would result in a decrease in the ability of AHU-1 to remove humidity from the incoming outside air and return air streams. The recommended replacement of the condensing unit should eliminate cooling capacity as a contributing factor to high humidity levels.
 - Air infiltration into the space. During the site walkthrough it was noted that windows were left open in the Conference Area on the 2nd floor. Major sources of infiltration such as open windows would seriously contribute to the potential for condensation in air-conditioned spaces, particularly in the summer when the outside air dewpoint temperature is likely to be above the dewpoint temperature of interior surfaces.
 - Insufficient ventilation/poor air distribution (which would allow for the buildup of humidity in occupied spaces). The uneven heating noted by GLWA O&M staff could be an indicator of poor air distribution/ventilation. The recommended air balance should eliminate this as a potential contributing factor.

If the humidity issues persist after the recommended air balance study and replacement of the condensing unit, monitoring of the doors and windows using the direct digital controller (DDC) could be considered to determine if there is a correlation between open windows/doors and humidity issues.

During site investigations (June 2020) the following observations were noted:

- A new split DX system had recently been installed in the control room server area.
- The windows were open in the control building second floor conference room.
- The exhaust fan was off in the chemical room.
- Both roll-up doors were open in the headworks area.
- Oil was observed on the McQuay air-cooled condensing unit's (ACCU-1) condensing coil and the compressors were observed to be hissing (see Figure 8-4 below). This observation most likely indicates a refrigerant leak. The unit is 17-years old and a refrigerant leak would result in reduced cooling capacity, which could be contributing to the humidity issues in the control room noted by GLWA's HVAC contractor. Given that the unit is near the end of its useful life and a refrigerant leak is likely, it is recommended that the unit be replaced with a unit of the same capacity and added to the DDC system for monitoring and control. This replacement is included in the SRP.

Figure 8-4. Oil on McQuay Unit Condensing Coil

- The door to the transformer room was open.
- The transformer room exhaust fan appeared to be operating at low RPM.
- The actuator on the transformer room motorized damper appeared to have been recently installed.
- The electrical room overhead door was open.
- The electrical room exhaust fan intake is located very close to the air intake louver with motorized damper.
- The Maintenance Shop exhaust air ductwork is located close to its air intake louver.
- The duct for Basin supply fan SF-22 (located in the Maintenance Shop) is not enclosed in fire-rated walls as indicated on the design drawings (see Figure 8-5 and Figure 8-6).

Figure 8-5. Supply Duct for SF-22 Not Enclosed in Fire-Rated Wall

Figure 8-6. SF-22 Chase Detail (Per 02/06 Project Record Drawings)

8.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Control Building Air Balance Study. As noted in Section 8.2.5.2, the duct heaters in the Control Building have recently had a control upgrade to modulate the gas valves and maintain a minimum discharge temperature instead of being on-off and controlled by wall-mounted thermostats. If this change has not resolved the uneven heating experienced in the Control Building, an air balance study is recommended to determine if heated air is properly being distributed to spaces in the Control Building. If this does not resolve the issues, additional measures can be considered, such as additional duct heaters in spaces which are receiving inadequate heat. Jacobs recently prepared a scope to coordinate air balance study with a Testing and Air Balancing contractor.

HVAC Improvements (Project CON-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: HVAC Improvements** including,

- Maintenance Shop and Electrical Room Heating Improvements
- Chemical Room AHU Access Improvements
- Control Room Wall Extension
- Chase for SF-22 Basin Supply Air Duct
- Shower in Second Floor Men's and Women's Restrooms

Each of the HVAC related improvements listed above are described further below:

Maintenance Shop and Electrical Room Heating Improvements. The basis of design winter dry bulb temperature for the Maintenance Shop and electrical room is 60°F so it is possible that these areas could be perceived as being cold in the winter. Both the Maintenance Shop and electrical room are served by a single 3 kW electric unit heater. Jacobs noted that the unit heater in the Maintenance Shop and electrical room are located on the opposite side of the room from the outside doors, which likely makes for a big difference in temperature across the room during the winter months. It is recommended that an additional unit heater be added to each room.

Chemical Room AHU Access Improvements. To improve ability to remove this unit in the future, the single door to the hallway should be replaced with a double door.

Control Room Wall Extension. A new split DX system was recently added to the control room server area. This space is provided with conditioned air from AHU-1 and is not completely enclosed with a floor to ceiling partition (Figure 8-7). Thermal comfort in the occupied portion of the control room would be improved by extending the existing partition between the two spaces to the ceiling and extending the existing return air duct to the server room area in an appropriate location.

Figure 8-7. Low Wall in Control Room

Chase for SF-22 Basin Supply Air Duct. Per the design drawings, the supply air duct for SF-22 which runs through the Maintenance Shop to the Basin below was designed to be enclosed in a chase, which would create a physical separation between the Maintenance Shop and the supply air duct. A similar chase was constructed in the transformer room for SF-21's supply air ductwork. NFPA 820 requires a gas tight partition between classified spaces (such as the Basin, which is Class I, Division 1) and unclassified spaces, which was the reason the original design included the chase. Without the enclosure for the supply air duct, the Maintenance Shop, and by extension all spaces connected to it, are technically Class I, Division 1 spaces. It is recommended that a

chase be constructed in the Maintenance Shop per the original design drawings to create the required physical separation between the Basin and Maintenance Shop. See Figure 8-6 herein.

Shower in 2nd Floor Men's and Women's Restrooms. Space exists for the installation of showers in the 2nd Floor Washrooms. Although a complete design would require further assessment it seems likely that the drains, vents, and hot and cold water supplies could be connected to the existing plumbing system fairly easily.

During the evaluation of the existing plumbing assets it was discovered that the existing hot water tank only has a 100-gallon capacity. ANSI Z358.1 requires 20 gpm of tepid water for a period of 15 minutes for emergency showers. At the design mixed water temperature of 80°F, design storage temperature of 120°F, and recommended 47°F cold water design inlet temperature, the existing tank would only provide tepid water for 11 minutes. Jacobs recommends that the hot water tank should be replaced with one with a storage capacity of at least 150 gallons regardless of whether the shower upgrades are pursued.

The alternative evaluation is presented in Table 8-14. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- There is no measurable difference in O&M costs between the two alternatives.

This evaluation shows that Alternative 1 is the Best Value Alternative. Under Alternative 2, the chase for SF-22 air duct is a code compliance issue, so it should be implemented during a major project at the facility. Based on this need, **Alternative 2 is the recommended alternative.** However, it is noted that the remaining tasks are not high priority and could be performed at a later date.

Table 8-14. Alternative Evaluation for HVAC Improvements (Project CON-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	4						

8.2.6 Electrical

8.2.6.1 Description of Existing System

The Conner Creek facility's electrical system consists of dual (redundant) 24 kV utility feeds for two unit substations with primary metering and DTE 3,000 kVA indoor dry type transformers. The facility also has one diesel generator feed from a 2 MW, 480/277 V, 3-phase stationary generator. The substations and generator feed into the double ended switchboard main distribution panel (MDP), which has a tie-breaker and automatic source transfer controls. Circuit breakers in the MDP then feed six MCCs and one power distribution panel (PDP). The MCCs and PDP then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 8-15 provides a summary of the major electrical equipment for this facility.

Table 8-15. Major Electrical Equipment at Connor Creek

Location	Major Electrical Equipment	Description
Transformers Room	Transformers T1 and T2 Substations	3,000 kVA, 24 kV-480/277 V, 3-Phase
Outdoors	Generator (Diesel)	2 MW, 480/277 V, 3-Phase
Electrical Room	Double ended switchboard main distribution panel (MDP)	3,200 A, 480/277 V, 3-Phase
Electrical Room	MCC-1	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-3	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-4	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-5	1,600 A, 480/277 V, 3-Phase
Chemical Room	MCC-6	1,600 A, 480/277 V, 3-Phase

8.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

8.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project CON-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating at night and select locations within the basin.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure CON-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - FSP-2 access stairway – Relocate the existing LED wall mounted light fixtures to provide the required foot-candles and code requirements.

- Influent area ahead of Screens – Add LED lighting fixtures to meet the required foot-candles and code requirements for the area.
- Interior effluent end of Basin – Add interior LED wall mounted lighting fixtures to the area to address the required foot-candles and code requirement.
- Exterior effluent end of Basin – Add additional exterior LED lighting fixtures to supplement the current lighting within the area to address the required foot-candles and code requirements.
- Add power receptacles to assist in the maintenance and operations of the facility near the FSP-1 opening.

The alternative evaluation is presented in Table 8-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting. The NPV/Benefit cost for Alternative 2 is \$37,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 8-16. Alternative Evaluation for Electrical Improvements (Project CON-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night and select locations within the basin	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 129,000	\$ -	\$ 129,000	\$ 36,857	Not Applicable
	<i>Definition:</i>	Add additional lighting in the at select locations in the basin and near the effluent.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.7 I&C

8.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2005 under GLWA project PC-739. During the same time period, stand-alone Ovation systems were being installed in the Freud Pump Station and Conner Creek Pump Station under PC-713. The Conner Creek CSO facility was designed to house the main control system for the region. In 2014 under PC-773D, the three facilities were combined into one overall Ovation control system. While the systems were being combined, the system controllers and software were upgraded to version O.V.3.5.0 for all three facilities.

The Conner Creek control system is comprised of primary and back-up network switches to provide the system complete network redundancy. The switches are connected to the GLWA AT&T wide area network via the system's router. These primary and back-up network switches are interfaced to three redundant networks, with one at the Freud Pump Station, one at the Conner Creek CSO facility, and one at the Conner Pump Station. The redundant network switches in the Conner CSO facility are connected to one database server and two operator workstations. All workstations are connected redundantly to the network switches via copper Ethernet cables. Additionally, it has two redundant Ovation controllers connected to the network switches in a dual-homed configuration to provide back-up for controls and I/O capabilities. The current system is equipped with a back-up radio system to communicate critical monitoring points back to SCC on wide area network failure.

The Freud Pump Station has redundant network switches connected to Conner Creek's main control systems primary and back-up network switches in the Conner Creek CSO facility. The networks are connected via fiber optic cables in underground ductbanks between the two facilities. There is a rack mounted workstation and one redundant Ovation controller pair for the station. The Ovation controllers and the workstation are connected in a dual-homed configuration via copper Ethernet cables. Additional local PLCs are connected to the Ovation control system via local system switches.

The Conner Pump Station has redundant network switches connected to Conner Creek's main control system primary and back-up network switches in the Conner Creek CSO facility, similar to the Freud Pump Station. The networks are connected via fiber optic cables in underground ductbanks between the two facilities. There is a rack mounted workstation and one redundant Ovation controller pair for the station. The Ovation controllers and the workstation are connected in a dual-homed configuration via copper Ethernet cables. Additional local PLCs are connected to the Ovation control system via local system switches.

Flow and Level Sensors: Table 8-17 summarizes the level sensors and flow meters at the Conner Creek CSO Facility used to monitor flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 8-17. Summary of Flow Meters and Level Sensors at Connor Creek CSO Facility

Area	Quantity	Instrument Type
CSO Influent Flow Meters		
Influent (East, central, and west influent channel flow, Freud Ashland Relief, Freud Fox Creek Relief)	5	Transit-Time (AccuSonic)
CSO Facility Level Sensors		
Mixing Chambers	2	Ultrasonic
	10	Ultrasonic (back-up)

Area	Quantity	Instrument Type
Flushed Solids Sumps (Dewatering sumps (2), Retention Basin Distribution Channel, Screening Distribution Dchannel)	4	Ultrasonic
Conner Creek	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed Pumps	10	Magnetic
Chemical Mixers and Diffusers		
High Mixers	10	Magnetic
Middle Mixers	10	
Low Mixers	10	
Diffusers	10	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	4	Ultrasonic

8.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section .

- Evaluate the existing level sensors and flow meters to determine redundancy and identify instruments that could potentially be removed. The evaluation and recommended removal of level sensors is presented in the next section.
- Operators have no way to determine whether the dewatering pumps are functioning properly. To address this issue, they requested a new flow meter downstream of the junction chamber to provide indication and rate of flow.
- Evaluate replacement options for valve control network
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system to the latest version and increased monitoring capabilities
- Generator and ATS controls do not adequately report alarm signals into Ovation and are becoming less reliable. This issue is being addressed in an on-going project and is therefore not included in the capital improvement projects for CS-299.
- Need accurate river level measurement. GLWA is currently planning to install a river level sensor through a JOC. This issue is not included in the capital improvement projects for CS-299.

8.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project CON-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation control system upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) Alternative 1: Do Nothing/Replace In-Kind.

- Leave level sensors in place

2) Alternative 2: I&C Improvements including,

- Remove redundant level sensors
- Provide new flow meter for dewatering flow downstream of the junction chamber
- Evaluate replacement options for valve control network
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Remove redundant level sensors. The Conner Creek CSO Facility has 12 level sensors in the chemical mixing chambers downstream of the screens. There are two primary ultrasonic level sensors, one in Mixing Chamber 3 and one in Mixing Chamber 8, and a level sensor in each of the ten chemical mixing chambers. See Figure 8-8 for the location of these sensors.

The level sensor signals are used to turn on and off the lower, middle and upper level mixers based on the water level in the channels. Since all the channels are interconnected downstream of the screens, the water level should be fairly similar between the mixing channels. The readouts for the individual channel level sensors are not available on the Ovation screens. However, while these level sensors act as back-up for the primary sensors in Mixing Chamber Nos. 3 and 8, current I&C configurations rely on the readings from level sensors in individual mixing chambers to run the high, mid-, and low-level mixers. As such, the ten level sensors can be removed, but only if the signal from the primary ultrasonic level sensors are retrofit with an output relay to replace this function provided by the individual channel level sensors.

Modifications to allow removal of these level sensors are included in the cost estimate. Removal of the 10 redundant level sensors will reduce I&C maintenance on these sensors.

Provide new flow meter for dewatering flow downstream of the junction chamber. Operations has expressed a desire to have flow measurement for the dewatered flow that is pumped from the basin to the sanitary sewer. The recommendation is to install a non-contact laser flowmeter downstream of the junction chamber in an existing manhole. This meter should provide accurate enough data in this 48-in. larger diameter sewer. Figure CON-I&C-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the plan and profile of the sewer and the area of interest where the flow meter should be installed.

Figure 8-8. Conner Creek CSO Facility Level Sensor Identification

Evaluate replacement options for valve control network. See Section 5.4.6 for details of the Valve Control Philosophy – Valve Network (Pakscan) versus hardwired control. The recommendation is to continue the use of the Pakscan valve network for data and status while upgrading the 16 effluent relief gates valve controls to hardwired control.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 8-18. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 includes the in-kind replacement for all level sensors.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 include maintenance of the valve control network and the level sensors (downstream of the screens).
- The O&M costs for Alternative 2 include maintenance of the new instruments and cameras. It is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative. The total benefit score for Alternative 2, however, is 0.6 higher than Alternative 1 due to improved component performance and ease of O&M. The NPV/benefit value of Alternative 2 is approximately \$157,000, which is a moderate cost compared to other projects recommended in this assessment. As such, **Alternative 2 - I&C Improvements, is the recommended alternative.**

Control System Upgrade (Project CON-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 8-19 provides the summary of the Control System Upgrade, which is the recommended alternative. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title.

Table 8-18. Alternative Evaluation for I&C Improvements (Project CON-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.68	\$ 60,900	\$ 10,000	\$ 271,796	\$ 101,291	Best Value Alternative
	<i>Definition:</i>	Replace level sensors in-kind.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 331,000	\$ 9,000	\$ 520,807	\$ 157,027	
	<i>Definition:</i>	Removal of redundant level sensors; addition of new flow meter for dewatering flow; provide tank level indication; upgrade effluent relief gate valves controls to hardwired control; and install process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Table 8-19. Alternative Evaluation for Control System Upgrade (Project CON-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,678,000	\$ 1	\$ 1,678,021	\$ 559,340	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.8 Site

8.2.8.1 Description of Existing Site

There is an access road to the site off Freud Avenue. The access entrance gate to the site is a 30-ft wide sliding vehicular gate across the 40-ft wide access road. Site security is provided by a 6-ft high ornamental fence along the north perimeter of the site. This includes the entrance gate located on the south side of Freud Avenue. The fence starting at the west end of the entrance gate extends easterly along the south right of way of Freud Avenue, extending around the stormwater detention pond and then ending at the creek. A 6-ft chain link fence is located at the west perimeter of the site facing the Federal Aviation Administration Tower Area. Site concrete sidewalks are 3 to 5 ft wide and approximately 4 in. thick. The site parking and drive areas are paved with 4.5 in. of asphalt on 10 in. of aggregate. The gravel drive farther south of the building is 8 in. thick.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

8.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- The entrance gate has reached the end of its useful service life
- Water ponds on top of the basin. In the winter, this water freezes and causes safety concerns
- Sidewalks have settled and heaved, causing safety issues and water infiltration next to building

8.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project CON-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) Alternative 1: Do Nothing.

2) Alternative 2: Site Improvements including,

- Replace Entrance Gate
- Address ponding on basin deck
- Replace Sidewalks in Select Areas

Each of the site related improvements listed above is described further below:

Replace Entrance Gate. The entrance gate at the Conner Creek CSO facility is a 30-ft wide automatic cantilever sliding gate. The gate has been subject to numerous recent mechanical failures. The gate has reached the end of its useful service life and is recommended to be replaced with a new similar style gate.

Address Ponding on Basin Deck. There are areas of significant ponding on the basin roof deck. Several of these areas are located on the east side of the deck adjacent to the Conner Creek canal. To remediate the ponding issue, it is recommended that holes be cored through the basin roof to allow discharge of ponded water to the basin. Recessed area drains would be installed in the cored holes to the basin. For those areas adjacent to the canal, scuppers through the basin parapet wall should be investigated to relieve ponded water directly to the canal.

Replace Sidewalks in Select Areas. The sidewalks next to the Control Building have settled, pulling away from the face of the building and allowing water to infiltrate the joints at the base of the building and sidewalks. This leads to heaving of sections of sidewalk and creates uneven sections, which is a safety concern. It is recommended that all damaged concrete sidewalk flags be demolished. In addition, the expansion joints at the face of the wall should be replaced and the joints caulked and sealed to prevent water infiltration.

The alternative evaluation is presented in Table 8-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Alternative 1 based on the improved health and safety and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$24,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 8-20. Alternative Evaluation for Site Improvements (Project CON-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety concerns uneven sidewalks and from ice buildup on the basin in winter.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 85,000	\$ -	\$ 85,000	\$ 24,286	Not Applicable
	<i>Definition:</i>	Replace entrance gate, sidewalks and core holes through deck at low points.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Restores sidewalks and removes water from top of basin.	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.9 Architectural

8.2.9.1 Description of Existing Facilities

The Conner Creek CSO Facility consists of a chemical room, chemical storage room, utility support (electrical and mechanical), control room, sample room, office area, hydraulic room, screen room and other miscellaneous rooms. The facility also includes adjoining retention basin.

8.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

8.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (CON-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Clean and coat bottom of all door frames
 - Remove corrosion from localized areas in roof framing, clean and coat
 - Apply skim coat and slope to redirect water to creek outside the Screening Building

- Provide flashing/ membrane system to protect column bases from ponding moisture to address pooling water between building/brick walls and to fix gap between brick and steel columns
- Clean and repaint surfaces where paint is debonding in Screening Building
- Remove and replace deteriorated ceiling tile in Control Building
- Remove and replace floor control joint sealant
- Investigate and repair water intrusion at door in Screening Building
- Address door hardware issues and door and door frame corrosion issues
- Clean rusted areas of structural steel column base of exterior Screenings Building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure CON-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (CON-DIS-1).

The alternative evaluation is presented in Table 8-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 8-21. Alternative Evaluation for Architectural Rehabilitation (Project CON-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 361,000	\$ -	\$ 361,000	\$ 116,452	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.10 Safety

8.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

8.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 8-22. The capital improvement project to address these issues is included in the table.

Table 8-22. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Headworks – between bar screen No. 8 and No. 9 platforms	Railing does not extend over belt – fall hazard	Extend railing	Safety Improvements (Project CON-SAFE-1)
Stair B6 (Compartment 2) (Representative of all stair locations to basin)	No illuminated exit signs	Add or replace exit signs	Exit Sign Improvements ^a
Headworks – the “walkway” under the screenings conveyor and between grit rollofs	“Walkway” does not meet exit access width requirements – not adequate width, overhead hazard, column in center of walkway	Reroute personnel or the column/overhead horizontal beam will need to be moved	Conner Creek Conveyor Improvements ^b
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project CON-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

^b This project will be completed under the JOC.

8.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project CON-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing between bar screen #8 and #9 platforms to eliminate fall hazard
- Address fall protection

Because the importance of these issues relate to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 8-23 shows the one alternative.

Table 8-23. Alternative Evaluation for Safety Improvements (Project CON-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 358,000	\$ -	\$ 358,000	\$ 119,333	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection and fall hazard.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.11 Supporting Infrastructure

8.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

8.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Dredging of the Conner Creek, based on analysis in the WWMP.

8.2.11.3 Discussion and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section.

Dredging of Conner Creek Channel (CON-SUPP-1). The WWMP investigated the accumulation of sediment within the Conner Creek channel that could potentially limit the discharge capacity of the Conner Creek CSO Facility. During peak wet weather events, it is necessary that the hydraulic capacity of the channel be sufficient to convey overflow from the facility to the Detroit River. Restrictions in the channel could reduce hydraulic capacity causing backup and potential surcharging within the RTB and collection system.

Section 8.8 of the WWMP presents the results of the physical investigation into the amount of sediment that has built up since the facility start-up in 2005. Based on the results of the survey, sediment deposition within the channel varies in depth from 0 to 3 ft, representing approximately 21,000 cubic yards (+/-20 percent) of sediment to be removed.

A cost estimate for dredging accumulated sediment within the Conner Creek channel was developed based on the assumption that the dredging operation will be performed using hydraulic dredging equipment similar to 2005. A material quantity of 35,000 CY was assumed for the estimate, assuming dredging will occur within the next 10 to 15 years. The total estimated cost of the project is \$11 million. For details are provided in Section 8.6 of the WWMP.

8.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Conner Creek CSO facility, Table 8-24 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table

8-24, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 8-24. Listing of Asset Condition Assessments for Conner Creek Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset. Another one of the building asset listed as "PLANNING - ORDERING PARTS/FILLING OUT WORK ORDER/COMPLETING INVENTORY OF PARTS ON HAND. (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is also not an asset.

^b The fire suppression was evaluated Simplex Grinnell in 2018 and not included in the ACES report.

^c The one gas detector is a portable unit and was not assessed.

^d The 46 individual flushing gates were not assessed. These were assessed as a group. The individual gates are being considered for removal from WAM.

^e The second sampler (ES-2) is listed as inactive and is being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the

Conner Creek Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

8.3 Capital Planning for Conner Creek CSO Facility

8.3.1 Summary of Capital Improvement Plan Projects Alternatives

Table 8-25 provides a summary of the recommended CIP projects and associated capital costs for the Conner Creek CSO facility based on the alternative evaluations conducted for this facility.

Table 8-25. Summary of Recommended Projects at Conner Creek CSO Facility

Project No.	Alternative	Description	Total Project Cost
CON-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 2,300,000
CON-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
CON-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
CON-DIS-4	1	Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals	\$ 144,000
CON-FD-1	2	Screening Distribution Channel Improvements	\$ 2,880,000
CON-FD-2	1	Flushing Water System Improvements Using River Water	\$ 2,692,000
CON-HVAC-1	2	HVAC Improvements	\$ 116,000
CON-ELEC-1	2	Electrical Improvements	\$ 129,000
CON-I&C-1	2	I&C Improvements	\$ 331,000
CON-I&C-2	1	Control System Upgrade	\$ 1,678,000
CON-SITE-1	2	Site Improvements	\$ 85,000
CON-ARCH-1	2	Architectural Rehabilitation	\$ 361,000
CON-SAFE-1	1	Safety Improvements	\$ 358,000
CON-SUPP-1	1	Dredging of Conner Creek Channel	\$ 11,000,000

8.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 8-26. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 8-26. Capital Improvement Plan Projects for Conner Creek CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
CON-1 Disinfection System Improvements	\$ 2,456,000	2035 <i>Timing based on asset condition</i>	CON-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 2,300,000
			CON-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
CON-2 Flushing System Improvements	\$ 5,572,000	2028 <i>Timing not dependent on existing asset condition</i>	CON-FD-1	Screening Distribution Channel Improvements	\$ 2,880,000
			CON-FD-2	Flushing Water System Improvements Using River Water	\$ 2,692,000
CON-3 HVAC Improvements	\$ 116,000	2033 <i>Timing based on priority of other needs</i>	CON-HVAC-1	HVAC Improvements	\$ 116,000
CON-4 Facility-Wide Electrical and I&C Improvements	\$ 2,138,000	2029 <i>Timing based on asset condition</i>	CON-ELEC-1	Electrical Improvements	\$ 129,000
			CON-I&C-1	I&C Improvements	\$ 331,000
			CON-I&C-2	Control System Upgrade	\$ 1,678,000
CON-6 Facility-Wide Safety and Architectural Improvements	\$ 719,000	2023 <i>Project should be initiated as soon as possible</i>	CON-ARCH-1	Architectural Rehabilitation	\$ 361,000
			CON-SAFE-1	Safety Improvements	\$ 358,000
CON-7 Dredging of Conner Creek Channel	\$ 11,000,000	2041 <i>Timing of project should be re-evaluated in about 2031</i>	CON-SUPP-1	Dredging of Conner Creek Channel	\$ 11,000,000
CON-10 Model Disinfection Performance	\$ 50,000	2021 <i>Timing based on potential for major maintenance cost reduction</i>	CON-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 8-27 and Table 8-28 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 8-28 indicates that CON-DIS-1 project has two assets that need to be replaced immediately due to condition score of "5". These assets, however, have already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining 109 assets that are included in this project have an average condition score of 1.86 and an average replacement date of 2035. This information was used to propose a scheduled construction completion date of 2035.

Table 8-27. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
CON-DIS-1	109	1.19	1.86	2.28	22	2035	\$ 2,271,000
CON-I&C-2	2	2.29	1.57	4.08	12	2029	\$ 994,990

Table 8-28. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
CON-DIS-1	2	1.29	5.00	4.50	10	2021	\$ 108,000
CON-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -

There are recommended capital improvement projects presented in Table 8-26 that could be better delivered under capital outlay projects. These projects are listed in the following bullets:

- Continue to Use Heat Tracing and Replace at Regular Intervals (CON-DIS-4)
- Site improvements (CON-SITE-1) for the entrance gate replacement, sidewalk repair and basin drainage.

For the CFD Modeling of Mixers (CON-DIS-3), it is ultimately recommended to include this project with similar modeling projects at the Baby Creek and Leib CSO Facilities. See Section 2 (Volume 1 – Project Introduction and Capital Improvement and Outlay Plans) for proposed bundling of this project.

8.3.3 20-Year Capital Outlay Plan

Table 8-29 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 8-29. 20-Year Capital Outlay Plan for Conner Creek CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 751,200	\$ -	\$ -	\$ -	\$ 743,000	\$ -	\$ -	\$ 8,200	\$ -	\$ -	\$ -	\$ -	\$ -

Total	\$ 41,609,855	\$ 408,190	\$ 477,699	\$ 18,578,322	\$ 10,117,804	\$ 1,627,505	\$ 4,604,100	\$ 2,737,954	\$ 126,107	\$ 1,260,424	\$ 252,402	\$ 189,992	\$ 1,229,358

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Flushing gate systems for basin distribution channel, screening distribution channel, and Compartment 1 to 4 received scores of 5 at the time of the Condition Assessment because some of the flushing gates were not functioning. A project to rehabilitate the gates is planned for late 2021.
- Disinfection System: One of the four mixers was covered in debris and the remaining three mixers were out of service at the time of the Condition Assessment (\$50,000 each; \$200,000 total) and received a score of 5. Two chemical feed pumps (\$54,000 each; \$108,000 total) were being repaired at the time of the Condition Assessment. The two Accusonic flow meters (\$217,500 each; \$435,000 total) were not installed at the time of the Condition Assessment.
- Odor Control System: Three scrubber systems (\$1,534,700 each) received scores of 5 since the motor (child of fan) was not functional at the time of the Condition Assessment.

9. Hubbell-Southfield CSO Control Facility

9.1 General Facility Description and Future Capacity Considerations

9.1.1 General Facility Description

The Hubbell Southfield CSO Facility is an RTB with 22 MG of storage, and a treatment capacity of 3,200 cfs. It was constructed in 1996. There are two buildings on site - a Headworks Building and a Control Building. The headworks building contains a headworks area, chemical room, mechanical room, and an odor control area. The control room building contains the control room, odor control room, work area, electrical room, basement area, restroom, locker room, and mechanical room.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

9.1.2 Future Capacity Considerations

There were no future capacity considerations identified at the time of this report.

9.2 Facility Assessment

9.2.1 Screening

9.2.1.1 Description of Existing System

The Hubbell-Southfield CSO Facility has six catenary bar screens that were installed in 1996. Screenings from the screens are discharged to a single conveyor belt, which conveys the screenings to a dumpster. The screenings are disposed in a landfill.

Table 9-1 provides an overview of the existing screening system at Hubbell-Southfield CSO facility.

Table 9-1. Overview of Existing Screening System Hubbell-Southfield CSO Facility

Parameter	Value
Treatment Capacity (cfs)	3,200
No. of Screens	6
Manufacturer	Jones and Atwood
Screen Type	Catenary Bar Screen
Opening Size	1.5-in. slot
Depth or Length / Width	22 ft 0 in / 9 ft 6 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

9.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide a screening retention plate along entire conveyor to prevent screenings from falling off the conveyors at the back of the screens.

- O&M staff noted that the grating over the bar screen channel deflects when walking on it
- Prevent the edges of the bar screen rakes from dragging on concrete. This issue has been added to the scope of the OEM evaluation. This issue has been added to the scope of E&I's assessment, which has not occurred as of the time of this report. If there are capital costs associated with the retrofit to address this issue, it will be added based on OEM input.
- Prevent screens from swaying during operation. During higher flow events, the screens reportedly sway to some degree. The operators believe this is caused by the returning rake getting tossed by the rapid flow of water and affecting the rest of the screen. They noted that the Conner Creek screens (which is a similar screen but does not sway) has chain guide returns that extend closer to the floor of the channel. This issue was added to the scope of the OEM evaluation; however, the OEM was unable to see the swaying because flow did not occur during the site visit. If this issue causes problems in the future, it should be video-taped to document the issue.
- O&M staff noted that the overhead crane pendant is old and bulky.

9.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Screening Improvements (Project HS-SCR-1). Due to the relatively small nature of some of the screening-related projects identified as improvements, all of the identified screening improvements are proposed to be in one project – Screening Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Screening Improvements** including,
 - Screening Retention Plate Along Entire Conveyor
 - Walkway Grating Over Bar Screen Channels
 - Replace Overhead Crane Pendant

Each of the screening related improvements listed above are described further below:

Screening Retention Plate Along Entire Conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt. A cost for a screening retention plate (similar to screening retention plate at Conner Creek) is included in the capital cost estimate.

Walkway Grating Over Bar Screen Channels. O&M staff reported that grating does not feel sufficient (i.e., it deflects when walking on it). A cost for grating replacement is included in the capital costs.

Replace Overhead Crane Pendant. O&M staff indicated the current push-button, explosion-proof crane pendant is old and very bulky (Figure 9-1). Jacobs contacted Crane Technologies to obtain a replacement cost for a new pendant.

Figure 9-1. Existing Pendant for Overhead Crane at Hubbell-Southfield CSO Facility

The alternative evaluation is presented in Table 9-2. Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.

The total benefit score for Alternative 2, however, is about 1.0 higher than Alternative 1 due to improved health and safety, component performance, and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$54,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the advantages with this alternative, Alternative 2 – Screening Improvements is the recommended alternative.**

Table 9-2. Alternative Evaluation for Screen Improvements (Project HS-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.62	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Some screenings fall off conveyor; walkway grating does not seem sufficient; pendant outdated.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Screening Improvements	Health and Safety	4	3.60	\$ 195,000	\$ -	\$ 195,000	\$ 54,167	Not Applicable
	<i>Definition:</i>	Addition of screening retention plate along entire conveyor; replace walkway grating over bar screen channels; replace overhead crane pendant.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Grating would be stronger; Cleaner screening operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.2 Disinfection

9.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP storage tanks, five gear pumps, and three induction mixers. There are six screens discharging into a common influent channel from which flow is directed to Basin Compartment 1 or to the Shunt Channel which can feed Basin Compartment 2. There are three induction mixers located upstream of the bar screens. The sodium hypochlorite pumps discharge to a common header with a flow meter that splits to the three induction mixers, the Shunt Channel, Basin 1, Basin 2, flushing, and odor control. During an event sodium hypochlorite is normally only fed to the three induction mixers. Flow splitting is not metered and there does not appear to be any basis for throttling the valves to individual induction mixers to achieve equal flow splitting. Table 9-3 provides an overview of the existing disinfection system at Hubbell-Southfield CSO facility.

Table 9-3. Overview of Existing Disinfection System at Hubbell-Southfield CSO Facility

Parameter	Value
Treatment Capacity (cfs)	2,200
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L Cl ₂)	10
Disinfection Contact Time (min)	20
Storage Tanks	
Number	2
Volume of Each Tank (gal)	15,000
Type	FRP
Pumps	
Number	5
Capacity (gpm)	10-55
Type	Gear
Mixers	
Number / Type	3 / Chemical induction mixers
Model Number/ hp / Manufacturer	Series 32 / 25 hp / Gas Mastrrr

9.2.2.2 Identified Needs and Issues

The needs and issues identified for Hubbell-Southfield were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Hubbell Southfield chemical feed system has the following issue:
 - The feed pumps are in a confined basement are on short pump pads and as such at risk of being damaged if there was a spill or water leak.
 - The sump pumps in the feed pump area were not designed for corrosive or chemical service and have been damaged by exposure to sodium hypochlorite. Replacement with sump pumps suitable for corrosive chemical service is desired.

These issues are addressed in Replace Chemical Feed System (Project HS-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant,

overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project HS-DIS-2) below.

- Hypochlorite storage capacity is reportedly not enough for large storm events. GLWA requested that Jacobs investigate this issue. Jacobs found that the concrete containment area used for existing spill containment was the original sodium hypochlorite storage. The two existing 15,000 gallons FRP tanks installed in the original concrete storage tanks provide less chemical storage than the concrete tanks. Historical chemical usage from the four largest wet weather events from 2016 through 2018 was evaluated for all of the CSO facilities, including Hubbell Southfield. The data indicate that the volume of sodium hypochlorite fed exceeded the storage volume at Hubbell Southfield in one event. In that event 38,775 gallons was reportedly fed compared to 30,000 gallons storage volume. Chemical deliveries occurred during the event to address this. Based on the event above, additional hypochlorite storage is needed. This issue is addressed in Add New Chemical Storage Tank (Project HS-DIS-3).

9.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project HS-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel. Hose pumps will be larger than the existing gear pumps at Hubbell-Southfield and the need to enlarge the pump area was considered for this alternative. Although not all pumps may fit in the current row of pumps, there appears to be sufficient room to locate a couple of the pumps along the north wall under the stairway if necessary. The costs for demolishing the existing pads and adding new taller and larger pads was included in all alternatives and the cost will not substantially change with pump location. Details regarding pump layout are deferred to design.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to the Hubbell Southfield feed system:

- **Sump Pump:** For cost estimating purposes, a chemically resistant sump pump is assumed for the sump in the chemical feed basement areas as well as hard-piped dilution water to the sump requested by plant personnel.
- **Spill Protection:** Jacobs evaluated two options to address the concern of sodium hypochlorite spill in the pump area, including:
 - **Option 1: Level sensors and raising pump pads.** This option would install a level sensor or contact switch in the pump area. The sensor would be programmed to close actuated valves from the tanks if a spill is detected. Also, this alternative includes raising the pump pads to 2 ft (from their current 4 in.) to further protect the pumps if a spill occurred.
 - **Option 2: Transfer Pump and Day Tank.** This option would include the sensor in Option 1 that would close the tank valves if a spill should occur. This option would also provide a transfer pump and day tank. However, the transfer pumps would remain a weak link in a flood. In order to address this, a vertical shaft

chemically resistant sump pump with the motor located above maximum flood level, as offered by Vanton Pumps, would serve as an emergency backup to a transfer pump. In a flood situation, the sump pump would serve as the transfer pump to the day tank or to return the sodium hypochlorite to one of the storage tanks after that tank's outlet valve is closed.

The cost for a level sensor in the pump area and programming to close actuated valves from the tanks if a spill is detected is a relatively low-cost alternative. As such it is included in Alternatives 2 and 3 above.

The alternative evaluation for these alternatives is presented in Table 9-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 was developed based on GLWA experience of pump rebuilds per year at a cost of \$30,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 9-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 9-4. Alternative Evaluation for Replace Chemical Feed System (Project HS-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System in-kind	Health and Safety	3	2.08	\$ 969,900	\$ 30,000	\$ 1,602,589	\$ 769,243	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 1,130,000	\$ 17,125	\$ 1,491,160	\$ 414,211	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per channel.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 534,000	\$ 3,000	\$ 597,269	\$ 165,908	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project HS-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time must also be considered. The exact location would be determined during design.

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 9-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. Based on the improved ability to meet the NPDES permit TRC goal, **Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 9-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project HS-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Add New Chemical Storage Tank (Project HS-DIS-3). Based on the evaluation performed in the previous section, there is a need for additional chemical storage tank to ensure adequate chemical during larger events. There are two alternatives:

- 1) **Alternative 1: Do Nothing - Rely on Chemical Deliveries during Storm Event.** This approach was used during the large event that exceeded the existing chemical storage capacity. This alternative relies upon an outside contractor to deliver enough hypochlorite to make it through the storm event.
- 2) **Alternative 2: Add New Chemical Storage Tank.** The O&M staff requested a tank at grade to serve as a backup. They also requested the capability for gravity feed to the influent from the new tank in case the pump room floods. The lack of reliable influent flow measurement prevents sizing additional sodium hypochlorite storage based on influent flow, design doses, and assumed hypochlorite strength considering degradation potential. However, the installation of new flow meters in 2019 may help to inform tank sizing for design. For budgeting purposes, a third tank sized the same as the existing two 15,000 gallon tanks is assumed, inside a building with chemical containment, mechanical, electrical and I&C.

As requested by GLWA, the possibility of gravity feed from the chemical tanks with a meter and valve was evaluated. The effluent weir from the CSO basins into the effluent channel controls the hydraulic grade line at the influent induction mixers to above elevation 100 once the basin is filled. The bottom of a new at-grade sodium hypochlorite tank would be approximately elevation 111 and the maximum liquid depth is approximately 13 ft. Thus, there is approximately 11 ft of static head available with the tank empty and 24 ft with the tanks full. This corresponds to 4.8 pounds psig empty to 10.3 psig full available head. The induction mixers require back pressure valves to prevent siphoning chemical. Evoqua recommends a setting of 15 psig. Therefore, the available static head is inadequate for gravity feed before even accounting for friction loss and flow control valve loss. Thus, continued pumping as the means of chemical delivery is recommended.

The alternative evaluation is presented in Table 9-6. Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.

As shown in Table 9-6, Alternative 2 has a Total Benefit score about 1.5 higher than Alternative 1 because of the improved water quality and compliance (i.e., facility could run out of chemical during a storm and violate permit), and ease of O&M. Because of the risk of violating permit, **Alternative 2 is the recommended alternative.**

Table 9-6. Alternative Evaluation for Add New Chemical Storage Tank (Project HS-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	4						

9.2.3 Odor Control

9.2.3.1 Description of Existing System

The Hubbell Southfield odor control system consists of two separate horizontal cross flow scrubber systems. Odorous air flows horizontally across the empty scrubber chamber and scrubbing solution is sprayed into the oncoming air from numerous spray nozzles. One system, located in the Headworks Building, treats air from the Headworks area and Basin No. 1. A second system, located in the Process Building, treats air from Basin No. 2. The systems were originally designed with the capability to spray a solution of sodium hypochlorite and sodium hydroxide to remove odorous gasses. However, the sodium hydroxide has not been used for some time. The chemical solution is recycled through the scrubber and recirculation tank, and fresh sodium hypochlorite is added as needed. Excess chemical solution overflows out of the recirculation tank into a drain.

The system was installed in 1996. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no formal odor complaints have been received for at least the past three years; however, the golf course has indicated that they can smell the facility.

9.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack. (This could be considered during the winter months when the golf course is not active, but is not recommended when the golf course is being used.)

Odor Study. Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous or non-detectable to receptors. Prior to implementing either one of these options, GLWA should conduct an odor study to sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water. The study would also sample the discharge when using water spray, to determine the measured effectiveness of such an operation.

9.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs."

9.2.4 Flushing and Dewatering

9.2.4.1 Description of Existing System

Dewatering System: Basin dewatering can be accomplished by gravity or pumping. Gravity dewatering to the Northwest Interceptor (NWI) occurs by opening one of two flow control valves (BD-1 or BD-3). A control system regulates the valve position and corresponding flow from the basin to the NWI. The gravity discharge rate is controlled so as not to exceed the remaining capacity in the NWI as measured by a level sensor in the NWI. The Basin Compartments 1 and 2 can be dewatered from a basin water level of 99.5 ft down to about 94.75 ft. The basin could be dewatered by gravity down to 90.5 ft (if siphoning); however, at a water surface level below 94.75, the flow rate in the discharge line causes the velocity to drop below a recommended value of 3.5 ft/sec.

The remainder of volume in the basin must be removed by pumping. There are two 8,000 gpm pumps for each basin, for a total of four dewatering pumps. The system was designed for one pump as duty, with the other pump as backup. The dewatering pumps were designed to remove water down to about 74.5 ft, which is about 25 ft below the basin high water level.

The dewatering system originally included one 200 gpm sump pump for each compartment. These pumps have been removed. As noted below, Operators would like to see this pump replaced.

The basin was also designed to be decanted if there was no capacity in the NWI before a subsequent storm. The top 5 ft of water from the basin compartments could be decanted to the Rouge River. There are two decant gates located at the end of Basin 2: Basin Decant Slide Gate and Effluent Decant Gate. The Operators have not decanted flow and do not foresee the need to decant in the future. As such, these gates should remain closed and do not need to be replaced in the future. These gates could be removed in the future and the openings permanently filled with concrete.

Flushing System: The spray flushing system is intended to remove the remaining solids left on the floor of the basin and shunt channel after the basin has been dewatered. There are 22 flushing spray zones. Two submersible flushing water pumps are located in the effluent channel (referred to as the Pond) and a strainer is located in the Process Building dewatering pump room. If there is not enough effluent after a wet weather event in the effluent channel for the basin flushing, additional (City) water can be used to fill the effluent channel. The Pond fills at line pressure and there is no booster pump to help it fill faster.

The flushing system has not performed its intended function since it was originally installed. Solids accumulate across both basins and in the shunt channel. As such, the operators must lower a bobcat into the basin and use fire hoses to clean solids from the bottom of the basin. Due to the extraordinary difficulty of cleaning the basin, GLWA does not clean the basin after every event.

Table 9-7 provides an overview of the existing flushing and dewatering system at Hubbell-Southfield CSO facility.

Table 9-7. Overview of Existing Flushing and Dewatering System at Hubbell-Southfield CSO Facility

Parameter	Value
Total Basin Volume (MG)	22
Headworks and basin Dewatering and Flushing System	- Gravity dewatering can occur for the top portion of captured volume, but this is not typical operation - There are two 8,000 gpm dewatering pumps for Basin 1 and two 8,000 gpm dewatering pumps for Basin 2 - Two 5,000 gpm flushing pumps are located in the effluent channel. A strainer is provided in the Process Building Basement. - Flushing system consists of spray flushing system with 22 zones. System is largely ineffective at removing solids from the basins

9.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- There are significant issues with flushing solids from the floor of the basin and shunt channel.
- The dewatering pumps need to be upgraded and missing sump pumps need to be replaced. A fluidization system should be considered under the sump pumps to avoid large accumulations of solids in the sump
- There is no way to access to the effluent channel (Pond) area.

9.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Basin Flushing System (Project HS-FD-1). Flushing solids from the floor of the basin and shunt channel has been a problem since the facility was constructed. The existing flushing system using spray nozzles has been largely ineffective due to the large volume of solids that are generated during each storm and the fact that a subsequent storm may enter the facility before the entire contents have been cleaned. The configuration of the spray system (15 ft above the floor) also makes the spray system ineffective.

There are three alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Continue Current Operation.** GLWA Operations staff to continue to manually clean the basin.
- 2) **Alternative 2: Contractor Clean Out.** Contractor to manually clean the basin. This alternative is similar to Alternative 1; however, it would include increased number of cleanings per year to meet the intent of the permit to have the basin ready for a subsequent storm event.
- 3) **Alternative 3: New Basin Flushing System.** Based on the poor performance of the existing spray flushing system at Hubbell Southfield and experience at another CSO basin in the Southeast Michigan region (Milk River CSO Basin), GLWA requested a completely new system. Jacobs initially considered both flushing gates and tipping buckets to replace the existing system. After consultations with several manufacturers and evaluating initial conceptual layouts, tipping buckets were removed from consideration due to the low head space inside of the basin areas and maximum flushing length limitation of only 200 ft. As such, the recommended flushing system involves flushing gates/reservoirs in the contact basins and an improved spray system in the shunt channel. This concept is shown in Figure HS-FD-1-ALT-3 in Volume 6 – Appendices, Appendix B.

Demolition. The demolition activities consist primarily of removing of the existing basin mixers and spray system components (pumps, pipes, fittings), concrete removal for construction and permanent access through the roof slab, and other equipment mounted inside of the tank to allow the extensive structural concrete placement. Temporary relocation of some equipment and piping/conduits on top of the tank to facilitate construction is assumed.

Flushing Gate Reservoir Configuration. The existing basin's semi-circular configuration, slope, alignment of the NWI dividing basin into two sections, and drainage channels create a challenging retrofit condition. Flushing gate reservoirs will be located along three lines in the upstream and downstream sections of the two basin compartments. The reservoir volume is determined by the length and slope of the surface that must be flushed by the flushing wave. The longest flushing length is along the northeastern wall of the facility is approximately 430 ft long. The average flushing reservoir volume for the conceptual configuration is approximately 15,000 gallons. The final design should validate and further refine the minimum volume requirement using a sediment fate-transport model (e.g., HEC-RAS) for each flushing lane based on length

and longitudinal channel slope. For 37 flushing reservoirs, the total flushing volume required is approximately 550,000 gallons.

Immediately downstream from the screens, an initial reservoir array will be constructed in Basin 1 with the flushing gate reservoirs suspended above the basin floor and with the gate openings directed towards the existing drainage channel in the upstream section. The suspended reservoirs, as shown in Figure HS-FD-1-ALT-3, allow low flows to continue underneath into the basin in a 2- to 3-foot high channel. As the water level continues to rise in the basin, the hydraulic gradient will build upstream of the suspended reservoirs and increase the velocity in the low-flow channel, effectively moving sediment into the basin sump and the dewatering pump station. Flows will eventually overtop the flushing gate reservoir walls (approximately 8 ft above the floor) and fill the reservoir volume.

A second array of flushing reservoirs is proposed in Basin 2 on the downstream side of the NWI alignment. The reservoirs of this array would be constructed on the existing basin floor with the gate openings directed towards the drainage channel that runs through the middle of Basin 2. The third and final array would be constructed along the finger weirs near the basin outlet. These reservoirs would also be constructed on the floor with the gate openings directed back towards the drainage channel in the middle of Basin 2.

Structural Retrofits. Flushing gates release a flushing wave that needs to be contained in a confined channel to maintain velocity and effectively carry resuspended sediment to a collection point. The basin floors will require concrete training walls along each flushing channel. Additionally, the existing floor will require concrete leveling across most of the entire basin to create level cross-sectional flushing channels. The conceptual design developed indicates that approximately 8,000 cy of concrete fill will be required to create adequate flushing wave channels and reservoirs. Additional concrete fill (structural and low-density concrete fill, approximately 1,000 cy) will be required throughout the basin as fillets and bulk fill to eliminate voids and areas where the flushing waves cannot remove sediment. The total displacement of the new concrete in the contact basin is approximately 1.82 million gallons.

A review of the existing facilities structural details indicate that the base slab could be susceptible to damage if any drainage channel realignments are made. The conceptual design avoids additional base slab structural improvements and subsurface improvements. Additionally, the facility's proximity to surface water and high groundwater would require extensive dewatering should any penetrations through the base slab be required. Additional modifications to the existing base slab, addition of concrete, and other improvements may negatively impact the structure and the foundation. A detailed analysis of the future condition live/dead loads should be completed during final design and structural/foundation improvements incorporated into the project by the final designer. These improvement could include additional piles, retrofitted structural supports, and use of higher strength concrete mixes.

Secondary Flushing Water Source. A secondary source of flushing water is recommended to provide additional flushing cycles for post-event cleaning. The base option for the concept development is to repurpose the existing flushing system water source and install a pipe network to fill the reservoirs in each array. A second option is to use a surface water source, similar to St. Aubin CSO Facility. The close proximity of the Rouge River at the outfall end of the facility allows for the installation of a pump intake, pump system and force main to provide water for a fill pipe network in the contact basin above the reservoirs. GLWA should consider large screens (4-in. bar-type or similar) to prevent floating debris from entering the effluent chamber. GLWA's experience with zebra mussel removal from other facilities in this area indicates that smaller screen openings should be avoided. Similarly, a small opening with a flap-gate opening inward to the effluent channel may help prevent floating debris from entering while ensuring adequate water is available for secondary flushing and shunt channel spray system operation.

The recommended alternative assumes each array of flushing gate reservoirs will be filled using surface water as the flushing water source, similar to the St. Aubin flushing system. Two 2,000-gpm submersible pumps will be mounted in the existing effluent channel. Each pump will discharge to separate 6-in. HDPE force mains that are mounted to the interior roof of the contact basin space (either at the centerline of the overall basin, or

along one wall). One pump will provide flushing water to the northernmost flushing reservoir array, and the other will provide flushing water to the other two arrays. At each array, a second run of 6-in. HDPE will extend over the top of the flushing reservoirs with a tee fitting. A concrete notch (3 ft long by 6 in. deep) cut into the walls between each reservoir would serve as a weir and will enable flows between the reservoirs to fill evenly as the pumps operate.

GLWA has noted that Basin 2 tends to accumulate more solids from wet weather events than Basin 1 and is expected to require more than one post-event flushing with the proposed flushing gate system. By dedicating one pump to the Basin 2 flushing gate arrays (closest to the finger weir), GLWA will be able to more quickly fill these reservoirs to provide a secondary cleaning of this area (estimated fill time at 2,000 gpm of 100 minutes). The other flushing reservoirs in the northern half of the basin will fill more slowly (approximately 180 minutes).

Alternative Gravity Filling System for Basin 2. A sub-alternative for filling the flushing gate reservoirs includes adding a new gated opening or repurposing an existing gated opening in the finger weirs between Basin 2 flushing chamber and the Pond. Each flushing reservoir will have a lower weir notched into the concrete walls between adjacent flushing reservoirs. Opening the gate will allow river water from the reservoir to quickly fill this array of flushing gate reservoirs from one source via overtopping the notched weirs and provide water for additional flushes. A screened and gated opening between the reservoir and the river channel is required to control flows into this space and limit floatable materials and larger aquatic organism from entering the facility. Pumping river water to the other flushing reservoirs using pumps would still be required with the conceptual configuration proposed. Extending a gravity pipe to the other arrays may be possible by adjusting or reconfiguring the elevations and layout of the proposed concept.

New Shunt Channel Flushing System. A new spray flushing system is proposed for the shunt channel. Two new flushing headers will be extended into the shunt channel on both sides of the conduit, and two new submersible pumps will draw river water from the effluent chamber near the secondary flushing gate water source pumps described above.

Each pump will provide water to one half of the shunt channel. Record drawings indicate a transverse slope in the channel's shelf of approximately 0.7 to 1.0 percent, draining from the exterior wall towards the low-flow channel next to the interior wall. The low-flow channel has a slope of approximately 0.5 percent and drains the northern and southern effluent channel sections towards the dewatering pumps. The northern (Basin 1) half of the channel will include two 590-foot, 8-in. HDPE (SDR 13.5) headers, mounted with stainless steel hardware approximately 6 ft from the floor, one above the top edge of the shelf and the other over the low-flow channel. Half-in. holes will be directionally drilled on 4-foot spacings to push solids towards the low flow channel, and along the low-flow channel towards the dewatering pumps. The pumping requirement for the northern half system is approximately 3,300 gpm. The southern (Basin 2) half of the channel includes two 280-foot, 8-in. HDPE headers mounted in a similar fashion and drilled accordingly. The pumping requirement for the southern half system is approximately 1,600 gpm. Similarly-sized pipe runs (approximately 560 ft) connect pumps to both headers.

The control strategy may require only running one half of the effluent channel cleaning system at a time in order to prevent overwhelming the dewatering pumps. Control valves to support pulsing may be required and are recommended to be installed on top of the facility or in new vaults installed in the roof. Flow rate, volume/pressure at application points and control strategy should be confirmed during final design using CFD or scale models.

Additional Mechanical Systems. The flushing gate hydraulic systems will require a new control room as the existing surface facilities at Hubbell Southfield do not have adequate space. Therefore, a new control room/building (occupied, declassified space) is assumed and will be constructed on top of the roof slab. The cost estimate assumes a stand-alone building rather than remodeling or adding to either of the existing buildings. An allowance for structural retrofits of the existing tank's roof slab and beams to support a new

surface structure is included in the costs. Hydraulic tubing would be routed inside of the basin along the ceiling to each gate actuator.

Advantages and Disadvantages of Alternative: This flushing gate option described above appears to be the most viable solution for improving the flushing of the basin using automated systems. The advantages of a flushing gate system at this facility include:

- Effective removal of sediment from the bottom of the basin: Currently, the sediment is only removed periodically due to the significant amount of time and effort. The new system should be able to flush the basins every time the basin is dewatered after a storm event.
- Improved NPDES permit compliance by being able to clean the basin after every event. Note that permit prohibits the discharge of sludge or residual accumulations from the basin to surface waters and requires the settled sludges to be promptly removed and disposed in accordance with procedures approved by EGLE.
- Improved safety for GLWA Operations staff: The flushing system eliminates the need for Operations personnel from entering and operating machinery in the confined space.
- Reduced O&M labor costs for sediment removal compared to current process: Currently, it takes about three personnel about one week to clean the entire basin and occurs about four times per year. This represents a cost of about \$50,000 per year.
- Potential reduction in flushing water usage: The existing spray system uses up to about 7 MG of City water after each event. The proposed flushing water system could eliminate the use of City water if river water can be used as the source of flushing water.
- Some other CSO basins in the area (i.e., Milk River) have removed flushing nozzle systems because they are ineffective.

The disadvantages of this system include:

- High capital cost. The cost estimate for the required modifications to the facility to construct a new flushing gate system is significant.
- Additional systems that require O&M: Adding about 37 flushing gates, hydraulic control system, and secondary flushing water system would add the number of assets that require preventative maintenance and replacement. Secondary flushing system pump operation power requirements would increase the facility's overall electrical consumption.
- New concrete used to construct the flushing system will displace approximately 1.8 million gallons of volume in the contact basin. This will reduce the contact time and may impact the CSO facility's ability to meet regulatory permit requirements. GLWA should assess this impact in more detail during final design of this improvement.
- Difficulty of Construction: Factors that make the construction of the flushing gates difficult include construction of the concrete flushing gates and training walls inside a covered basin, relatively tight site conditions, and the need to keep treating CSO flows. (It is noted that Basin 1 could be completely isolated during construction and allow treatment through Basin 2; however, it is not possible under current configuration to isolate Basin 2 and allow flow to be routed only through Basin 1)

The alternative evaluation for these alternatives is presented in Table 9-8. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 and 2 is based on the replacement cost of the piping and spray nozzle system in about 2014, inflated to 2021 dollars.

- The O&M costs for Alternative 1 includes GLWA labor cost for four cleanouts per year and associated water usage. The labor cost is based on GLWA labor cost of three staff for 40 hours per week and four times per year, or about \$48,000 per year. The water usage is estimated to be 7 MG per clean-out. At \$4,000 per MG, the cost is about \$112,000 per year.
- The O&M costs for Alternative 2 includes assumed Contractor labor cost for 12 cleanouts per year (average of one per month) and associated water usage. The labor cost is assumed to be about \$20,000 per clean-out, or about \$240,000 per year. This cost is an estimated cost to provide reliable cleaning of the basin on a periodic basis. The water usage is estimated to be 7 MG per clean-out. At \$4,000 per MG, the cost is about \$336,000 per year.
- The capital cost for the flushing system (Alternative 3) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 includes \$10,000 for annual maintenance of the new equipment and electricity costs for the river water pumping.

This evaluation shows that Alternative 1 – Continue Current Operation has the lowest NPV/Benefit cost and is shown to be the Best Value Alternative. The poor health and safety conditions for GLWA operations personnel, however, are not properly conveyed in this analysis and the current four cleanings per year is not believed to be adequate to meet EGLE requirements to have the basin ready for subsequent storm events. Using contracted labor would allow GLWA to have the basin cleaned after most storm events; however, the NPV/Benefit cost is higher than Alternative 3. Alternative 3 provides the benefit of improved health and safety by not having to enter the basin for cleaning, and it is easily operated by the O&M staff after every storm. The Total Benefit score for Alternative 3 is about 2.0 points higher than Alternative 2. **As such, Alternative 3 – New Basin Flushing System is the recommended alternative.**

Table 9-8. Alternative Evaluation for Basin Flushing System (Project HS-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	5						

Dewatering and Sump Pump Improvements (Project HS-FD-2). Sump pumps for Basin 1 and 2 were originally installed next to the basin dewatering pumps. Due to the large accumulations of solids in the sump, these pumps were routinely overwhelmed with solids. As such, O&M staff have removed them from both basins, but they indicated these pumps are beneficial for proper flushing and removal of solids.

There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Replace In-Kind.** Replace the dewatering and sump pumps in-kind.
- 2) **Alternative 2: Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System.** Two new 200 gpm, sump pumps should be installed. It is recommended that a solids fluidization system be installed under the intake of the new sump pumps and the dewatering pumps. This fluidization system could consist of a water jet to fluidize the accumulated grit before the pump turns on. The project should also provide a new base elbow, cleaning of the discharge pipes, replacement of valves on the discharge line, and replacement of the pump rail system.

O&M staff also requested that the type of dewatering pump be investigated to ones that better handle heavy grit loads. The existing four pumps are manufactured by Vaughan. The N-Series submersible pump by Flygt has replaced a number of dewatering pumps at other CSO facilities and are recommended at this location. Based on input from Kennedy Industries, a Flygt Model NP-3202 would be an appropriate replacement pump. The preliminary sizing indicated that these pumps have a slightly lower horsepower than the existing pumps. Detailed design is needed to confirm pump sizing. The elevation of each dewatering pumps should also be investigated (consider one higher than the other to avoid the heavy grit loads).

This project should be incorporated into the flushing gate project (Project HS-FD-1), if the new basin flushing system moves forward.

The alternative evaluation for these alternatives is presented in Table 9-9. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 is based on the pump replacement costs from the SRP.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title. It includes a new fluidizing system to allow the sump pumps to function properly. It also includes new piping to replace the existing and allow the pump elevations to be modified.

Alternative 1 is shown as the Best Value Alternative. The scope of Alternative 2 is generally similar to Alternative 1; however, there are additional improvements in Alternative 2 that are necessary to allow the system to function properly. As such, **Alternative 2 - Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System is the recommended alternative.**

Table 9-9. Alternative Evaluation for Dewatering and Sump Pump Improvements (Project HS-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Disadv.:</i>	None.	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Effluent Channel (Project HS-FD-3). There is no manned access to the effluent channel area (i.e., the area between the effluent weirs and the effluent flap-gates). GLWA needs to access this area to allow equipment to be lowered into this space for removal of settled solids from the floor.

There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing**
- 2) **Alternative 2: Equipment Access to Effluent Channel.** A hatched opening is desired for this area in a location shown in Figure HS-FD-3-ALT-2 in Volume 6 – Appendices, Appendix B. One option is to cut an opening in one pre-stressed concrete plank and use removable covers, similar to the existing hatch shown in the photos in the Appendix. Another option that should be considered during design is providing an aluminum hatch opening, so that a boom truck is not needed to remove the cover.

This project should be incorporated into the flushing gate project (Project HS-FD-1), if the new basin flushing system moves forward.

The alternative evaluation for these alternatives is presented in Table 9-10. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to need to access this location for solids clean-out, **Alternative 2 - Equipment Access to Effluent Channel is recommended.**

Table 9-10. Alternative Evaluation for Access to Effluent Channel (Project HS-FD-3)

9.2.5 HVAC

9.2.5.1 Description of Existing System

The Hubbell-Southfield CSO Facility consists of a Headworks Building and a Process Building. The buildings contain a Headworks area, chemical room, utility support (electrical and mechanical rooms), control room, odor control rooms and other miscellaneous rooms. The facility also includes a retention basin. Table 9-11 provides a summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, emergency shower/eye wash and washroom regular shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 9.2.10.

Table 9-11. Major HVAC Equipment at Hubbell-Southfield CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-3	Heating Ventilating Unit	25,000 CFM
Basin 1	SF-1 to 6	6 × Supply Fans	50,000 CFM
Basin 2	SF-7 to 13	7 × Supply Fans	50,000 CFM
Chemical Room (Headworks Bldg)	EF-2	Exhaust Fan (Hypochlorite Rm)	2,200 CFM
	HVU-2	Heating Ventilating Unit	10,500 CFM
Process Control Bldg	PACU-1	Packaged Air Conditioning Unit	3,400 CFM

Note:

HVU = Heating Ventilation Unit

Table 9-12 provides a summary of the basis of design performance criteria for HVAC systems at Hubbell-Southfield and Table 9-13 provides the outdoor Basis of Design conditions.

Table 9-12. Hubbell-Southfield Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Odor Control Room – Process Building	Unclassified (Per As-Built Drawings)	70	N/A	12 ACH
Work Area, Electric Room, Toilet, Storage, etc., – Process Building	Unclassified	70 (Occupied) 60 (Unoccupied)	78	6 ACH

9.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- Heating in the dewatering room (basement of Process Building) was reported to be insufficient. No freezing of pipes was reported.
Jacobs further investigated this issue through review of design information and site visit. All spaces in the Process Building have a basis of design winter dry bulb temperature of 70°F. The dewatering room's HVU duct heater has a design capacity of 125,000 Btu/h which should be sufficient to heat the dewatering room to 70°F using 80 percent return air, as designed. EF-7 was not observed to be operating. Given the significant amount of corrosion that was observed on EF-7's motorized damper, it is very likely that the damper is seized. This could not be verified in the field due to the inaccessible location of the damper. The observed cold air temperatures in the dewatering room are most likely the result of HVU-4's outside air supply damper remaining fully open during heating mode and/or the return air damper remaining in its minimum position. Given the age of the equipment serving the dewatering room, a replacement in-kind of HVU-4, EF-7 and associated supply, return, and exhaust dampers is recommended and should resolve this issue. This project will come from the SRP.
- O&M staff requested that air conditioning in the Process Building odor control room. Upon further discussion, the main activity routinely performed in this area is sample preparation and analysis. Instead of air conditioning the entire odor control room, it was recommended to move the sample sink to the work area, which is already air conditioned. This is currently an on-going project to be completed by GLWA maintenance staff
- Heating and cooling issues in Process Building. Staff reported that improvements were needed.
- Historical Issues with Heating and Ventilation Units: GLWA's HVAC contractor noted there had been issues with the HVUs which had been resolved. They did not note any out of the ordinary wear or capacity issues with the units.

During Jacobs site investigations (June 2020) the following observations were noted:

- It was observed during the site visit that the air balance of PACU-1 in the Process Building had been adjusted since installation. It is very likely that this adjustment came from a desire to improve thermal comfort in occupied spaces. Additionally, it was noted that the supply air duct from PACU-1 runs from the West side to the East side of the Process Building; however, the return air duct terminates at the entrance to the odor control room (see Figure 9-2 below). This is likely to result in poor air quality as a result of a lack of air circulation in spaces on the East side of the Process Building.

Figure 9-2. PACU-1 Return Air Ductwork

- The doors between the Process Building odor control room and the Work Area were observed to be open. Additionally, ventilation in the odor control room was switched off. Condensation was noted on the PACU-1 supply air duct directly in front of the Odor Control Room.
- Condensation was noted on the floor at the top of the dewatering room (basement) stairway. HVU-4, which serves the dewatering room was supplying ventilation air but EF-7 which provides relief for the air supplied to the dewatering room was not operating despite having its motorized damper in the open position. Additionally, significant corrosion was observed on the body of the dewatering room's duct mounted gas furnace (Figure 9-3).

Figure 9-3. Corrosion on EF-7 Ductwork

- HVU-2's supply fan, which provides ventilation to the odor control room in the Headworks Building, was observed to be running; however, EF-1, EF-2, EF-3 were not operating.

9.2.5.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Process Building Air Balance Study. An air balance is recommended for the Process Building to determine if the heating and cooling issues are the result of a poorly balanced system. It is noted that the operators occasionally leave the door to the odor control room open to cool this area, as observed during the site visit. This may be contributing to the issues related to poor cooling provided by PACU-1. Also, it should be noted that the spaces in the Process Building which are cooled are only designed to be cooled to 78°F.

If the air balance does not improve conditions in the Process Building, extending the return air to PACU-1 should be considered. This should improve air circulation and increase supply air flow to the spaces on the East side of the facility, including the Office.

Scheduled Replacement Plan: As noted in Section 9.2.5.2, many of the relatively small HVAC-related equipment at this facility is recommended to be replaced in-kind. Therefore, it is included in the SRP.

9.2.6 Electrical

9.2.6.1 Description of Existing System

The Hubbell Southfield facility's electrical system consists of one DTE utility feed from a 1,500 kVA, 480 V, 3-phase outdoor transformer (secondary metering) and one diesel generator feed from a 600 kW, 480 V, 3-phase stationary generator. The feeds are connected to a 2,500 A switchboard MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP switchboard also has a 2,000 A breaker before the ATS, which feeds a main circuit breaker panel switchboard (MCBP). The MDP and MCBP have breakers that

feed motor control centers (MCCs) and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 9-14 provides a summary of the major electrical equipment for this facility.

Table 9-14. Major Electrical Equipment at Hubbell-Southfield

Location	Major Electrical Equipment	Description
Electrical Room	Main Switchboard/ATS (MDP)	2,500 A, 480/277 V, 3-Phase
Outdoors	Generator (Diesel)	600 kW, 480 V, 3-Phase
Electrical Room	MCC-P1	600 A, 480/277 V, 3-Phase
Odor Control Room	MCC-H1	250 A, 480/277 V, 3-Phase
Electrical Room	MCC-P2	1,200 A, 480/277 V, 3-Phase
Odor Control Room	MCC-H2	600 A, 480/277 V, 3-Phase

9.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the next section.

9.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project HS-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating at night and select locations within the basin.
- 2) **Alternative 2: Electrical Improvements.** Add Lighting and Exterior Power Receptacles at the following locations (and shown on the electrical drawings - Figure HS-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin Nos. 1 and 2—Add interior explosion-proof LED lighting fixtures to provide lighting within the basins.
 - Access road—Add light poles and associated LED light fixtures. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - Outfall area—Add a light pole and overhead lighting at the facility's outfall. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - External lighting on top of Basins—Add light poles and LED lighting fixtures on the facility's basins. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including receptacles every 75 ft on top of the basins for maintenance and operational needs.

This project should be incorporated into the flushing gate project (Project HS-FD-1,) if the new basin flushing system moves forward because of the amount of work on and in the basins.

The alternative evaluation is presented in Table 9-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$100,000, which is a moderate cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 9-15. Alternative Evaluation for Electrical Improvements (Project HS-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night and when accessing select locations within the basin.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 349,000	\$ -	\$ 349,000	\$ 99,714	Not Applicable
	<i>Definition:</i>	Add additional lighting and receptacles at identified locations	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.7 I&C

9.2.7.1 Description of Existing System

Control System: The original control system at Hubbell Southfield was installed in 1996 under PC-694. Since then, several modifications to the original control system have taken place. In 2002 under PC-713, the facility's PLC control system was upgraded to interface with the Ovation system to enable remote monitoring and control the facility from SCC. In 2009, PC-761 replaced the control system and workstations with new Allen Bradley ControlLogix redundant PLCs and new operator workstations with Factory Talk View SE software. The existing hardwired back-up control panel and other miscellaneous PLCs and subsystems are incorporated into the overall control system. The current system is equipped with a back-up radio system to communicate critical monitoring points back to the SCC on wide area network failure.

The current PLC control system and back-up panels are obsolete and do not meet GLWA SCADA Governance standards, which stipulate that all CSO facilities use Ovation workstations with high-performance graphics.

Flow and Level Sensors: Table 9-16 summarizes the level sensors and flow meters at the Hubbell-Southfield CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 9-16. Summary of Flow Meters and Level Sensors at Hubbell-Southfield CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent channel (Upstream of inflatable dams)	2	Transit-Time (AccuSonic)
Shunt Channel (Shunt and bypass)	2	Transit-Time (AccuSonic)
Dewatering Flow	1	Magnetic
CSO Facility Level Sensors		
Influent channel (Upstream of inflatable dams)	2	Ultrasonic
Shunt Channel (Shunt and bypass)	2	Ultrasonic
Screening area (upstream and downstream of bar racks)	2	Ultrasonic
Basins	2	Ultrasonic
Dewatering Wells	2	Ultrasonic
Effluent Channel	1	Ultrasonic
Rouge River	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed	1	Ultrasonic

9.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Evaluate level sensors and flow meters to determine redundancy and identify sensors or meters that could potentially be removed. Jacobs further evaluated this issue and found that the flow meter in the Shunt Channel is redundant to the flow meters for the Bypass Channel and Influent Channel and could possibly be eliminated. Under the current operation of first flush capture, the Shunt Channel flow meter provides the flow

rate for flow to Basin 2 (after Basin 1 is full) and flow to the Bypass Channel (when the Bypass gates are open). Since there is a flow meter on the influent and one on the Bypass, the Shunt Channel flow meter is redundant and could be removed. However, it does provide redundancy if the Influent flow meter fails and it was recently replaced. It is recommended that the Shunt Channel flow meter be considered for elimination when it is near the end of its useful life.

- Need for remote control capability of the Chemical Feed area from the Control Building
- Need for remote control of VR-8 gate. This need is scheduled to be addressed in Spring 2021 by SCC under CS-090A. This project will provide remote control of this gate from either the Hubbell Southfield CSO Basin or SCC.
- Need for local remote control for dewatering pumps
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system to the latest version and increased monitoring capabilities

9.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project HS-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, all of the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements** including,

- Provide remote control capability of the Chemical Feed area from the Control Building
- Provide local remote control for dewatering pumps
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Provide remote control capability of the Chemical Feed area from the Control Building. A Remote I/O panel will be required at the Chemical Feed area which will be connected to the Control Building via a fiber optic cable. The Remote I/O panel will interface with the existing motor starter control circuits to be able to operate the equipment remotely.

Provide local remote control for dewatering pumps. Provide local control for the four Dewatering Pumps in accordance with Section 5.4.9.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 9-17. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – I&C Improvements has a total benefit score about 0.3 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M provided by the various I&C improvements. The NPV/Benefit cost for Alternative 2 is \$120,000, which is a moderate cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 9-17. Alternative Evaluation for I&C Improvements (Project HS-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 274,000	\$ 7,000	\$ 421,627	\$ 127,124	Not Applicable
	<i>Definition:</i>	Provide local control capability of the Chemical Feed area from the Control Building; provide local remote control for dewatering pumps; provide tank level indication at Chemical Fill Station; provide process cameras at select locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Control System Upgrade (Project HS-I&C-2). The current facility's PLC control system, network, workstations and control system back-up panels are obsolete and should be replaced in the near future. The control system does not meet GLWA SCADA Governance standards, which require that all CSO facilities use Ovation workstations with new high-performance graphics. GLWA's standards for local CSO facility's control systems can be either the latest Allen Bradley PLC system with Ovation workstations or a complete Ovation system. This approach is being used on an ongoing project at Leib, Seven Mile, and St. Aubin.

Because of the approach used on the ongoing project, there is only one overall control system alternative considered. The project should include decommissioning and removal of the original hardwired back-up local control panels. These local panels are no longer required with today's redundant control system processors and local Operator Interface Terminal (OIT) as local back-up to the facility's workstations.

Table 9-18 provides the summary of the **Control System Upgrade, which is the recommended alternative**. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Consideration should be given to replacing various field instruments; however, these are not included in the capital costs.

Table 9-18. Alternative Evaluation for Control System Upgrade (Project HS-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 2,457,000	\$ -	\$ 2,457,000	\$ 819,000	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.8 Site

9.2.8.1 Description of Existing Site

The Hubbell-Southfield CSO Facility was constructed in 1994. The Hubbell-Southfield facility has two buildings situated on top of the basin, namely the Headworks Building over the north influent end of the basin and the Process Building over the dewatering pumps at the center of the basin. The access entrance to the site is through a 24-ft wide sliding vehicular gate. Security around the perimeter of the site is provide by an 8-ft high chain link fence. Site pavement consists of 9-in. reinforced concrete on undisturbed earth. There are no sidewalks near the basin. The access road from Rotunda Dr. to the basin consists of 10-in. asphalt on 12 in. of gravel base.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

9.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- The existing 2-in NPW header line for flushing the basins provides insufficient pressure for washdown after storm event.
- Poor condition of the service drive around the basin
- Localized ponding of water on the basin surface. In the winter, this water freezes and causes safety concerns
- Poor condition of security fencing
- The detention ponds drainage from the gold course discharged over the access road creates an issue for GLWA vehicles driving through
- The following needs are generally preventative maintenance items intended to ensure that the site features or utilities are serviceable throughout their expected service lives.
 - Remove vegetation from the fence line around the perimeter of the basin
 - Re-caulk expansion joints at the base of the exterior walls around the Headworks and Control Buildings
 - Replace expansion joint membranes and expansion joint cover plates on the basin service drive.

9.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing Water Pressure in Headworks Area (Project HS-Site-1). A 6-in. watermain services the Headworks Building and supplies the NPW service to the hose bibs in the basin. The 6-in. watermain is tapped from an 8-in. watermain outside of Headworks Building. The NPW is supplied through a 2-in. header that runs through the length of the basin with drop connections at hose bibs spaced approximately 100 ft apart. GLWA Operations staff

indicate that there is little pressure in the 2-in. NPW line for hose washdown inside the basin after a storm event. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area.** To increase pressure in the NPW line, it is recommended to demolish and replace approximately 950-ft of the existing 2-in. header in the basin with a 4-in. header (See Figures HS-SITE-1-ALT-2). The size of this header should be confirmed during detailed design.

The alternative evaluation is presented in Table 9-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$33,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area, is the recommended alternative.**

Table 9-19. Alternative Evaluation for Flushing Water Pressure in Headworks Area (Project HS-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Insufficient water pressure for washdown after storm event.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	Health and Safety	3	3.42	\$ 112,000	\$ -	\$ 112,000	\$ 32,780	Not Applicable
	<i>Definition:</i>	To increase the pressure in the non-potable water line, it is recommended to replace the existing 2" header with a 4" header in the basin.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier washdown	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Site Improvements (Project HS-SITE-2). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Resurface Service Drive Around Basin
 - Improve Basin Roof Surface Drainage
 - Replace Security Fencing
 - Culvert for Golf Course Drainage

Each of the site related improvements listed above are described further below:

Resurface Service Drive Around Basin: The existing service drive around the basin is in poor condition. The service drive along the east side of the basin consists of reinforced concrete slab, which is the roof of the Dearborn Channel and Shunt Channel. The remaining portion of the service drive that runs across the basin and then along the west side of the basin to the headworks building consists of 4-in. concrete topping reinforced with welded wire fabric (WWF) on top of double tee beams of the basin roof.

To restore the service drive along the east side, it is recommended to hydro-demolish the top surface of the Dearborn and Shunt Channels roof slab up to 2 in. below the top layer of reinforcement and reconstruct the slab. To restore the service drive across the basin and along the west side of the basin, it is recommended to hydro-demolish the entire 4-in. thick concrete topping and replace it with new air entrained reinforced concrete topping. The reconstruction of the slab along the east and west sides of the service drive should be sloped to provide drainage away from the structure and towards grassy areas.

It is noted that the hydro-demolition and reconstruction activities will require a temporary support system from below to maintain the integrity of existing structural systems (roof slab/double Tees) during construction activities. Representative concrete core samples should be taken and tested by a material testing company to check the integrity of the slabs prior to any demolition activities.

Improve Basin Roof Surface Drainage: There are numerous areas on the basin roof surface where localized ponding of water occurs (See Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B). Ponding of water can become a safety issue for personnel who must navigate around these areas to access equipment or facilities during winter months when the surfaces turn to ice. It is recommended at the larger areas of ponding water that cores be made through the basin roof to drain the area. Recessed plaza deck drains should be installed in the cored holes to drain ponded water directly to the basin. As an alternative, to prevent stormwater from entering the basin, consideration could be given to piping the ponded water drainage on the underside of the basin through the basin exterior walls and discharge to drainage swales on either side of the basin. It is estimated that there are 10 to 15 significant sites of ponded water on the basin surface.

Replace Security Fencing: There are two locations where fencing needs to be replaced because it is in disrepair:

- The fencing at the entrance to the service drive from Rotunda Drive (see Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B, for location). The fencing extends on the south side of the service road from Rotunda Drive to the gate on the service drive at the Tournament Players Club golf course maintenance building. This includes 360 ft of 5-ft tall cyclone fencing.
- The fencing on the north side of the access road from Rotunda Drive to the facility access gate (also shown in Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B). This includes approximately 2,300 ft of 5-ft tall cyclone fencing.

It should be noted that the as-built drawings for this facility (PC-694) do not include fencing. As such, it appears the fencing was existing when the facility was built and may not be the responsibility of GLWA.

Culvert for Golf Course Drainage: Periodically, the Tournament Players Club golf course must drain detention ponds located on the course. This is generally accomplished by pumping pond contents through hoses and discharging over the access road to allow the water to drain to the Rouge River. To minimize soil erosion from this method of pumping, GLWA has proposed to create a drainage culvert beneath the access road so that the pond water can be discharged beneath the road rather than across its surface where it is tracked by GLWA vehicles. The new drain should be located beneath the access road in the vicinity of the Tournament Players Club Maintenance Building and should include a catch basin on the north side of the road and a rip rapped discharge with a headwall (or spillway) on the Rouge River side of the access road.

The alternative evaluation is presented in Table 9-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety, and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$258,000. **Because of the improved drainage and safety and restoration of the road with Alternative 2 – Site Improvements, Alternative 2 is the recommended alternative.**

Table 9-20. Alternative Evaluation for Site Improvements (Project HS-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 902,000	\$ -	\$ 902,000	\$ 257,714	Not Applicable
	<i>Definition:</i>	Resurface Service Drive Around Basin; improve basin roof surface drainage; replace security fencing; culvert for Golf Course drainage	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved drainage & improved safety for accessing facility.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.9 Architectural

9.2.9.1 Description of Existing Facilities

The Hubbell-Southfield CSO Facility consists of Headworks Building and Process Building. The Headworks Building includes a screen room, chemical room, a mechanical room and an odor control room. The Process Building includes a control room, utility support (electrical and mechanical), odor control room, and other miscellaneous rooms. The facility also includes the retention basin.

9.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 9-21. As such, the roof should be replaced in-kind and the costs and schedule for the roof replacement will come from the SRP.

Table 9-21. 60-Year Life Cycle Cost Evaluation of Shingled vs. Metal Roof for Hubbell-Southfield Facility

	Shingle Roof	Metal Roof
Replacement Cost ¹	\$282,000	\$940,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life Cycle Cost (NPV) Discounted at 2.4%	\$766,000	\$940,000

¹ Based on 18,800 ft² roof area; \$15 ft² for shingle roof and \$50/ft² for metal roof.

CS-299 Architectural Assessment: Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

9.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (HS-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Install floor expansion joint in Process Building
 - Paint wood truss and plywood roof deck in Process Building
 - Remove corrosion on bollards, and clean and coat
 - Remove existing paint, clean and paint wood roof deck and framing
 - Install vertical expansion joint and repair concrete and wall in Headworks Building
 - Replace damaged/stained/missing acoustic ceiling tiles in Process Building
 - Address door hardware issues
 - Caulk gap of fascia board on Process Building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure HS-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 9-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 9-22. Alternative Evaluation for Architectural Rehabilitation (Project HS-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 371,000	\$ -	\$ 371,000	\$ 119,677	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.10 Safety

9.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

9.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 9-23. The capital improvement project to address these issues is included in the table.

Table 9-23. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Headworks	Mid-rail missing between bar screen 2 and 3	Add mid rail	Safety Improvements (Project HS-SAFE-1)
Basin Odor Control Room	At top of ladders, mid-rail chain needed	Add swing gate (original recommendation was to add chain; however, this is no longer current GLWA practice)	Safety Improvements (Project HS-SAFE-1)
Process Building Odor Control Room	Eyewash 0922552 too low	Adjust height of eyewash	Eyewash/Shower Improvements (Project HS-SAFE-1)
Basin Odor Control Room	Eyewash 0947279 too low	Adjust height of eyewash	Eyewash/Shower Improvements (Project HS-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project HS-SAFE-1)

9.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project HS-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing between bar screen #2 and #3 to eliminate fall hazard
- Add swing gate at top of ladders in the basin odor control room
- Adjust height of eyewash in the Process Building odor control room and basin odor control room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 9-24 shows the one alternative.

Table 9-24. Alternative Evaluation for Safety Improvements (Project HS-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 158,000	\$ -	\$ 158,000	\$ 41,762	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.11 Supporting Infrastructure

9.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

9.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- The VR-8 Regulator upstream of the Hubbell-Southfield CSO Facility is located in the center median of Michigan Avenue east of the Southfield Freeway. The VR-8 Regulator consists of two stainless steel slide gates that are adjusted by SCADA control to regulate flow from the Hubbell-Southfield sewer to the NWI. A rehabilitation project was designed in 2013 by Metco, but not implemented. Rehabilitation of the VR-8 Regulator is still needed. It should be noted that the control system for the regulator is being upgraded in early 2021 under Project No. CS-090A. This upgrade will provide remote control of the two regulator gates from the Hubbell Southfield CSO Facility or SCC.

9.2.11.3 Discussion and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

VR-8 Regulator Rehabilitation (Project HS-SUPP-1). As described in the 2013 Final Basis of Design Report by Metco, the rehabilitation of the VR-8 Regulator included 1) Replacement of the slide gates and actuator; 2) SCADA system modifications; and 3) Access improvements in the median near the gates and control panel. As noted above, the SCADA system modifications are being addressed as part of a control system project. As such, Jacobs based the proposed rehabilitation on the cost estimate generated for this project (inflated to current dollars), excluding the SCADA system improvements. It was noted in the Metco report that the access improvements using geoblock units had not been approved by the Michigan Department of Transportation. These details would need to be resolved during detailed design.

The alternative evaluation is presented in Table 9-25. The capital cost is included in Volume 6 – Appendices, Appendix C under this project title. Since this is rehabilitation of an existing system, there is only one alternative considered. As such, **Alternative 1 is the recommended alternative.**

Table 9-25. Alternative Evaluation for VR-8 Regulator Rehabilitation (Project HS-SUPP-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	VR-8 Regulator Rehabilitation	Health and Safety	3	3.00	\$ 1,956,000	\$ -	\$ 1,956,000	\$ 652,000	Best Value Alternative
	<i>Definition:</i>	Replacement of the slide gates and actuator; and access improvements in the median.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Maintains system reliability and functionality.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Hubbell Southfield CSO facility, Table 9-26 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 9-26, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 9-26. Listing of Asset Condition Assessments for Hubbell Southfield Facility

Asset Type	Total No. of Assets in Asset Type	# of Visual Condition Assessments	# of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset. Another one of the building asset listed as "PLANNING - ORDERING PARTS/FILLING OUT WORK ORDER/COMPLETING INVENTORY OF PARTS ON HAND. (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is also not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Two pumps are listed in WAM - Basin 1 Sample Pump and Shunt Channel Sample Pump. These umps are being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Hubbell-Southfield Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

9.3 Capital Planning for Hubbell-Southfield CSO Facility

9.3.1 Summary of Capital Improvement Plan Projects

Table 9-27 provides a summary of the recommended CIP projects and associated capital costs for the Hubbell Southfield CSO facility based on the alternative evaluations conducted for this facility.

Table 9-27. Summary of Recommended Projects at Hubbell-Southfield CSO Facility

Project No.	Alternative	Description	Total Project Cost
HS-SCR-1	2	Screening Improvements	\$ 195,000
HS-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 534,000
HS-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
HS-DIS-3	2	Add a New Chemical Storage Tank	\$ 753,000
HS-FD-1	3	New Basin Flushing System	\$ 24,800,000
HS-FD-2	2	Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System	\$ 950,000
HS-FD-3	2	Provide Equipment Access to Effluent Channel	\$ 126,000
HS-ELEC-1	2	Electrical Improvements	\$ 349,000
HS-I&C-1	2	I&C Improvements	\$ 274,000
HS-I&C-2	1	Control System Upgrade	\$ 2,457,000
HS-HVAC	N/A	Process Building Air Balance Study	\$ 5,000
HS-SITE-1	2	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	\$ 112,000
HS-SITE-2	2	Site Improvements	\$ 902,000
HS-ARCH-1	2	Architectural Rehabilitation	\$ 371,000
HS-SAFE-1	1	Safety Improvements	\$ 158,000
HS-SUPP-1	1	VR-8 Regulator Rehabilitation	\$ 1,956,000

9.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 9-28. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 9-28. Capital Improvement Plan Projects for Hubbell-Southfield CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
HS-1 Disinfection System Improvements	\$ 1,507,000	2029 <i>Timing based on asset condition</i>	HS-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 534,000
			HS-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
			HS-DIS-3	Add a New Chemical Storage Tank	\$ 753,000
HS-2 Flushing System Improvements	\$ 27,239,000	2026 <i>Timing based on safety issues</i>	HS-FD-1	New Basin Flushing System	\$ 24,800,000
			HS-FD-2	Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System	\$ 950,000
			HS-FD-3	Provide Equipment Access to Effluent Channel	\$ 126,000
			HS-ELEC-1	Electrical Improvements ^a	\$ 349,000
			HS-SITE-1	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	\$ 112,000
			HS-SITE-2	Site Improvements ^b	\$ 902,000
HS-3 Facility-Wide I&C Improvements	\$ 2,731,000	2029 <i>Timing based on asset condition</i>	HS-I&C-1	I&C Improvements	\$ 274,000
			HS-I&C-2	Control System Upgrade	\$ 2,457,000
HS-4 VR-8 Regulator Rehabilitation	\$ 1,956,000	2030 <i>Timing based on best judgment</i>	HS-SUPP-1	VR-8 Regulator Rehabilitation	\$ 1,956,000
HS-5 Facility-Wide Safety and Architectural Improvements	\$ 529,000	2023 <i>Project should be initiated as soon as possible</i>	HS-ARCH-1	Architectural Rehabilitation	\$ 371,000
			HS-SAFE-1	Safety Improvements	\$ 158,000

Notes:

^a Electrical Improvements were combined with Flushing System Improvements because most of electrical improvements are related to lighting within and on top of basin.^b Site Improvements were combined with Flushing System Improvements because road around basin will likely need to be repaired after construction.

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 9-29 and Table 9-30 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 9-29 indicates that HS-DIS-1 project has 12 assets that has an average condition score of 1.57 and an average replacement date of 2029. This information was used to propose a scheduled construction completion date of 2029.

Table 9-29. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
HS-DIS-1	12	1.57	1.57	2.86	12	2029	\$ 969,900
HS-FD-2	3	1.57	1.20	2.51	20	2039	\$ 302,100
HS-I&C-1	4	1.14	1.23	1.85	14	2033	\$ 447,179
HS-I&C-2	3	2.29	1.57	4.08	12	2029	\$ 1,481,175

Table 9-30. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
HS-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
HS-FD-2	3	1.38	5.00	4.83	20	2021	\$ 126,900
HS-I&C-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
HS-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -

There is a recommended capital improvement project presented in Table 9-28 that could be better delivered under capital outlay projects. This project is listed in the following bullet:

- Screening Improvements (HS-SCR-1)

9.3.3 20-Year Capital Outlay Plan

Table 9-31 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 9-31. 20-Year Capital Outlay Plan for Hubbell-Southfield CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Influent slide gate (ISG-2) received a score of 5 at the time of the Condition Assessment since the actuator was on the ground and not mounted to the gate.
- Pumping System: Flushing Water Pump (FWP-2; \$327,000) received a score of 5 since the unit was out of service at the time of the Condition Assessment. Dewatering Pump No. 4 (\$100,700) was not functional during electrical testing at the time of the assessment. The two immersible sump pumps (ISMP-1 and 2; \$13,100 each) have been removed from service for some time.

10. Leib CSO Control Facility

10.1 General Facility Description and Future Capacity Considerations

10.1.1 General Facility Description

The Leib CSO Facility is an SDF with 9.9 MG of storage, and a treatment capacity of 1,550 cfs. It was constructed in 2002. The facility has a nearly 1-mile long effluent conduit used for disinfection contact time before discharge into the Detroit River. The facility consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground outfall vault.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

10.1.2 Future Capacity Considerations

The WWMP recommended projects to increase wet weather flows to existing CSO facilities to maximize the use of the facilities and minimize the construction of additional facilities. Many of the CSO facilities do not reach their design flows, so there is an ability to accept additional flows, without exceeding their design capacity.

The Meldrum Diversion Sewer to the Leib CSO Facility is one of the recommended projects from the WWMP that will increase flows to the existing Leib CSO facility. The magnitude of the increased flows and the potential impact on screening and disinfection performance is described below.

This project originated from the WWMP and involves diverting the Meldrum sewer to the Leib CSO facility by constructing 350 ft of 5-ft diameter diversion sewer along Waterloo just upstream of the Leib facility. See Figure 10-1 for the layout of this new diversion sewer. The Leib CSO facility was designed to treat 1,550 cfs and hydraulically pass 2,000 cfs. The design hydraulic grade line (HGL) conditions are between elevation 110.5 and 111.5 ft, with a peak hydraulic capacity of 2,000 cfs, and a Toward Treatment Sewer capacity limited to 150 cfs.

Figure 10-1. Layout of Proposed Meldrum Sewer Diversion near the Leib CSO Facility

The Regional Wastewater Collection System Model was used during the WWMP to predict the change in hydraulic grade line for the Leib facility for the 10-year 24-hour storm event. The WWMP reports that the 10-year 24-hour storm will add a peak flow of 427 cfs, and the HGL within the Leib CSO facility will stay within the critical elevation of El 589.72 (109.97 Detroit datum) at the crown of the Conant Mt. Elliot Sewer.

10.2 Facility Assessment

10.2.1 Screening

10.2.1.1 Description of Existing System

The Leib CSO Facility has two types of screens: 1) raked horizontal bar screen (original manufactured by COPA) and 2) raked vertical bar screens (manufactured by ROMAG). Constructed in 2002, the facility was intended to be a full-scale pilot facility for this type of fine screen. There are four screening channels in the facility, with a total of eight COPA screens and a total of four ROMAG screens.

During dry weather, raw sewage is routed through the facility and to the Toward Treatment Sewer. During wet weather events, the flow increases, and the flow enters the screening channels as the wet weather flow exceeds the capacity of the Toward Treatment Sewer.

Screenings are retained in the screening channels during the storm. After the storm event, the screenings are conveyed to the Toward Treatment Sewer and then the DRI for eventual removal at the WRRF.

The COPA screens recently received a complete overhaul in 2019. The existing ROMAG screens were also rebuilt in 2019; however, the control panels and power packs were not upgraded.

Table 10-1 provides an overview of the existing screening system at Leib CSO facility.

Table 10-1. Overview of Existing Screening System Leib CSO Facility

Parameter	Value	
Treatment Capacity (cfs)	1,550	
No. of Screens	4 (2 in each of 2 channels)	8 (4 in each of 2 channels)
Manufacturer	Westech ROMAG	COPA
Screen Type	Raked Vertical Bar Screen	Raked Horizontal Bar Screen
Opening Size	4-mm spacing	4-mm spacing
Depth or Length	29 ft 6 in	17 ft 0 in
Width	4 ft 0 in	4 ft 0 in
Screen Cleaning	Mechanical Comb	Mechanical Comb
Screening Removal	Conveyed to Toward Treatment Sewer and then to WRRF	

10.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- ROMAG screens are preferred over COPA for future screens: The screens at the facility are a combination of ROMAG vertical screens and COPA horizontal screens. Having dissimilar maintenance and operating characteristics presents a challenge for the GLWA O&M staff. In consideration that this facility was intended to be a "pilot" facility testing different technologies, it is reasonable to conclude, as it approaches 20-years in age, that some technologies should win out over others. In the case of the screens, the ROMAG screens present the simpler and easier O&M characteristics and therefore standardizing on these screens at this time, when major maintenance or rehabilitation is in the future for both screens, makes sense.
- The ROMAG screens offer a hydraulic benefit of allowing peak flows to overflow the top of the screen (this is not possible with the COPA screens). Although the portion that overflows does not receive screening, it does provide a hydraulic bypass for peak flows so that the screens are not overloaded or damaged. This is an important feature with the addition of the Meldrum Diversion Sewer in the near future.

10.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Screen Replacement (Project LEIB-SCR-1). The ROMAG screens present the simpler and easier O&M characteristics and therefore standardizing on these screens at this time makes sense. There are two alternatives with this option:

- Alternative 1: Replace Existing COPA Screens In-Kind.** This alternative would replace the existing eight COPA screens in-kind.

2) **Alternative 2: Replace Existing Screens with ROMAG Screens.** This project would replace the existing eight COPA screens with four ROMAG screens (Model RSW12x8/4) to make all the screens similar at the facility. The following modifications would be required for the replacement:

- **Structural Modifications:** A notch will need to be created in the channel concrete wall that the ROMAG screen will rest on, to match the existing ROMAG screen design.
- **Control Panel Upgrades:** The new ROMAG screens have new standard sequence of operations, updated electrical devices and controls. The controls for the existing ROMAG screens should be upgraded with these new items, as follows:
 - A touch screen operator interface to provide better functionality to adjust various setpoints.
 - New control functions including short stroke, blocked carriage, pressure settings in each direction, repeat cycle timer, park at home positioning, and level on and off settings.
 - The solenoid valve used on the carriage on the existing ROMAG screens should be replaced with an electrically actuated valve which changes the valve position according to the pressure setting that is seen by the cylinder. The new ROMAG screens will come with the electrically actuated valve used on the carriage.
 - The sequence of operation should be changed to eliminate the intermittent operation of the rake, which would maximize the cleaning frequency regardless of the liquid level once the screen is activated.
 - An ambient temperature thermostat should be installed and when the ambient temperature reaches less than 35°F, the control sequence to cycle the oil weekly would be disabled during periods of freezing temperatures. This will avoid a fault condition when the materials stuck to the screens freeze during winter months.

The alternative evaluation is presented in Table 10-2. The sources of costs used in this evaluation are listed below:

- Capital costs for Alternative 1 were obtained from the screen replacement costs of the SRP.
- Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.
- Although there are O&M benefits to having all the same screens (i.e., similar spare parts and needed familiarity with only one screen type), the difference in O&M costs for the COPA and ROMAG is difficult to monetize. As such, O&M costs are not included in this analysis. This issue, however, is reflected in the Ease of O&M scores.

This evaluation shows that Alternative 1 is the Best Value Alternative. Because of the large difference in capital costs between the two alternatives, **Alternative 1 - Replace Existing COPA Screens In-Kind is the recommended alternative.**

Table 10-2. Alternative Evaluation for Screen Replacement (Project LEIB-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace COPA Screens In Kind	Health and Safety	3	2.78	\$ 3,524,000	\$ -	\$ 3,524,000	\$ 1,266,108	Best Value Alternative
	<i>Definition:</i>	Replace In Kind	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Need to maintain two different types of screens.	Component Performance	3						
	<i>Comments:</i>	Note: This is only replacing the COPA screens with COPA screens. The existing ROMAG screens are not included.	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Existing COPA Screens with ROMAG Screens	Health and Safety	3	3.55	\$ 6,224,000	\$ -	\$ 6,224,000	\$ 1,753,239	
	<i>Definition:</i>	Replace Existing COPA Screens with ROMAG Screens	Water Quality & Compliance	3						
	<i>Adv.:</i>	ROMAG screens offer a hydraulic benefit of allowing peak flows to overflow the top of the screen. Also, all screens would be identical, making maintenance and spare parts more efficient	Capacity Enhancement	4						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	Note: This is only replacing the COPA screens. The existing ROMAG screens are not included.	O&M Ease	5						

10.2.2 Disinfection

10.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, six low-rate diaphragm pumps, two high-rate centrifugal pumps, four disinfectant rapid mix zones, and 18 induction mixers. There are two channels with four ROMAG screens and two channels with Copa screens discharging into a screened effluent channel. From there screened effluent flows to four disinfectant rapid mix zones. There are four induction mixers per disinfectant rapid mix zone consisting of one pair of mixers upstream and one pair of mixers downstream of a concrete baffle wall that directs all flow down and past the mixers. There are also two induction mixers in the influent channel upstream of screening referred to as prechlorination mixers. Four of the low-rate sodium hypochlorite pumps are each paired to a disinfectant rapid mix zone. Flow is metered from each pump and then flow is split in a manifold to the four induction mixers in each disinfectant rapid mix zone. The manifold includes a solenoid valve, manual valve, and a sight flow indicator to each induction mixer. Flow splitting between induction mixers is primarily dependent on equal back pressure valve settings to the induction mixers. The other two low-rate sodium hypochlorite pumps are each paired to one of the influent channel mixers. The two high-rate pumps discharge to a four-way manifold with flow metering on each branch. These tie into the discharge from the four low-rate pumps upstream of the manifold to each disinfectant rapid mix zone. There are also valved connections allowing the high-rate pumps to be used for the influent channel induction mixers.

The design which was intended to provide redundancy and flexibility is atypically complex and results in the manifolds including valves and sight flow indicators to be inaccessible due to their height on the wall. Table 10-3 provides an overview of the existing disinfection system at Leib CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G

Table 10-3. Overview of Existing Disinfection System at Leib CSO Facility

Parameter	Value
Treatment Capacity (cfs)	1,550
Design Feed Strength (% hypochlorite)	7.5
Max. Dosage at Design Flow (mg/L Cl ₂)	38
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	10,450
Type	FRP
Pumps	
Number	8 Total; 6 low-rate, 2 high-rate
Capacity (gpm)	Low-rate: 7.6, High-rate: 112
Type	Low-rate: Diaphragm, High-rate: Centrifugal
Mixers	
Number / Type	18 / Chemical induction mixers
Model Number / hp / Manufacturer	SWC15FX / 15 hp / Water Champ

10.2.2.2 Identified Needs and Issues

The needs and issues identified for Leib were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are listed in the following bullets :

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Leib chemical feed system has the following issues:
 - Pumps are expensive to maintain and replace
 - Complex piping with a high number of components
 - Inaccessible manifold components due to height on wall
 - The VFDs and electrical equipment are located in the corrosive environment of the chemical room
 - The chemical feed pump and motor are difficult to remove from the containment area
 - Currently, a hose must be moved and connected to each pump suction pipe to flush the hypochlorite solution from the feed system with NPW. A hard-piped flushing water connection is desired so that flushing could be accomplished by opening a valve to each pump.
 - The chemical room floor has been damaged due to a chemical leak from one of the storage tanks.

These issues are addressed in Replace Chemical Feed System (Project LEIB-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project LEIB-DIS-2) below.
- There are 18 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project LEIB-DIS-3).

10.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project LEIB-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, LEIB-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to the Leib feed system:

- For cost estimating purposes, water piping and valving to each feed pump was assumed to allow water flushing for the entire chemical feed system from the feed pumps to the mixers.
- Move VFDs and electrical equipment out of the chemical room.
- For cost estimating purposes, a mast type jib crane (similar to the one described for Conner Creek) is assumed for moving the pumps and motors up and down the flight of stairs. The actual configuration should be included in the detailed design of a modified chemical feed system.

The alternative evaluation for these alternatives is presented in Table 10-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on manufacturer pump rebuilds at a cost of \$20,000 per year and GLWA onsite rebuilds at a cost of \$24,000 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 10-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 10-4. Alternative Evaluation for Replace Chemical Feed System (Project LEIB-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 1,262,400	\$ 44,000	\$ 2,190,344	\$ 1,051,365	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 1,724,000	\$ 26,750	\$ 2,288,148	\$ 635,597	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 901,000	\$ 3,000	\$ 964,269	\$ 267,852	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project LEIB-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Operation in manual at Leib is noted by operations as being extremely difficult. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time and the future additional flow from Meldrum diversion must also be considered. The exact location would be determined during design. The original design included a sample pump about 50 ft from the mixing chamber. The appropriateness of this location should be evaluated during design. However, the operability of this pump is not known because it is not currently used for sampling. Given the uncertainties regarding whether this sample point and the condition of the sample pump, the cost for a new manhole to access a sampling pump in the effluent conduit was included. A buried pipe was assumed in the cost estimate to convey the sample flow into the existing building where the TRC analyzer would be located.

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 10-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 10-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project LEIB-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	O&M to maintain analyzers based on 4 hrs/month.	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixer (Project CON-LEIB-3). Plant personnel report that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. The Leib facility has 16 chemical induction mixers in the mixing channels (and 2 pre-chlorination mixers, which would remain). A reduction in the number of mixers would reduce maintenance and the associated expense proportionate to the reduction. It would also reduce the complexity for equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4); however, due to facility constraints, vertical shaft mixers would not be feasible at this location, so that option is not included. The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** Computation fluid dynamic (CFD) modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from four to two per channel). This needs to be confirmed by collection system modeling performed by others. Capital and O&M costs per mixer are identical to Alternative 1.

The alternative evaluation is presented in Table 10-6. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$15,500 per mixer.

This evaluation shows that Alternative 2 – Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers is the Best Value Alternative. As such, **Alternative 2 – Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers is the recommended alternative.**

It should be noted that the cost of the reduced number of mixers is not a new capital improvement cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection performance can be achieved, the number of mixers would remain the same as the current number.

Table 10-6. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project LEIB-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace Existing Mixers in-kind	Health and Safety	3	2.57	\$ 1,600,000	\$ 84,800	\$ 3,388,401	\$ 1,320,156	
	<i>Definition:</i>	Replace existing mixers as required.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, lots of redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Expensive and impacts operations and maintenance. Equipment installed in basins.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	Health and Safety	3	3.00	\$ 850,000	\$ 42,400	\$ 1,744,200	\$ 581,400	Best Value Alternative
	<i>Definition:</i>	Perform computational fluid dynamics (CFD) model of basin and determine required number	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, maintains required redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less expensive and less impacts to operations and maintenance. Equipment installed in	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.3 Odor Control

There is no odor control system at the Leib facility. Building space for a carbon adsorber system, space in the electrical room for the fan motor, and a duct penetration to the screening facility below grade were provided, if odor control is needed in the future. However, odor complaints have not been received for this facility since it has been in operation. Therefore, an odor control system is not needed and, therefore, there are no associated "needs."

10.2.4 Flushing and Dewatering

10.2.4.1 Description of Existing System

The Leib CSO Facility does not have a dedicated dewatering or flushing system for the screening and disinfection area. The facility drains by gravity and, due to the limited use, solids accumulation has not been a major issue at this facility, with the exception of the screening channels, which are discussed in the next section.

The outfall conduit has dewatering pumps to dewater the lower portion of the effluent conduit. These pumps are located near the Outfall Sample Building. The dewatered flow is pumped to the DRI.

Table 10-7 provides an overview of the existing flushing and dewatering system at Leib CSO facility.

Table 10-7. Overview of Existing Flushing and Dewatering System at Leib CSO Facility

Parameter	Value
Headworks Dewatering and Flushing System	Headworks (basin) area is dewatered by gravity to the Toward Treatment sewer or disinfection conduit.
Effluent Conduit Dimensions	16-ft-dia. effluent sewer to Junction Chamber, two 11-ft-dia. pipes to dewatering gate, two 10 ft × 10.5 ft box conduits to Detroit River
Effluent Conduit Dewatering and Flushing System	- Two 1,500 gpm dewatering pumps located near Effluent Sample Building are used to dewater lower end of effluent conduit. Flow is pumped to the DRI - There is no flushing system in the effluent conduit.

10.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Flushing the screening channels after every storm event is difficult and time-consuming.
- The existing four screening channels cannot be isolated from the influent flow during rehabilitation or extensive maintenance activities. Jacobs reviewed options to install stop logs or sluice gates at the influent end of each channel. Although there is space for new slots to be constructed for either a new gate or stops logs, the lack of isolation of each screen channel from another channel downstream of the proposed gate would not provide the desired isolation. As such, there does not appear to be a feasible way to isolate channels. The current practice of installing scaffolding in the screen channels appears to be the best alternative.

10.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screening Chamber Flushing (Project LEIB-FD-1). The screening channels must be manually sprayed down after every event. Flushing from the surface is somewhat difficult and time-consuming. There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing.** Continue manual flushing.
- 2) **Alternative 2: Screening Chamber Flushing System.** A new flushing system piped from the existing NPW line, extending down to the screen channel floors and drilled with holes through the HDPE pipe is recommended to address this issue. Figure LEIB-FD-1-ALT-2, included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

The alternative evaluation for these alternatives is presented in Table 10-8. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 includes GLWA labor cost. It is based on 2 hours per event and 25 events per year, at \$100 per hour rate.
- It is assumed that the cost of water is similar between the two alternatives, so it is not included in this evaluation.

This evaluation shows that Alternative 2 – Screening Chamber Flushing System, is the Best Value Alternative. **As such, Alternative 2- Screening Chamber Flushing System is the recommended alternative.**

Table 10-8. Alternative Evaluation for Screening Chamber Flushing (Project LEIB-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.57	\$ -	\$ 5,000	\$ 90,228	\$ 35,154	
	<i>Definition:</i>	Do Nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Flushing from the surface is somewhat difficult and time-consuming	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Screening Chamber Flushing System	Health and Safety	3	3.43	\$ 16,000	\$ -	\$ 16,000	\$ 4,660	Best Value Alternative
	<i>Definition:</i>	A new flushing system piped from the existing NPW line, extending down to the screen channel floors and drilled with holes through the HDPE pipe	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less time to clean channel	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

10.2.5 HVAC

10.2.5.1 Description of Existing System

The Leib CSO facility consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground influent channel. Table 10-9 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, and emergency eyewash shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 10.2.10.

Table 10-9. Major HVAC Equipment at Leib CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks (Screening Chamber)	SF-1	Supply Fan	59,000 CFM
Chemical Room	HV-2	AHU	2,700 CFM 300 MBH
	EF-2	Exhaust Fan	3,010 CFM
Electrical Room	HV-1	AHU	2,700 CFM 300 MBH
	EF-3	Exhaust Fan	4,650 CFM

Table 10-10 provides a summary of the basis of design performance criteria for HVAC systems at Leib and Table 10-11 provides the outdoor Basis of Design conditions.

Table 10-10. Leib Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Headworks	Class I, Group D, Div 1	N/A	N/A	12 ACH (Occupied)
Mechanical Spaces	Unclassified	60	96	Heat Relief
Office, Sampling Room, and Toilet Rooms	Unclassified	70	78 F Dry Bulb, 50% Relative Humidity	15 cfm per occupant

Table 10-11. Leib Original Outdoor Basis of Design Conditions

Outdoor Design Temperature		
Winter (Dry Bulb °F)	Summer (Dry Bulb °F)	Summer (Wet Bulb °F)
3	91	73

10.2.5.2 Identified Needs and Issues

During the CS-299 Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- Odor issue in Basin and Garage area. The louvered penthouses next to the stairwells had been seized closed and the supply air to the Headworks Area was not able to be relieved through the penthouses. This may have caused odorous air to be pushed out of the large blind flange for a potential future odor control system. It was noted after the meeting that the on-going CIP project HVAC Improvements, CIP 260611, GLWA Contract No. 1803718 will be restoring the louvers in the penthouses and installing new gasketing for the blind flange in the garage area. This should reduce odors in the garage.
- Access to SF-1 for maintenance and repair is difficult: There is very little clearance to service belts and bearings in the supply fan room.
- The Headworks is not provided with any heat: O&M staff noted that water has to be turned off after about November to prevent pipes from freezing and that humidity in the air can cause major condensation in the Headworks.
- Jacobs further evaluated this issue. The Headworks area was not originally designed to be a conditioned space. Adding heating/dehumidifying to prevent frozen pipes and condensation would be prohibitively expensive. Insulating and heat tracing pipes to prevent freezing was considered; however, heat tracing can fail without warning and then pipes could still freeze. Keeping a small flow of water through the pipes during the extreme winter cold periods could be explored. No capital costs have been applied to this issue.
- Improved cooling is needed in the control room. Jacobs further investigated this issue. GLWA's HVAC contractor noted that there have been major control issues at the facility in the past and control installations are taking place presently which should help improve operator comfort. It is recommended that the impact of the control changes on operator comfort be assessed after they are completed, and recommendations can be made for proposed changes if conditions do not improve. It should also be noted that the cooling equipment serving the office, sampling room, and toilet rooms was sized to provide a summer indoor temperature of 78°F. Because an operator routinely occupies the control room, consideration should be given to sizing the next AC unit for 72°F. No capital costs have been applied to this issue. The AC unit will be replaced.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- Dampers on HV-1 and HV-2 mixing boxes are not completely functional: GLWA's HVAC contractor noted although the actuators on the dampers are being replaced as part of an on-going project, the dampers may be in poor shape. Currently, they manually actuate the dampers.

During site investigations (June 2020) the following observations were noted:

- A roof has been constructed over both Entrance Courtyards: The as-built drawings show that these areas had no roof when they were originally constructed. Roofs have since been constructed over these areas with screens to keep out birds and insects. See discussion and photos below for further details.
- The on-going HVAC-related upgrade project (CIP No. 260611) will be upgrade the HVAC control system with DDC, replace dampers and actuators in the penthouse and within the indoor HVAC system, and replace the actuator and damper for the supply air to the basement.

10.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project LEIB-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: HVAC Improvements** including,
 - Entrance courtyard modifications
 - Improved access to SF-1 for maintenance

Each of the HVAC related improvements listed above is described further below:

Entrance courtyard modifications. Another potential source of odors and a code compliance issue are the stairwells which are currently connected to the interior unclassified areas of the facility via the Entrance Courtyards on the East and West sides of the facility (Figure 10-2). The as-built drawings (Figure 10-3) show these areas as having no roof. This design does not constitute an enclosed space under NFPA 820 because it is open to the atmosphere. The building has been modified since construction to include a roof over both Entrance Courtyards and has been enclosed with bird screen between the existing wall and newly constructed roof.

Figure 10-2. Existing West (left) and East (right) Entrance Courtyard

Figure 10-3. As-Built Entrance Courtyard Design – Section through Building

NFPA 820 defines a space with a roof as “Not Enclosed” if 50 percent of its wall area is open to the atmosphere. This is clearly no longer the case with either of the Entrance Courtyards (Figure 10-4).

Due to their connection to the Headworks Area, the stairwells are technically Class I, Division 1 spaces per NFPA 820. The fact that they are connected to other areas of the facility via man doors, through the now enclosed Entrance Courtyards, effectively classifies the rest of the facility as Class I, Division 1. Although the Entrance Courtyards have combustible gas detection and some relief to the atmosphere, current versions of NPA 820 make it clear that such connections between unclassified and classified areas are only allowed via a pressurized airlock, with combustible gas detection monitoring and alarm, positive pressurization monitoring and alarm, and alarm if the airlock door is open for more than 20 seconds. This is not a feasible solution for the West Entrance Courtyard due to the intake for the Emergency Generator room in this area, but may be feasible for the East Entrance.

Figure 10-4. Entrance Courtyards – Plan view

To comply with NFPA 820 and ensure that hazardous gasses cannot enter the facility through the Entrance Courtyards in the future, Entrance Courtyard roofs should be removed.

Improved access to SF-1 for maintenance. SF-1 supplies ventilation air to the Headworks area and therefore the supply fan room is also a Class I, Division 1 area. Creating openings in either the generator room or garage area to improve access were considered; however, these would violate the physical separation between the classified supply fan room and unclassified generator room and garage area. One option would be to demolish the east wall of the supply fan room and move it further east with man door access added in the north wall, if necessary. See Figure 10-5 below.

Figure 10-5. Supply Fan Room – Plan view

The alternative evaluation is presented in Table 10-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- Although the access to maintain SF-1 would be improved by moving the wall, it is difficult to monetize this benefit. As such, there is no measurable difference in O&M costs between the two alternatives.

Alternative 2 is recommended based on the need for code compliance. This project should be conducted when a major upgrade is performed at the facility.

Table 10-12. Alternative Evaluation for HVAC Improvements (Project LEIB-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Does not meet current code and very difficult access to SF-1 for maintenance	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	4	3.72	\$ 126,000	\$ -	\$ 126,000	\$ 33,901	Not Applicable
	<i>Definition:</i>	Improved access to SF-1 and address code issues.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved access for maintenance and improved safety.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

10.2.6 Electrical

10.2.6.1 Description of Existing System

The Leib facility's electrical system consists of one DTE utility feed from a 480 V, 3-phase outdoor transformer (secondary metering) and one diesel generator feed from a 350 kW, 480 V, 3-phase stationary generator. The utility feed is connected to a 600 A motor control center (MCC-B) with a 600 A sub-feed connection to a 600 A ATS. The ATS then feeds a distribution panel with two 600 A breakers, which feeds two MCCs (MCC-A and MCC-C). The MCCs feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 10-13 provides a summary of the major electrical equipment for this facility.

Table 10-13. Major Electrical Equipment at Leib

Location	Major Electrical Equipment	Description
Generator Room	Generator (Diesel)	350 kW, 480/277 V, 3-Phase
Electrical Room	MCC-A	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-B	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-C	600 A, 480/277 V, 3-Phase

10.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The operators need to call an electrician to reset the mixer units, which is time consuming.

10.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project LEIB-ELEC-1). The operators need to call an electrician to reset the mixer units, which is time consuming. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Continue calling the electrician to reset the mixer units.
- 2) **Alternative 2: Electrical Improvements.** Add Reset Buttons to the outside of the MCC buckets for each chemical induction mixer motor. See Figure LEIB-ELEC-1-ALT-2 in Volume 6 – Appendices, Appendix C for location. The reset buttons will enable Operations to reset the mixers themselves when a trip occurs instead of contacting electricians to reset the mixer unit.

The alternative evaluation is presented in Table 10-14. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is only \$6,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 10-14. Alternative Evaluation for Electrical Improvements (Project LEIB-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	The operators need to call electricians to reset the mixer units, which usually takes a long time.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	3	3.43	\$ 19,000	\$ -	\$ 19,000	\$ 5,534	Not Applicable
	<i>Definition:</i>	Add reset buttons to the outside of the MCC buckets for each chemical induction mixer motor	Water Quality & Compliance	3						
	<i>Adv.:</i>	The operators do not need to call electricians to reset the mixer units	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

10.2.7 I&C

10.2.7.1 Description of Existing System

Control System: The original control system was installed in 2002 under PC-732. In 2004 the system was upgraded and interfaced into GLWA's overall SCADA Ovation control system. This upgrade provided the ability to remotely monitor the operations of the facility and the local collection system at SCC.

The existing control system contains an Allen Bradley-based PLC system consisting of an Allen-Bradley redundant PLC-5 with local I/O controls that are installed in the facility's local control system panel. The operator workstation software has a Rockwell RSVIEW operating platform and is located in the control room. The existing hardwired local back-up control panel and other miscellaneous subsystems that are incorporated into the overall control system are outdated and need replacement. The control system network and switches are obsolete and do not meet GLWA SCADA Governance standards on redundant networks and switches, and that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a back-up radio system to communicate critical monitoring points back to GLWA System Control on wide area network failure.

Flow and Level Sensors: Table 10-15 summarizes the level sensors and flow meters at the Leib CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 10-15. Summary of Flow Meters and Level Sensors at Leib CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent Sewer (Larger Sewer)	1	Transit-Time (AccuSonic)
Influent Sewer (Smaller Sewer)	1	Transit-Time (AccuSonic)
Towards Treatment Sewer	1	Transit-Time (AccuSonic)
Outfall	1	Transit-Time (AccuSonic)
CSO Facility Level Sensors		
Influent (Sewer and channel)	2	Ultrasonic
Mixing Chamber	1	Ultrasonic
Dewatering (Pumping station and control gate)	2	Ultrasonic
Effluent (Outfall, Towards Treatment Sewer)	2	Ultrasonic
DRI Discharge Regulator Chamber	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed Pumps	8	Magnetic

10.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Install an Outfall OIT

- Evaluate repair or replacement of the DRI level sensor
- Need for remote control of the regulator gates
- Ensure influent flow meter is properly positioned with new Meldrum connection
- Need for process cameras at select locations
- Evaluate influent flow meter will be properly positioned with new Meldrum connection. Based on GLWA's WWMP, a new diversion sewer is proposed to connect the Meldrum Sewer to the Conant-Mt. Elliot Sewer, which will divert flow from Meldrum to the Leib CSO Facility during wet weather events. GLWA staff expressed concern that the proposed location of the new junction chamber may impact the accuracy of the existing multi-path flow meter. The approximate location of the existing flow meter, as well as the proposed location of the new diversion sewer was shown previously in Figure 10-1.

The existing meter will likely be in a zone of higher turbulence near the new sewer connection, which will result in less accurate flow measurement. It is recommended that the flow meter be about 10 pipe diameters, or 160 ft, from the proposed junction chamber to ensure that the meter functions reliably. The proposed junction chamber is approximately 240 ft upstream of the existing influent diversion chamber to the CSO facility. As such, there is sufficient pipe length to relocate the meter downstream. In discussions with GLWA, Jacobs recognizes that the flow meter will be replaced in the near future. It would be most efficient to relocate the meter to a point that would account for the future diversion flow. Because a new influent flow meter is going to be installed at this location, costs are not provided in this report for relocation to address this issue.

- Need to replace the regulator gate limit switches. Replacement of the switches will likely require dewatering and flow diversion in the regulator structure, which could be a significant effort and cost. As such, this work should be considered for combination with other upcoming work at or near this location.
- The control system should be upgraded. GLWA is currently developing an FP) for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities." The project will replace the existing PLC-5 control system and back-up local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an on-going project that has already been included in the CIP.
- The screen graphics are very difficult to understand and should be updated to match other facilities. This improvement is included in the Control System Improvements project described in the previous bullet.
- Evaluate regulator gate limit switches. Remote control of the regulator gates is included under the "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project. No further improvements are recommended.

10.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project LEIB-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation Control System Upgrade and the Automatic Transfer Switch and Generator Controls Upgrade, are

proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: I&C Improvements** including,

- Install an Outfall Operator Interface Terminal (OIT)
- Evaluate DRI level sensor
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Install an Outfall Operator Interface Terminal (OIT). In order to assist operations during CSO events, Operators requested an OIT at the Outfall. The OIT should be consistent with other OIT panels being installed throughout other CSO Facilities under the I&C Systems Project.

Evaluate DRI level sensor. It is recommended to replace the DRI level sensor.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 10-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – I&C Improvements has a total benefit score about 0.9 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and O&M. The NPV/Benefit cost for Alternative 2 is \$49,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 10-16. Alternative Evaluation for I&C Improvements (Project LEIB-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.53	\$ 109,000	\$ 3,000	\$ 172,269	\$ 48,755	Not Applicable
	<i>Definition:</i>	Install higher performance I&C instruments including Outfall OIT, level sensor, regulator gate limit switches, and process cameras. Project may be able to be split into multiple delivery projects if needed.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	5						

Control System Upgrade. The following control system improvements are recommended:

- Update Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

GLWA is currently developing an RFP for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Leib CSO Facility under *"Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities"*. The project will replace the existing PLC-5 control system and back-up local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace most of the field instruments.

The alternative evaluation table is not provided because this is an on-going project that has already been included in the CIP.

10.2.8 Site

10.2.8.1 Description of Existing Site

The Leib CSO facility was built in 2002. The site includes a 6-ft high security fence along the perimeter of the site. A sliding cantilever entrance gate is provided at the Mt. Elliott entrance. The parking lot consists of 8-in thick reinforced pavement with 8-in. crushed limestone base. There is a 5-ft wide, 4-in. thick sidewalk along the building entrances and 10-in. aggregate site pavement along the perimeter of the facility. Site utilities include potable water, natural gas, electrical, telephone services, stormwater, and sanitary sewer connections.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

10.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- There are safety concerns for those accessing the Leib CSO facility through the sliding cantilever entrance gate off of Mt. Elliot St.
- Need for additional space to store outside summer/winter site maintenance equipment. Jacobs evaluated this issue. All the equipment required for outside summer/winter site maintenance is stored inside the Leib facility in the space originally planned for the odor control room outside the control room. GLWA has requested additional space to store this extraneous equipment outside of the building. There is limited space for a permanent structure on the site without locating it over the treatment basin or influent/effluent conduits. One available location is at the south side of the property where there is an approximately 15-ft wide strip inside the fence line. The available area will depend on the required size of the storage building. While there is limited space on the current facility site to construct a permanent storage structure, it may be possible to locate a new storage building if

property is acquired for the new access drive entrance and the security fence and new gate alignment can be realigned to accommodate a secure area for a new storage building.

- Based on our understanding of the equipment to be stored, it appears that a small commercial secure garden shed style structure would be adequate; however, a more secure option would be to continue to utilize the existing space inside the Leib facility and plan for a storage facility outside as a new larger space may become available. As such, no capital costs have been provided for this issue.
- The Leib facility influent and effluent diversion junction chambers are located in Mt Elliott St. outside the facility boundary extending across two lanes of north bound traffic (approximately 20 ft in width). The diversion chambers were constructed on piles. The concrete junction chambers extend to the surface in Mt. Elliott St. Settlement of the asphalt-surfaced road has occurred around these structures. The settlement issue is more pronounced at the effluent diversion structure. We recommend that the roadway around the structures be reconstructed with a modified engineered fill that can help stabilize the roadway surface around the structures. As Mt. Elliott is a city-owned road, road reconstruction should be performed by the City of Detroit. However, a line item is included in the New Access from Meldrum Street project to address this issue.

GLWA is currently addressing some of the site needs at the facility. These on-going projects are described below and are not included in the capital improvement projects for CS-299:

- There are significant water infiltration issues at the Leib Outfall Sampling Vault near the Detroit River. The Sampling Vault shares a common wall with the east barrel of the outfall. A number of conduits carrying power and control wiring and cables penetrate the common wall near the base of the vault that corresponds with the elevation of the base of the outfall. The existing conduits service dewatering and sampling pumps, level sensors, proximity switches on backwater gates and a multi-path transit time flowmeter located upstream of the Sampling Vault. When wet weather events occur, infiltration into the conduits flows back into the Sampling Vault, flooding the base of a floor mounted control panel.

To prevent the backflow of treated water into the Sampling Vault, it is recommended to realign the penetrations of the existing conduits to an elevation above the waterline in the outfall conduits. The existing conduit penetration should be demolished, removed and the openings grouted shut. There are six 1.25- in. conduit penetrations and two 2-in. conduit penetrations that would have to be relocated. This is an on-going project and will be completed through a JOC.

- The following issues were addressed under GLWA-CON-1902040 "Site Improvements at P-F Detention Facility and Leib Screening and Disinfection Facility" Contract.
 - Address Facility Drainage. The surface of grade over the treatment facility is very flat and as a result water ponded on it.
 - Repair Concrete Sidewalk. The 4-ft wide access sidewalk around the perimeter of the Leib CSO facility has been impacted by settlement issues that have caused the sidewalk to pull away from the building and crack.
 - Caulk joints at expansion joint between base of wall/sidewall – all sides of building.
 - Seal all control joints and cracks in the concrete parking lot pavement.
 - Repair collapsing catch basin.

10.2.8.3 Description and Evaluation of Alternatives

A project to address the need identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

New Site Access from Meldrum Street (Project LEIB-SITE-1). The existing site access through the sliding cantilever entrance gate off of Mt. Elliott St. creates safety concerns for those accessing the Leib CSO facility site. The existing site fence line and security gate on the west side of the facility is located immediately behind the street sidewalk. As a consequence, there is not enough space for vehicles to completely pull forward onto the drive approach to the site without the vehicle remaining partially in the lane of traffic on Mt. Elliott. As a result, some drivers exit their vehicles while in traffic to swipe security access cards to open the gate. Furthermore, some drivers park their vehicle in the turn lane and cross the traffic to open the gate. This poses a slip and fall safety concern, especially in the winter in inclement weather. Several alternatives have been investigated to address this issue, including realigning the fence and gate location off Mt. Elliott so that vehicles can pull fully out of the traffic lane to access the card reader and wait for the gate to open. This alternative, however, does not appear to be practical due to the significant encroachment on the existing parking lot necessary to create space for cars and trucks to pull off Mt. Elliott Street. In addition, realigning the gate would not allow proper maneuverability for vehicles in the parking lot.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: New Site Access from Meldrum Street.** This alternative includes relocating the site entrance to the east side of the site off Meldrum Street. See Figure LEIB-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the conceptual layout. There are several parcels of vacant property immediately adjacent to the east side of the Leib facility. Three of these parcels align with the existing Leib parking lot on the north side of the facility. An access road could be constructed off Meldrum to allow an alternative entrance to the Leib facility. This alternative would include construction of a new 24-ft wide access driveway. The length of the drive would be approximately 175-ft off Meldrum. The facility's existing east fence line would be modified to accommodate a new sliding cantilever gate and access card reader. The Detroit GIS parcel database indicates the vacant properties on the east side of the site are owned by the Detroit Water and Sewerage Department.

This alternative includes the paving of Mt. Elliot in front of the Leib facility.

The alternative evaluation is presented in Table 10-17. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.15 higher than the Do Nothing Alternative (Alternative 1) based on the improved safety and component performance. The NPV/Benefit cost for Alternative 2 is \$65,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 - New Site Access from Meldrum Street, is the recommended alternative.**

Table 10-17. Alternative Evaluation for Site Access (Project LEIB-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	3						

10.2.9 Architectural

10.2.9.1 Description of Existing Facilities

The Leib CSO facility consists of chemical room, utility support (electrical, emergency generator and mechanical), control room, odor control room, screen room, sampler room and other miscellaneous rooms. The facility also includes an underground influent channel.

10.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated the leak from the chemical storage tank damaged the floor coating in the chemical room. The recoating of the floor is included in LEIB-DIS-1 project.

10.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (LEIB-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) Alternative 1: Do Nothing.

2) Alternative 2: Architectural Rehabilitation. Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints
- Remove and replace isolation/ cove joint sealant and around building perimeter
- Clean and coat bottom of all door frames
- Clean corrosion and coat underside of roof deck

- Clean and coat localized areas of roof beams and framing members
- Remove debonding roof deck paint, clean and replace with new paint
- Replace cracked limestone windowsill and caulk on the southeast side of the building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure LEIB-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (LEIB-DIS-1).

The alternative evaluation is presented in Table 10-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 10-18. Alternative Evaluation for Architectural Rehabilitation (Project LEIB-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 246,000	\$ -	\$ 246,000	\$ 79,355	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.10 Safety

10.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

10.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 10-19. The capital improvement project to address these issues is included in the table.

During the Needs Assessment meeting for Disinfection, O&M staff noted the tanks lack fall protection to allow safe access to appurtenances and valves above the tank. Fall protection is desired for safety.

It is recommended that either the handrail style fall protection, similar to Belle Isle and Oakwood, or the solid style fall protection similar to Hubbell-Southfield be added to the top of the two hypochlorite tanks. This will require a technician skilled in working with FRP to bond the fall protection to the tank. FRP tank manufacturers offering field repair services would be able to do this work.

Table 10-19. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Garage	No exit sign	Add exit sign	Exit Sign Improvements ^a
Chemical Room	No guardrails on tanks	Add guardrails	Safety Improvements (Project LEIB-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project LEIB-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

10.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project LEIB-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend guardrails on tanks in the chemical room to eliminate fall hazard
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 10-20 shows the one alternative.

Table 10-20. Alternative Evaluation for Safety Improvements (Project LEIB-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 211,000	\$ -	\$ 211,000	\$ 70,333	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Leib CSO Facility.

10.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Leib CSO facility, Table 10-21 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 10-21, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 10-21. Listing of Asset Condition Assessments for Leib Facility

Asset Type	Total No. of Assets in Asset Type	# of Visual Condition Assessments	# of Detailed Condition Assessments	% of Assets with Condition Assessment

UPS	3	3	0	100%
VALVE	4	4	0	100%
WATERHTR	1	1	0	100%
^a The fire suppression was evaluated Simplex Grinnell in 2018 and not included in the ACES report. ^b The gas detector is a portable unit and was not assessed. ^c The one pump not evaluated was a sample pump originally in the in the disinfection channel, which is no longer used.				

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Leib Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

10.3 Capital Planning for Leib CSO Facility

10.3.1 Summary of Capital Improvement Plan Projects

Table 10-22 provides a summary of the recommended CIP projects and associated capital costs for the Leib CSO facility based on the alternative evaluations conducted for this facility .

Table 10-22. Summary of Recommended Projects at Leib CSO Facility

Project No.	Alternative	Description	Total Project Cost
LEIB-DIS-1	3	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 901,000
LEIB-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
LEIB-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
LEIB-FD-1	2	Screening Chamber Flushing System	\$ 16,000
LEIB-HVAC-1	2	HVAC Improvements	\$ 126,000
LEIB-ELEC-1	2	Electrical Improvements	\$ 19,000
LEIB-I&C-1	2	I&C Improvements	\$ 109,000
LEIB-I&C-2	1	Control System Upgrade	Ongoing Project
LEIB-SITE-1	2	New Site Access from Meldrum Street	\$ 220,000
LEIB-ARCH-1	2	Architectural Rehabilitation	\$ 246,000
LEIB-SAFE-1	1	Safety Improvements	\$ 211,000

10.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 10-23. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 10-23. Capital Improvement Plan Projects for Leib CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
LEIB-1 Disinfection System Improvements	\$ 1,206,000	2026 <i>Timing based on implementation of projects before Meldrum diversion to ensure reliable operation with increased flows.</i>	LEIB-DIS-1	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 901,000
			LEIB-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
			LEIB-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
			LEIB-FD-1	Screening Chamber Flushing System	\$ 16,000
			LEIB-ELEC-1	Electrical Improvements	\$ 19,000
LEIB-2 Facility-Wide Safety and Architectural Improvements	\$ 583,000	2023 <i>Project should be initiated as soon as possible</i>	LEIB-HVAC-1	HVAC Improvements	\$ 126,000
			LEIB-ARCH-1	Architectural Rehabilitation	\$ 246,000
			LEIB-SAFE-1	Safety Improvements	\$ 211,000
LEIB-3 I&C Improvements	\$ 109,000	2030 <i>Timing based on best judgement</i>	LEIB-I&C-1	I&C Improvements	\$ 109,000
LEIB-4 Site Improvements	\$ 220,000	2026 <i>Timing based on need to address safety issue</i>	LEIB-SITE-1	New Site Access from Meldrum Street	\$ 220,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 10-24 and Table 10-25 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 10-24 indicates that LEIB-DIS-1 project has 28 assets that has an average condition score of 1.29 and an average replacement date of 2032. However, this project should be completed before the Meldrum diversion and therefore, the project was proposed a scheduled construction completion date of 2026 instead of 2032.

Table 10-24. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
LEIB-DIS-1	28	1.36	1.29	2.27	13	2032	\$ 904,400

Table 10-25. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
LEIB-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

10.3.3 20-Year Capital Outlay Plan

Table 10-26 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 10-26. 20-Year Capital Outlay Plan for Leib CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 300,900	\$ -	\$ -	\$ 217,500	\$ 59,200	\$ -	\$ -	\$ 24,200	\$ -	\$ -	\$ -	\$ -	\$ -
2022	\$ 1,814,757	\$ -	\$ 1,814,757	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2023	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -

Notes:

Explanation of large capital outlays in first two years:

- Screening System: Screen #3, #5, and #7 received a score of 5 as the screens failed to start at the time of the Condition Assessment.
- Retention System: One Accusonic flow meter (FM-3; \$217,500) was not functional based on SCADA review in 2019 and 2020.
- Disinfection System: One chemical storage tank #2 (\$59,200 each) received a score of 5 as it had a small leak and had been taken out of service until repaired.

11. Oakwood CSO Control Facility

11.1 General Facility Description and Future Capacity Considerations

11.1.1 General Facility Description

The Oakwood CSO Facility is an RTB with 9 million gallons (MG) of storage and a treatment capacity of 1,660 cfs. It was constructed in 2012. There are three buildings. The main building contains the Storm Pump Station, Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, MAU room and hydraulic room. The basin odor control room contains the odor control systems for the East and West Basins.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

11.1.2 Northwest Interceptor Diversion to Oakwood CSO Facility

The WWMP proposed projects to increase wet weather flows to existing CSO facilities to maximize the use of the facilities and minimize the construction of additional facilities. Many of the CSO facilities do not reach their design flows, so there is capacity to accept additional flows, without exceeding their design flow.

The NWI Diversion to Oakwood CSO Facility is one of the recommended projects from the WWMP that will increase flows to the existing Oakwood CSO Facility. The magnitude of the increased flows and the potential impact on screening and disinfection performance is described in the following sections.

This project originated from the WWMP and involves diverting NWI flows to the Oakwood Storm Pump Station and CSO facility whenever the Detroit WRRF is overloaded, and capacity is available at the Oakwood facility. Based on information presented in the WWMP, the predicted peak wet weather flow rate expected at the Oakwood Pumping Station (PS) for the 10-year 24-hour storm event is about 1,100 cfs. The firm capacity of the Oakwood PS and the design flow for the CSO facility is 1,660 cfs. This leaves about 560 cfs of unused capacity at the Oakwood facility at design conditions.

The NWI diversion involves construction of a new control gate chamber on the NWI at Bayside and Sanders. About 3,100 ft of 10-ft-diameter tunnel is required to convey the peak wet weather flows from the NWI control gate chamber to a new diversion chamber at Liddesdale and Pleasant Streets, near the Oakwood influent junction chamber.

11.2 Facility Assessment

11.2.1 Screening

11.2.1.1 Description of Existing System

The Oakwood CSO Facility has six perforated plate screens that were installed in 2012. Raw wastewater is pumped to the screens from the Oakwood Storm Pump Station. Screened flow enters either one or both of the CSO basins via the Screen Outlet Chamber.

Screened material is removed from the screens using a rotating brush and high-pressure spray and discharged into a screw conveyor. The conveyor transports the screenings to a dumpster for eventual disposal in a landfill. A washer/compactor was originally installed at the end of the conveyor, prior to discharge to the dumpster.

The sanitary pump station has two manually cleaned bar screens upstream of the sanitary pumps. Space was provided in the Sanitary Pump Station for a monorail system and bucket that could be used to manually clean the screens if it were determined necessary in the future.

Table 11-1 provides an overview of the existing screening system at Oakwood CSO facility.

Table 11-1. Overview of Existing Screening System Oakwood CSO Facility

Parameter	Value	
Type	Retention Treatment Basin	Sanitary PS
Treatment Capacity (cfs)	1,660	NA
No. of Screens	6	2
Manufacturer	Andritz	Not known
Screen Type	Perforated Panel Screen	Manual Bar Rack
Opening Size	6-mm perforation	3-in.
Depth or Length	21 ft 6 in.	41 ft
Width	10 ft 0 in.	5 ft 0 in.
Screen Cleaning	Brush and high-pressure spray	Manual
Screening Removal	Screw conveyor to dumpster and landfilled	Manually cleaned (currently by washing screenings through the screens to the sanitary pumps)

11.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide a better means of cleaning the two bar racks at the sanitary pump station: The bar racks have 3-in. spacing to protect the sanitary pumps by capturing large debris. The sanitary pump station bar racks, however, become frequently blinded. During Jacobs Condition Assessment in June 2020, the differential through the screens was about 10 ft. The screens reportedly had not been cleaned for a prolonged period due to accessibility issues. The current method of cleaning involves lowering a worker in a man-basket into the wet well to manually remove the debris, which poses considerable safety risks. Alternatives to address this issue are discussed in the following section.
- Resolve water carry-over into screenings dumpster and onto floor near dumpster: Screenings and spray water from the screens are conveyed by the screw conveyor directly into the dumpster at ground floor. There is a significant amount of water that completely fills the dumpster during an event and spills onto the floor around the dumpster. A portable screenings washer/compactor was provided in the original system and can be moved into place to wash and compact the screenings. The washer/compactor has a drain that can divert the excess water to a drain line. The compactor, however, has been problematic because screenings fill the compactor chute, dry in place, and are unable to be pushed out of the chute during the subsequent storm. As such, the washer/compactor is bypassed.

- Jacobs recommends replacing the inclined discharge chute with a minimally modified chute. This will minimize compaction of the screenings and, most importantly, will allow the excess water to drain from the screenings prior to discharge into the dumpster below. This should significantly reduce the amount of water transferred to the dumpster. Jacobs contacted the washer/compactor manufacturer (JWC) to confirm this approach. The GLWA millwrights could construct and install a new horizontal section. The capital expenditure for this modification is minimal and not included in the capital outlay.
- Potential impact of higher flows on screening performance. The screens have not experienced peak design flows, and there is a concern that they may blind at the higher flows with the NWI diversion. It should be noted that the screens have emergency bypasses built-in to the screening channels to allow flows around the screens if the screens should become blinded. If screen blinding should become a problem in the future, potential modifications to the existing screens, including speeding up the screen, could be investigated. There is no room for additional screens at the facility.

11.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Sanitary Pump Station Screen Improvements (Project OKW-SCR-1). The existing manually raked bar screens excessively blind over time and cleaning them is a safety concern. There are four alternatives:

- 1) **Alternative 1: Do Nothing/Keep Existing Manual Bar Rack**
- 2) **Alternative 2: Remove Bar Racks.** The bar racks were installed to protect the sanitary pumps. Due to the excessive blinding of the bar racks, GLWA recently temporarily removed the bar racks. This will allow observation of pump performance without screening. If the pumps can convey most of the debris, this could be the long-term alternative. GLWA should observe this performance for at least a year to determine the impacts on the pumps and the material that remains in the wet well.
- 3) **Alternative 3: Monorail and Clamshell.** The facility was originally designed for a monorail and clamshell to remove the screenings from the manual bar racks, but it was not installed. A clamshell could be used to clean bar racks with 3-in. openings as the captured debris is usually large/heavy. A clamshell would be faster and safer to use than the man-basket that was previously used. However, GLWA subsequently requested a mechanical bar screen in lieu of continuing to use the manual bar racks based on operational experience with clamshells being unreliable.
- 4) **Alternative 4: Mechanical Bar Screen.** The bar racks could be replaced with mechanical bar screens with the same 3-in. bar spacing that extend the full depth of the channel. Duperon's FlexRake FP-F bar screen was evaluated and would perform well (see Figure OKW-SCR-1-ALT-4 in Volume 6 – Appendices, Appendix B). It was used as a representative screen for cost estimating purposes. A smaller bar spacing of 1.5-in. is an option but will result in additional screenings to manage. The spacing of a new screen, if this option is selected, should be further evaluated during detailed design.

Several options for screenings handling were evaluated for the mechanical screens in Alternative 4:

- **Screenings Handling Option 1: Rolling Dumpster:** A rolling dumpster with a drain should be adequate for screenings from a 3-in. bar screen. The portable dumpster could be moved just outside the roll-up door and picked up by a trash truck. Screenings captured with a 3-in. bar screen are not expected to be odorous.
- **Screenings Handling Option 2: Grinder After Mechanical Screen:** Rather than disposing of screenings at the Oakwood facility, screenings could be ground and returned to the screened wastewater and conveyed to the WRRF. Screens at the Detroit WWTP would remove the ground screenings. The grinder teeth can be set to grind the screenings to the desired size, so they are mostly removed by the treatment plant screens. Conversations with a Jacobs' screening expert

and Duperon indicated that maintenance on the grinder will be intensive due to the large material that will be ground. The likelihood and frequency of jammed grinders is high, and a rolling dumpster is a better disposal option.

- Based on the evaluation above, a rolling dumpster (Screenings Handling Option 1) is recommended as a grinder has a higher potential for future maintenance problems than its apparent overall value.

The alternative evaluation is presented in Table 11-2. The sources of costs used in this evaluation are listed the following bullets:

- O&M costs for Alternative 1 assume the manual bar rack is cleaned twice per year.
- Alternative 3 – Monorail and Clamshell is not considered a viable alternative by GLWA because of unfavorable experiences with this type of system at other facilities.
- Capital costs for Alternative 4 are presented in Volume 6 – Appendices, Appendix C under this project title.
- Screenings disposal costs are not included in Alternative 4 because the cost difference is so large between Alternative 2 and Alternative 4.

This evaluation shows that Alternative 2 – Remove Bar Racks is the Best Value Alternative. **As such, Alternative 2 is the Recommended Alternative.**

Table 11-2. Alternative Evaluation for Sanitary Pump Station Screen Improvements (Project OKW-SCR-1)

11.2.2 Disinfection

11.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, 10 gear pumps, and multiport injection on the discharge of the eight stormwater vertical turbine pumps. The storm pumps pump stormwater into the CSO facility and are further described in Section 11.2.12.1. Three of the sodium hypochlorite pumps are low-rate and seven are high-rate. Sodium Hypochlorite Pumps 1 through 8 inject on the discharge of Storm Pumps 1 through 8, respectively. Sodium Hypochlorite Pump 9 is a high-rate pump serving as the backup to high-rate pumps 3 through 8. Sodium Hypochlorite Pump 10 is a low-rate pump serving as the backup to low-rate pumps 1 and 2. Each pump has a VFD to adjust chemical feed flow based on storm pumping rate. Flow is metered from each pump.

Table 11-3 provides an overview of the existing disinfection system at the Oakwood CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 11-3. Overview of Existing Disinfection System at Oakwood CSO Facility

Parameter	Value
Treatment Capacity (cfs)	1,660
Design Feed Strength (% hypochlorite)	7.5

Mixers	
Number / Type	Hypo added to pump discharge
Model Number/ hp / Manufacturer	Not Applicable (Hypo added to pump discharge)

11.2.2.2 Identified Needs and Issues

The needs and issues for Oakwood were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are summarized as follows:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Oakwood chemical feed system has the following issue:
 - The gear pumps are expensive to replace and repair
 - The gear pumps vibrate despite efforts to eliminate vibration
 - The chemical feed pumps are on skids. The skid frames reduce access to the pumps and components and do not aid in the removal of the pumps.

These issues are addressed in Replace Chemical Feed System (Project OKW-DIS-1) in the following bullets.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2) in the following bullet.
- Provide ability to sample basin at two levels. The basin effluent sample pump requires the water level to reach a certain level before chlorine residual can be determined. There is concern that it could be too late to adjust the sodium hypochlorite feed rate in response to variable influent conditions affecting chlorine demand by not being able to sample sooner. Therefore, it is desired to sample at two levels, one at low level in addition to the high level at end of basin. It should be noted that this capability will be provided in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2) by installing a new pump well upstream of the effluent end of the CSO basins. As such, a separate capital improvement is not needed to address this issue.
- Feed piping overpressure alarms. There is a pressure sensor and associated alarm setpoint on the discharge of each pump. Over-pressurization alarms occur indicating the need to investigate whether the pressure relief valves are functioning properly or whether the pressure sensor is causing false alarms.

This should not be an issue after the chemical feed system is replaced, as recommended in the following bullet. In the interim, however, the pressure relief valves could be investigated to verify they are functioning properly and that the pressure sensors be checked to determine if they are causing false alarms. This can be done by installing a calibrated pressure gauge on the discharge of a pump and monitoring pressure concurrently with someone monitoring SCADA for an alarm. GLWA maintenance staff could perform this investigation or a mechanical contractor. Given that the system should be replaced in the near future, capital costs have not been included in this evaluation to address this issue.

- Investigate corrosion concern at chemical injection points on pump discharge. During meetings related to disinfection, GLWA expressed concern that corrosion could be occurring in the vicinity of where the hypochlorite is injected into the discharge pipes of each pump. Closed-circuit television (CCTV) results of the discharge pipes for each pump (conducted under another project) were reviewed for this evaluation. See Figure 11-1 for CCTV results from the chemical injection points of one pump (Pump 2) used to illustrate the condition. The CCTV did not show any serious corrosion. Based on these results, it is recommended to re-investigate the piping again in about 5 years.

Figure 11-1. CCTV Inspection of Oakwood Storm Pump Discharge Piping Showing Chemical Injection Points

- Provide side access manway on hypochlorite tanks for improved ease of inspection and future relining.
- Provide backup storm pump flow measurement, for when the storm pump flow meter is not working properly—this issue is addressed in the Oakwood I&C section (Section 11.2.7).

11.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project OKW-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to each discharge point (i.e., pump discharge pipe).
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 11-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.

- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on average annual costs of \$66,000 for manufacturer rebuilds and \$57,000 for GLWA on-site rebuilds (includes GLWA labor) for a total of \$123,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on rebuild of \$20,000 per pump for three pumps at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 11-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 11-4. Alternative Evaluation for Replace Chemical Feed System (Project OKW-DIS-1)

	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose using an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The storm pump flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on storm pump flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows. The sampling location would be near the influent end of the basin and near the bottom portion of the basin (to be able to measure TRC concentrations before the effluent sample point). Another sampling point can be provided at an intermediate level.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 11-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 11-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 156,000	\$ 4,860	\$ 258,496	\$ 74,926	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing. Also, provide sampling at two levels, one at low level and one at an intermediate level, in addition to the high level at end of basin.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common of CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Reline and Provide Side Access Manway on Hypochlorite Tanks (OKW-DIS-3). The hypochlorite storage tanks lack side entry manways making FRP repair significantly more difficult. A side entryway manhole near the bottom of each existing tank is recommended. This should be performed when the tank requires relining or a major repair. To determine the condition of the tanks, Jacobs reviewed a 2020 inspection by GHD and found that there was a only a small chip on the exterior of one tank and evidence of leakage from a drain valve (exterior to the FRP tank and not part of the tank).

Based on the limited extent of any defects to the existing tanks, it is recommended that the installation of the manways be done when the tanks near the end of their useful life and require relining. The costs for relining and adding manways to the existing tanks are included in the capital costs for this project. There is no alternative to this option. Table 11-6 provides the summary of **Reline and Provide Side Access Manway, which is the recommended alternative.**

Table 11-6. Alternative Evaluation for Reline and Provide Side Access Manway on Hypochlorite Tanks (OKW-DIS-3)

11.2.3 Odor Control

11.2.3.1 Description of Existing System

There are three odor control systems at the Oakwood facility. One system, located in the Odor Control Building next to the sanitary pump station, treats air from the east and west storm wet wells, the sanitary wet wells, and the sanitary pump station room. The second and third systems, both located in the Basin Odor Control Building, treat air from the East and West Retention Basins. Each of the retention basin odor control systems also serves the headworks, as it is connected to both CSO basins.

The system serving the pump stations consists of a grease filter/mist eliminator, an odor control fan, and a single bed vertical activated carbon vessel. The system also includes a bypass ventilation fan, which allows foul air to be removed from the pump stations and bypass the carbon column. Carbon is replaced through the top access hatch on each vessel.

The systems serving the retention basins operate in parallel. Each system consists of an odor control fan and an activated carbon vessel (there are no grease filter/mist eliminators). Each system also has a bypass ventilation fan.

These odor control systems operate under air permit requirements (Permit to Install No. 91-06). The emission limit for the Pump Station system is 0.0043 pounds per hour (pph) of hydrogen sulfide. At a design air flow of 30,000 cfm, this equates to approximately 0.028 parts per million volume (ppmv) concentration of hydrogen sulfide. The emission limit for the CSO basin systems is 0.0031 pph. At a design air flow rate of 22,000 cfm (each), this equates to approximately 0.028 ppmv concentration of hydrogen sulfide. The carbon is tested for remaining bed life on a quarterly basis as required by the permit. Carbon was replaced in all three carbon vessels in Spring 2018, which was the first time it was replaced since it was put into service in 2012.

Per GLWA, no odor complaints have been received for at least the past three years.

11.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- Improve odor control for the sanitary pump station.
- Provide improved access and safety for carbon replacement for both the sanitary and basin scrubbers.
- Provide improved access and safety for carbon sampling for both the sanitary and basin scrubbers.
- West basin odor control fan was out of service due to vibration. Vibration monitoring was not installed properly resulting in frequent fan shutdown when vibration is not excessive.

These issues are discussed below.

Oakwood HVAC Improvements Project (CIP No. 260619). The Oakwood HVAC project, currently in the design stage, will include 1) improvements to odor control for the sanitary pump station; 2) improvements for access and safety for carbon replacement for both the sanitary and basin scrubbers; and 3) improvements for access and safety for carbon sampling for both the sanitary and basin scrubbers. Capital costs are not provided because this is an ongoing project.

Vibration Sensor Modifications. Install vibration monitoring closer to the frame of the fan. This will be done as part of the Oakwood HVAC Improvements (CIP No. 260619).

11.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement “needs”.

11.2.4 Flushing and Dewatering

11.2.4.1 Description of Existing System

Dewatering System: The Oakwood screening facility and CSO basins (East and West) are largely dewatered by gravity through drain lines that discharge to the NWI force main. The CSO drain system has sufficient capacity to allow both CSO basin drain valves to be opened simultaneously; however, there is a flow control valve and magnetic flow meter provided on the drain line to the NWI to control the flow to the NWI to prevent overflows in the collection system between the CSO Basin and the WRRF. Also, there is a Surge Chamber on the gravity drain lines that will direct flow back to the head of the plant if the basin dewatering flow rate exceeds the available capacity in the line to the NWI.

Due to system hydraulics, the water in the lowest levels of the basins that cannot be discharged to the NWI by gravity is instead routed back to the Oakwood Pump Station, where flow is pumped by the sanitary wastewater pumps to the NWI.

Flushing System: A flushing gate system is used for cleaning solids from the floor of the basin following dewatering. There are 20 total flushing gates—eight in each of the two CSO basins, and two in each of the two basin influent channels. The flushing gates in each basin are arranged in two groups of four. The flushing gates operate in a latch-unlatch manner and are controlled by a common hydraulic power pack.

The flushing reservoirs are filled as the basins fill during a wet weather event. When the basin and screening facilities dewater, flushing water remains behind the flushing gates. Flushing is initiated by sequentially unlatching two basin flushing gates (one in each basin) at a time in the first basin reservoir until all are open. Then, if the last of the four reservoirs was full prior to its gate opening, the second set of flushing gates will sequentially open. Once basin flushing is completed, one gate is opened in each influent channel. The flushing sequence only allows one gate in each channel to be open at a time.

Table 11-7 provides an overview of the existing flushing and dewatering system at Oakwood CSO facility.

Table 11-7. Overview of Existing Flushing and Dewatering System at Oakwood CSO Facility

Parameter	Value
Total Basin Volume (MG)	9
Headworks and Basin Dewatering and Flushing System	- Basins are dewatered by gravity by opening the Drain Valve to the NWI - There are 20 flushing gates; 8 in each basin and 2 in each basin distribution channel - Flushed solids are routed to the Oakwood Pump Station for pumping to the NWI

11.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Air-operated pinch valve intended to isolate the two sides of the Storm Pump Station during dry weather are encased in sand, making them extremely difficult to access, and the air lines that actuate them are underground and have a leak, which cannot be found.
- Flushing valves are hard to reach during maintenance activities and scaffolding needs to be setup to reach the valves, which is difficult due to steep slope on the floor
- Significant grit accumulation at the flushing sumps in the basin leads to plugging of the 12-in. drainage pipeline at the effluent end of the basin

11.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Influent Junction Chamber Isolation (Project OKW-FD-1). The existing influent chamber has two 18-ft diameter sewers from the junction chamber to the Oakwood Storm Pump Station. Within the junction chamber, at the bottom of each 18-ft diameter pipe, there is a 30-in. diameter pipe with an air-operated pinch valve intended to isolate the two sides of the Storm Pump Station during dry weather. These pinch valves are encased in sand, making them extremely difficult to access, and the air lines that actuate them are underground and have a leak, which cannot be found. As such, they have not been repaired after they failed. A means to isolate the two sides of the Storm Pump Station is still needed. A previous study (Oakwood CSO Pump Station Investigative Study, Brown and Caldwell, January 15, 2019) identified several alternatives that included replacement of the existing pinch valves and new stop logs. Jacobs reviewed this study and discussed cost effective options with GLWA. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Contractor to install isolation, when needed.
- 2) **Alternative 2: Influent Junction Chamber Isolation Improvements.** This alternative includes removal/replacement of the existing dry weather flow pinch valves with new small hand-pull slide gates. Figure OKW-FD-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the conceptual layout of this improvement. Following removal of the pinch valves and demolition of the concrete boxes, brackets for a 36-in. by 36-in. hand-pull slide gate will be mounted on the rehabilitated concrete face of the 30-in. pipe in each channel. The hand-pull gates (two service and one spare) could be stored in the upper part of this structure. Flow bypassing is assumed during modifications.

This project should be coordinated with the NWI Diversion project to coordinate and minimize shutdowns and bypass pumping requirements.

The alternative evaluation for these alternatives is presented in Table 11-8. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 includes the estimated cost of isolation, which is based on \$60,000 per event and frequency of use is assumed to be once every 5 years, for an annual O&M cost of \$12,000.
- The O&M costs for Alternative 2 includes the estimated cost of isolation, which is based on \$2,000 per event and frequency of use assumed to be once every 5 years, for an annual O&M of \$400.

The total benefit score for Alternative 2 is about 0.8 greater than Alternative 1. Also, the NPV/Benefit cost for Alternative 2 is less than Alternative 1. As such, **Alternative 2 - Influent Junction Chamber Isolation Improvements is the recommended alternative.**

Table 11-8. Alternative Evaluation for Influent Junction Chamber Isolation (Project OKW-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.58	\$ -	\$ 12,000	\$ 253,076	\$ 97,965	
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Unable to isolate the two sides of the Storm Pump Station during dry weather.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Influent Junction Chamber Isolation Improvements	Health and Safety	3	3.42	\$ 289,000	\$ 400	\$ 297,436	\$ 87,054	Best Value Alternative
	<i>Definition:</i>	Removal/replacement of the existing dry weather flow pinch valves with new small hand-pull slide gates.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Simple system to isolate storm pump wet well.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Still requires manned entry into junction chamber, when needed	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Reservoir Flushing Valves and Basin Sump Flushing (Project OKW-FD-2). The O&M staff noted that the flushing valves are hard to reach during maintenance activities and scaffolding needs to be setup to reach the valves, which is difficult due to steep slope on the floor.

O&M staff also report that significant grit accumulation at the flushing sump leads to plugging of the 12-in. drainage pipe at the effluent end of the basin. Frequent jetting of this pipe is difficult due to the configuration of the pipes below the facility's slab and the depth to the flushing sump below the adjacent finger weir. There are also two 10-in. drain lines on the influent end that plug, but at a lesser frequency.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Continue to jet-rod the pipe, when necessary.
- 2) **Alternative 2: Reservoir Flushing Valves Relocation and Basin Sump Flushing.** This alternative relocates the reservoir flushing valves and piping to downstream of flushing gates, where the slope of the floor is less steep. Figure OKW-FD-2-ALT-2 in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

Improvements to mitigate the pipe clogging include installing submersible solids handling pumps (4-in. discharge) at each sump to recirculate effluent near the sump drains and resuspend accumulated materials. A 4-in. ductile iron discharge manifold mounted around the sump with two or three nozzles pointed toward the sump opening would support more complete resuspension while the basin is use. See Figure OKW-FD-2-ALT-2 in Volume 6 – Appendices, Appendix B for conceptual illustration. As the facility comes into operation, the pumps would start operating and continue operation for the duration of the event and as the facility is drained. By preventing a large accumulation at the sump, the draining process can more effectively dewater the facility and gradually remove settled materials. Pumps would be rail-mounted and removable to the surface through new hatched openings in the top of the structure.

The alternative evaluation for these alternatives is presented in Table 11-9. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M cost for Alternative 1 includes the estimated cost of setting up scaffolding and jetrodding. The cost of scaffolding is based on \$15,000 per event and frequency of use to be once every 10 years. The cost of jetrodding is based on \$10,000 per event and frequency of use to be once every year.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 2 includes the estimated cost of setting up scaffolding. The cost of scaffolding is based on \$10,000 per event and frequency of use to be once every 10 years.

The total benefit score for Alternative 2 is two times higher than Alternative 1 because of the significant improvement to health and safety and ease of operation. Although the NPV/benefit cost is slightly higher for Alternative 2, the type of improvements make **Alternative 2 - Reservoir Flushing Valves Relocation and Basin Sump Flushing the recommended alternative.**

Table 11-9. Reservoir Flushing Valves and Basin Sump Flushing (Project OKW-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	1	2.00	\$ -	\$ 11,500	\$ 242,531	\$ 121,265	Best Value Alternative
	<i>Definition:</i>	Continue to jet-rod the pipe, when necessary.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Difficult to set-up scaffolding in basin to reach valves. Unsafe conditions for jetrodding drain line	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Reservoir Flushing Valves Relocation and Basin Sump Flushing	Health and Safety	5	4.00	\$ 536,000	\$ 1,000	\$ 557,090	\$ 139,272	
	<i>Definition:</i>	Relocate the reservoir flushing valves (RFVs) and piping to downstream of flushing gates and install sump flushing system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier to reach RFVs for maintenance; Sump flushing system should eliminate need to access basin when it is partially filled to jet-rod drain lines.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher capital cost.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

11.2.5 HVAC

11.2.5.1 Description of Existing System

The Oakwood CSO facility consists of three buildings. The main building contains the Storm Pump Station, Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, MAU room and hydraulic room. The Basin Odor Control Room contains the odor control systems for the East and West Basins. Table 11-10 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, gas-fired water heater, emergency shower/eye wash, emergency eye wash, sump pumps, pressure booster pumping system, compressed air system etc. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 11.2.10.

Table 11-10. Major HVAC Equipment at Oakwood CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Main Pump Station	SF-1 to 2	Supply Fan	5,000 CFM
Headworks	MAU-3	MAU	35,800 CFM 3,000 MBH
Basin	EF-20 to 22	3 × Exhaust Fan (East Basin)	52,800 CFM
	EF-23 to 26	3 × Exhaust Fan (West Basin)	52,800 CFM
	SF-5 to 7, SF-10	4 × Supply Fan (East Basin)	52,800 CFM
	SF-5, SF-8 to 10	4 × Supply Fan (West Basin)	52,800 CFM
Chemical Room	AC-2	Air Conditioning Unit	315 CFM 1.25 ton
	MAU-4	MAU	5,000 CFM 400 MBH
	EF-18	Exhaust Fan	2,500 CFM
Electrical Room	AHU-1	AHU	25,000 CFM, Cooling Capacity (125 tons), Heating Capacity (353 MBH)
	EF-35	Exhaust Fan	13,880 CFM
	EUH-8	Electric Unit Heater	1,700 CFM 15 KW
Mechanical Room	AHU-1A	AHU	2,700 CFM
Make-up Air Room	MAU-3	MAU	35,800 CFM
Odor Control Room	EF-28, EF-29	Exhaust Fan	3,000 CFM
	EF-33, EF-34	Exhaust Fan	22,000 CFM
	EUH-6 to 7	Electric Unit Heater	1,700 CFM 15 KW

Table 11-11 provides a summary of the basis of design performance criteria for HVAC systems at Oakwood and Table 11-12 provides the outdoor Basis of Design conditions.

11.2.5.2 Identified Needs and Issues

During the CS-299 Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- Insufficient heating capacity in Headworks Area (served by MAU-3): Upon further investigation, the assessment of insufficient heating was based on the fact that a NPW pipe to one of the screens had burst during a cold period last year. It was determined that this issue was related to a problem with the booster pump system.
- Failed Basin supply air fans and exhaust air fans require replacement: this issue is part of the ongoing HVAC Improvements project (CIP No. 260619).

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- AHU-1 compressor failures: GLWA's HVAC contractor noted that there have been 4 compressor failures with the AHU-1 DX cooling coil in the past 5 years.
- Abnormally short life of Electric Unit Heaters: Per GLWA's HVAC Contractor, the Trane Electric Unit Heaters at Oakwood have a life of 2 to 3 years. The typical expected life of unit heaters that are properly selected for their environment is about 15 years.

Jacobs investigated this issue further. The Trane UHXA unit heaters in the Headworks Area have an aluminum-finned tubular steel heat exchanger that is directly exposed to the air stream in the Headworks Building when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating that has passed the ASTM International Standard B117 salt-spray test. As such, this issue should be covered in the SRP.

- Failed Basin supply air fans, maintenance issues, and signs of advanced wear: Several basin supply air fans have failed. There have been bearing failures in the units but there is no access for bearing maintenance. The bearings are greased remotely but there is no way to verify if the grease is getting to the bearings. Despite the fact the units are only 10 years old, the bodies of the units are showing advanced signs of age. GLWA's HVAC contractor does not believe the bases of the units were properly installed; however, the manufacturer provided an inspection in 2020 and concluded that the apparent base settlement was not a concern. As noted above, these fans are being replaced as part of the HVAC Improvements project (CIP No. 260619).

During site investigations (June 2020), the following observations were noted:

- AHU-1 only had one compressor running: Although the weather on the day of the site visit was hot and humid, only one compressor was observed to be running. This underscores that most of the cooling load is driven by the heat generated by electrical equipment, which was not in service on the day of inspection. The main contributors to the cooling load in the space are the VFDs for the stormwater pumps, which rarely run. Jacobs confirmed, however, that the cooling capacity is correctly sized for the predicted heat generated by the electrical equipment when it is in service.
- MAU-4 for the Chemical Room has a complex burner control scheme: Heating output is controlled on MAU-4 by relay packs on each burner. This system is overly complicated and maintenance intensive as each relay represents a potential failure point in the system. GLWA's HVAC contractor noted that they recently had to replace the controller on the unit.

When MAU-4 fails or if maintenance issues become too costly, Jacobs recommends replacement of the unit with one that has a simpler mechanism to modulate the burner output. More efficient units with simpler control schemes are currently available. As such, this issue will be covered in the SRP.

- The Electrical Room was negatively pressurized: The Electrical Room has differential pressure control; however, the area was noted to be negatively pressurized. Electrical rooms are typically positively pressurized to reduce the ingress of dust and corrosive gases into the space. At some facilities, the incoming outside air is filtered with an activated carbon unit to remove H₂S and other corrosive airstream gases.
- MAU-1 has extensive corrosion: Extensive corrosion was noted on the interior of MAU-1. This is most likely the result of backflow of air from the Sanitary Pump Station Room. This MAU is being addressed under the ongoing HVAC Improvement project (CIP No. 260619).

11.2.5.3 Description and Evaluation of Alternatives

As noted above, the major existing HVAC issues and needs are being addressed by the ongoing HVAC capital improvement project. One issue remains and is discussed below. At this time, it is believed that this issue does not require a capital improvement.

AHU-1 Compressor Issues. The extremely high frequency of compressor replacement would suggest that AHU-1 is experiencing abnormal equipment operation. Given the dependence of the peak cooling load on stormwater VFD operation, which occurs rarely, it is likely that the compressors are short-cycling. Jacobs recommended monitoring the compressors using current transformers to determine if this is occurring. As a result of this recommendation, GLWA's mechanical contractor installed a monitoring system in August 2020. Based on review of this data, Jacobs observed that only one of the four compressors (Compressor No. 3) was operating and that it experienced occasions with extremely short cycle times where it was off for less than a minute or only ran for a minute. During the site walkthrough Jacobs noted a compressor was running when the temperature in the electrical room was 75°F despite the fact that the specified sequence of operations calls for AHU-1 to run only if the space temperature exceeds 87°F and that the sequence of operations calls for free cooling to be provided by outside air between a space temperature of 75°F and 87°F. Because AHU-1 was not operating in accordance with the sequence of operations, Jacobs recommended resetting AHU-1 to original factory settings as a next step to potentially reduce short cycle times.

Resetting the AHU did not result in a reduction in short cycle times. Jacobs then contacted Trane, which advised that minimum compressor runtimes and lockout times could be programmed into the unit.

As next steps Jacobs advises GLWA to:

- 1) Work with the mechanical maintenance provider to ensure AHU-1 is functioning as intended per the sequence of operations. As noted above, AHU-1 should economize before running any compressors.
- 2) Verify the cooling temperature setpoint in the space to determine if it has been set to an unreasonably low temperature (outside of the sequence of operations). If the temperature setting is lower than design, Jacobs recommends limiting which users can adjust the cooling setpoint.
- 3) Work with their mechanical maintenance provider to program the unit's compressors to run for a minimum of 15 minutes followed by a minimum lockout time of 15 minutes.

11.2.6 Electrical

11.2.6.1 Description of Existing System

The Oakwood facility's electrical system consists of double ended 4.8 kV, 3,000 A switchgear with dual (redundant) utility feeds, metering of the 4.8 kV feeds and an adjacent DTE substation with two 15 MVA outdoor transformers. The switchgear has a tie-breaker and automatic source transfer controls. Circuit breakers in the switchgear then feed eight storm pumps and two 2,500 kVA outdoor pad mount transformers. The 2,500 kVA transformers then feed a double ended 480 V, 3,200 A switchboard with a key interlocked tie-breaker. Circuit breakers in the switchboard then feed four MCCs and four 125 hp sanitary pumps. The MCCs then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 11-13 provides a summary of the major electrical equipment for this facility.

Table 11-13. Major Electrical Equipment at Oakwood

Location	Major Electrical Equipment	Description
Electrical Room	Double ended 4.8 kV switchgear w/ automatic source transfer	3,000 A, 4.8 kV, 3-Phase
Electrical Room	VFD (Storm Pumps)	(4) 4.8 kV, 3-Phase
Storm Pump Motor Room	Vertical turbine pumps	(2) 1,500 hp, (6) 2000 hp, 4.8 kV, 3-Phase
Outdoors	Pad Mount Transformers	(2) 2,500 kVA, 4.8 kV-480 V, 3-Phase
Electrical Room	Double ended switchboard w/ tie-breaker	3,200 A, 480 V, 3-Phase
Electrical Room	VFD (Sanitary Pumps)	(4) 480 V, 3-Phase
Sanitary Pump Room	Sanitary Pumps	(4) 125 hp, 480 V, 3-Phase
Electrical Room	MCC-1	1,200 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-3	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-4	1,200 A, 480/277 V, 3-Phase

11.2.6.2 Identified Need and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

11.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project OKW-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure OKW-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Near drain vaults and effluent end of Basin – Add LED lighting fixtures to meet the required foot-candles per IES standards and meet the requirements of the local outdoor lighting ordinances for the areas.
 - Interior Basin at effluent channel – Add interior LED ceiling and wall mounted lighting fixtures within the area to address the required foot-candles and code requirements.
 - External lighting on top of Basin - Add additional light poles and LED lighting fixtures on the facility's basin, lighting foot-candles will meet the requirements of the local outdoor lighting ordinances.
 - Add power receptacles every 100 ft around the exterior of the basin at ground level.
 - Add power receptacles on the top of the basin.

The alternative evaluation is presented in Table 11-14. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$75,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 11-14. Alternative Evaluation for Electrical Improvements (Project OKW-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Add additional lighting near drain vaults and effluent end of basin, interior basin at effluent channel, and top of basin; add power receptacles to assist workers.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

11.2.7 I&C

11.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2012 under PC-755. In 2015 under PC -773D, the Ovation control system controllers and software were upgraded to version O.V.3.5.0.

The existing Ovation system includes remote I/O cabinets located in the Headworks/CSO Basins that are networked to the Ovation controller/I/O cabinets and data concentrator cabinet located in the Communication Room. The system currently has one dual screen operator workstation, plus a database server with wall mounted displays and printers in the Control Room. The Ovation redundant pair of controllers provides the facility with a redundant network, controls and I/O capabilities. A 10 kVA Liebert uninterruptible power supply is used to provide constant power to the Ovation system and network. The Ovation network is equipped with primary and backup network switches. The switches are connected to the GLWA AT&T wide area network via the facility's router. The network connections inside the station are via copper Ethernet cables. All workstations and controller connections have redundant networks. The controller connections are dual-homed to provide system redundancy. Should one network fail, the backup, redundant network is available to provide station monitoring and control. The Ovation system is equipped with a backup radio system to communicate critical monitoring points back to the SCC on wide area network failure.

Flow and Level Sensors: Table 11-15 summarizes the level sensors and flow meters at the Oakwood CSO Facility and Sanitary Pump Station for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 11-15. Summary of Flow Meters and Level Sensors at Oakwood CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Storm Pump Flow Meters	8	Area Velocity
Drain to NWI Meter Vault	1	Magnetic
CSO Facility Level Sensors

<i>Sanitary Pump Station Level Sensors</i>		
Sanitary Wet Wells (East and West, Upstream and Downstream)	4	Ultrasonic
Sanitary Surge Relief Chamber	1	Ultrasonic

11.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Operators have indicated the human interface modules (HIMs) for the Chemical Feed Pump VFDs are difficult to operate locally.
- Eliminate basin gas monitoring.
- Minimize fire alarm systems. Elimination of fire alarm systems is not recommended at Oakwood based on the discussion in Section 5.4.7.
- Need for tank level indication at the Chemical Fill Station
- Need for process cameras at select locations to improve monitoring of facility during wet weather operation.
- Update Ovation control system
- Investigate cause of storm pump flow meter failures. Jacobs further investigated this issue. The storm pump flow meters (Teledyne Isco Inc Pro20 HotTap Insertion Meters) have experienced frequent, random outages. Jacobs investigated the issue with the manufacturer Teledyne and with technicians from PCI, who had investigated these meters. According to the Teledyne Isco Inc Pro20 HotTap installation instructions, the meter is suitable for a wide range of pipe sizes, pipe geometries, and varying hydraulic conditions. All of these installation conditions are met, which indicates the meter is being used in the proper application, but an underlying issue is still present, which is causing the random outages. In order to determine the root cause of the issue, a deeper evaluation from an instrumentation contractor familiar with these meters will be required. An allowance of \$50,000 is included in the capital cost estimate to further study this issue.
- Investigate backup flow measurement for each storm pump if the flow meter is not working properly. GLWA requested that Jacobs consider as a backup creating a programmed lookup table to estimate flow based on wet well level and pump curves. Jacobs discovered that this type of backup flow measurement was actually specified to be programmed into the control system according to the 2007 contract documents (Specification 17500 page 12) and may already exist in the software. If it is not included, it could be added by a controls system contractor. Based on this information, a capital improvement is not provided to address this issue.

11.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

I&C Improvements (Project OKW-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation

Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) **Alternative 1: Do Nothing/ Replace In-Kind**

- Replace Storm Pump flow meters in-kind
- Leave HIM modules for the Chemical Feed Pump VFDs in place

2) **Alternative 2: I&C Improvements** including,

- Improve local operation capabilities of chemical feed pump HIM
- Eliminate basin gas monitoring
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations
- Resolve existing storm pump flow meter reliability issues

Each of the I&C related improvements listed above is described further below:

Improve local operation capabilities of chemical feed pump HIM. Operators have indicated the HIMs for the chemical feed pump VFDs are difficult to operate locally. The buttons are small and navigating through the LCD screens is not intuitive or easy to use. The recommendation is to provide local control stations similar to the approach to add local control in Section 5.4.9. The VFD HIM modules would remain for troubleshooting, but operation of the chemical feed pumps will be from the local control stations.

Eliminate basin gas monitoring. Eliminate gas monitoring equipment in accordance with Section 5.4.7.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Resolve existing storm pump flow meter reliability issues. This issue should be further investigated by an instrumentation contractor.

The alternative evaluation is presented in Table 11-16. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 includes replacement of the Storm Pump flow meter.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 2 include estimated annual O&M for the new cameras and new tank level indicators.

This evaluation shows that Alternative 1 – Do Nothing is the Best Value Alternative. **However, because of the improved reliability, control and operations associated with the I&C improvements, Alternative 2 is the recommended alternative.**

Control System Upgrade (OKW-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 11-17 provides the summary of the **Control System Upgrade, which is the recommended alternative.**

Table 11-16. Alternative Evaluation for I&C Improvements (Project OKW-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.40	\$ 145,600	\$ -	\$ 145,600	\$ 60,667	Best Value Alternative
	<i>Definition:</i>	Replace Storm Pump flow meter in-kind.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to operation - flows and volumes, alarms, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.60	\$ 347,000	\$ 8,000	\$ 515,717	\$ 143,255	
	<i>Definition:</i>	Improve local operation capabilities of Chemical Feed Pumps; eliminate basin gas monitoring; provide tank level indication; and provide process cameras.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Higher performance, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Table 11-17. Alternative Evaluation for Control System Upgrade (Project OKW-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,003,000	\$ -	\$ 1,003,000	\$ 334,333	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Replace Sample Building local control panel. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Updates the control system to allow for enhanced performance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.8 Site

11.2.8.1 Description of Existing Site

Access to the site is off Pleasant Street through a 26-ft wide sliding vehicular gate. The parking lot consists of 8-in. thick reinforced concrete pavement. Roads onsite consist of 26 ft wide, 9 in. thick reinforced concrete pavement with 8-in. aggregate base designed to support HS-20 loading. There is also a gravel road going around the basin building consisting of 8 in. of aggregate. Concrete sidewalks are 4 to 5 ft wide and 4 in. thick with a 2-in. sand base. Site security is provided by a perimeter fence comprised of an 8-ft ornamental iron fence and an 8-ft chain-link fence. Stormwater runoff from the site is collected and conveyed to the storm junction chamber upstream of the pump station.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's geographic information system (GIS). Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GP) date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

11.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the following bullets.

- The current road around the basin is gravel and susceptible to potholing .
- There are areas around the basin with poor drainage, including electrical and instrumentation vaults.
- There are several locations around the perimeter of the Control Building where the concrete access sidewalk has settled, leaving uneven cracked flags of sidewalk.
- The following needs are generally preventative maintenance items intended to ensure that the site features or utilities are serviceable throughout their expected service lives.
 - Clear vegetation overgrowth from Surge Relief Basin
 - Seal joints in concrete pavement drive to ensure serviceability

11.2.8.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project OKW-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Site Improvements** including,

- Add paved road around the basin
- Address drainage around the basin
- Address drainage in electrical and instrumentation vaults
- Replace settled concrete sidewalk

Each of the site related improvements listed above is described further below:

Add Paved Road Around the Basin. The access service road around the perimeter of the Control and Pump Station Buildings includes reinforced concrete pavement and gutter. However, the access road around the CSO basin is a gravel surface. A number of areas around the perimeter of the basin have experienced poor drainage, that has impacted the service drive, resulting in potholing and reducing accessibility around the CSO basin. It is recommended that the gravel service road be replaced with new reinforced concrete pavement that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. See Figure OKW-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the location of new pavement. The concrete pavement should have a minimum 16-ft width.

Address Drainage Around CSO Basin. There are areas around the CSO basin that are poorly drained. Runoff from the CSO basin roof is collected at six scupper/downspout locations on either side of the basin and discharged to grassy areas at grade between the basin and service road on either side of the basin. These areas do not have significant slope, so basin roof discharge during wet weather tends to accumulate at grade at the base of the basin. The west side of the basin is particularly poorly drained. This may be an area that could benefit from a Green Stormwater Infrastructure solution that would feature a bioswale to collect runoff from the poorly drained grassy area between the basin and service drive. On the basin's west service drive, there is a shallow drainage swale with dimensions of approximately 360 ft by 30 ft. The area tributary to this swale includes areas surrounding its immediate perimeter.

It is recommended that the swale be excavated to increase its volume to accept the flow that is discharged from the west side of the basin roof during wet weather. Figure OKW-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, presents the proposed layout for these improvements. The flat area between the basin and existing service drive is recommended to be regraded away from the basin, and new catch basins and a storm sewer be added to capture the surface runoff and direct the flow under the service drive to discharge into the new bioswale.

Address Drainage in Electrical and Instrumentation Vaults. In the past, the basin electrical/I&C vaults on the west side of the basin had experienced flooding through electrical conduits, allowing groundwater to flow into the vaults. Per discussion with GLWA, the damaged duct-banks have been replaced and the issue of water infiltration into the vaults has been fixed. Having inspected the ground surfaces around the basin, this area should be regraded and the top of the vaults should be adjusted to avoid any surface drainage from going into these vaults. If there is still infiltration into these vaults and there is a desire to keep them free of water, a permanent sump pump should be installed in each vault.

Replace Settled Concrete Sidewalk. There are several locations around the perimeter of the Control Building where the concrete access sidewalk has settled, leaving uneven cracked flags of sidewalk. It is recommended that the damaged sections of sidewalk be removed and replaced to mitigate the potential tripping hazard created by the uneven surfaces. Expansion joints at the base of the building wall should be replaced and caulked to prevent water infiltration.

The alternative evaluation is presented in Table 11-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Site Improvements has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$209,000, which is a moderate cost compared to other projects recommended in this assessment. However, because of the improved drainage and safety with **Alternative 2 – Site Improvements, Alternative 2 is the recommended alternative.**

Table 11-18. Alternative Evaluation for Site Improvements (Project OKW-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Potholing of gravel road; ponding water around basin; submerged electrical and instrumentation vaults; settled sidewalk.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 732,000	\$ -	\$ 732,000	\$ 209,143	Not Applicable
	<i>Definition:</i>	Replace gravel road with new reinforced concrete pavement around the basin and improve drainage around CSO Basin and drainage into electrical and instrumentation vaults. Replace settled concrete sidewalk.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Smoother road; proper drainage around basin and better access to vaults.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

11.2.9 Architectural

11.2.9.1 Description of Existing Facilities

The Oakwood facility consists of chemical room, utility support (electrical and mechanical), control room, odor control room, screen room, sampler room, storm pump room, sanitary pump room, hydraulic room, make-up air room, shipping and receiving and miscellaneous other rooms. The facility also includes the retention basins.

11.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/coverings systems
- Stairways
- Corrosion on visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

11.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (OKW-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Remove failed concrete floor coating, clean floor and reseal floor in Headworks and Odor Control Rooms

- Clean rust/ corrosion and coat localized areas in roof framing and beams in the Sanitary Pump Station and Headworks
- Clean and coat corroded areas of vehicle barriers and bollards
- Investigate and repair cause of water intrusion at skylight, between roof decking and skylight installation
- Remove and replace various door hardware and address corrosion on door hardware
- Clean and coat debonding paint from wall
- Clean corrosion of column base plate and apply moisture resistant coat in Pump Station Odor Control Room
- Fasten and replace damaged face brick façade flashing

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure OKW-ARCH-1-ALT-2).

The alternative evaluation is presented in Table 11-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 11-19. Alternative Evaluation for Architectural Rehabilitation (Project OKW-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 880,000	\$ -	\$ 880,000	\$ 283,871	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.10 Safety

11.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

11.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 11-20. The capital improvement project to address these issues is included in the table.

Table 11-20. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Storm Pump Station	Stairway to lower level has excessive gap at landing	Extend railing	Safety Improvements (Project OKW-SAFE-1)
Top of basin	Conduit posing a trip hazard (multiple locations)	Install conduit ramps	Safety Improvements (Project OKW-SAFE-1)
Storm Pump Station lower level	No eyewash and shower present on this level, yet there are containment jugs for hypochlorite, one of which was full and had recently overflowed onto the floor	Add eyewash and shower	Safety Improvements (Project OKW-SAFE-1)
Effluent Sample Room	Eyewash is out of service	Replace eyewash	Safety Improvements (Project OKW-SAFE-1)
Sanitary Pump Room	Illuminated exit sign not working	Replace exit sign	Exit Sign Improvements ^a
Basin Odor Control Room	Illuminated exit signs not working	Replace exit signs	Exit Sign Improvements ^a
Chemical Room	Gaps between ladder and tanks 1 and 2 at top of ladders are too large	Install step platform	Safety Improvements (Project OKW-SAFE-1)
Storm Pump Station	Gaps between ladder and motors at top of ladders are too large	Install step platform	Safety Improvements (Project OKW-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

11.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project OKW-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing on the stairway in the Storm Pump Station to eliminate fall hazard
- Install conduit ramps at the top of basin to eliminate trip hazard
- Replace eyewash/shower in the Storm Pump station, Effluent Sample Room, and Sanitary Pump Room
- Install step platform between ladder and tanks 1 and 2 at top of the ladder in the Chemical Room

- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency, the Table 11-21 showing the one alternative is presented below.

Table 11-21. Alternative Evaluation for Safety Improvements (Project OKW-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 338,000	\$ -	\$ 338,000	\$ 112,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address tripping hazards, fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Oakwood CSO Facility.

11.2.12 Storm Pump Station

11.2.12.1 Description of Existing System

The storm water pump station consists of eight vertical mixed flow pumps. Design criteria is presented in Table 11-22. The pump station is divided into two equal sized wet wells. Each wet well contains one smaller pump and three larger pumps. The storm pumps are equipped with an external flushing water system for bearing cooling and lubrication. The seal water system consists of potable water piping with a dedicated seal water booster pump for each storm pump. As the wet wells fill, the storm pumps start based on the wet well levels and control system logic. The station was designed for operation using a constant-level control strategy. Features of this control strategy include narrow wet well operating range, pump speed ramping up and down, and pumps turning on/off to match a set level. This requires pumps with VFDs and a high degree of turn-down capability for the pumps.

Table 11-22. Design Criteria for Oakwood Storm Pump Station

Storm Pump No.	Design Capacity, MGD	Total Dynamic Head, ft	Drive Type
1 and 2	97	48	VFD
3, 4, 7, and 8	178	48	Constant Speed
5 and 6	178	48	VFD

11.2.12.2 Identified Needs and Issues

For the Storm Pump Station, Jacobs examined existing conditions and obtained information from O&M staff members. Many of the stormwater pumping issues were evaluated separately in a report by Brown and Caldwell dated January 15, 2019. Jacobs confirmed in June 2020 that it appeared the recommendations for the stormwater pumps had not yet been implemented.

SP1 and SP2 (small pumps) were found to have an unstable operating zone below 60 MGD at typical wet well levels and motor speeds below approximately 85 percent. Currently, the majority of SP1 and SP2 operating time is at a motor speed of 75 percent within this unstable zone. SP5 and SP6 have an unstable zone below 110 MGD (motor speeds below 80 percent). SCADA data documents significantly increased pump vibration levels and rapidly fluctuating discharge flowrates while operating in this unstable zone. Pump operation outside of the preferred operating range (POR) and especially in the unstable zone will lead to diminished reliability. Anticipated consequences include increased rate of failure of bearings and seals. The low annual runtime of the pumps may mask reliability issues related to the poor operating conditions. The recommended discharge-flowrate turn-down range for SP1, SP2, SP5 and SP6 is significantly less than the original design intent. Pumps SP3, SP4, SP7, and SP8 operate in a stable zone at all normal operating conditions.

The storm pumps operate within a narrow range of wet well levels. The pump net positive suction head (NPSH) margin was analyzed, and based on the analysis performed, it may be possible to start pump operations at a lower wet well level.

Based on this information, it was recommended that the operating setpoints be modified and tested. The potential setpoint modifications include the following:

- Operate SP1 and SP2 within a speed range of 85 to 100 percent to avoid unstable operating zones. Jacobs confirmed that, as of June 2020, this modification had not yet been made.
- Operate SP5 and SP6 within a speed range of 85 to 100 percent to avoid unstable operating zones. Jacobs confirmed that, as of June 2020, this modification had not yet been made for SP6.
- Lower lead pump shut-off WSE from EL 71-ft to EL 65-ft to reduce pump cycling on/off. Prior to implementing this recommendation, at a minimum, the submergence should be calculated for the large pumps using the equation in ANSI/HI 9.8 (Pump Intake Design) to determine if the proposed minimum WSE is feasible. A more robust study would be to perform physical model tests for low water level for the large storm pumps.
- For the near term, modify controls to provide continuous seal/lube water to all storm pumps to prevent clogging of seal water lines. Note that the facility SOP indicates that the "seal water system" is to be run continuously if the storm pump wet well level is above the bell of the storm pumps. Consider whether the modified controls will allow the seal water to run at a lower than advised wet well level, implications, and modifications to run seal water continuously under appropriate conditions. Jacobs confirmed that, as of June 2020, the seal water pumps run continuously.

The seal water systems for the storm water pumps were found to experience various operational issues. Previously, tripping of the seal water booster pump circuit breakers frequently caused failure of the storm pumps. This issue was addressed by replacing the breakers. Recently, the seal water lines have become plugged and proved difficult to clear. These events coincided with the blinding of bar rack in the sanitary PS. Because the racks were blinded, the sanitary sewage level in the storm wet well raised to nearly EL 70-ft. Exposure of the storm pump bearings to sanitary sewage floatables may have plugged the bearing flushing lines.

11.2.12.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Rehabilitate Storm Pumps (Project OKW-PUMP-1). This project would include removal of each pump for inspection in the factory and necessary rehabilitation of all eight storm pumps. The conversion of the water bearing lubrication system with a grease bearing lubrication system would be included to alleviate the plugging problems experienced in the past. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Continue to operate pumps in existing condition and rehabilitate at some time in the future.
- 2) **Alternative 2: Rehabilitate Storm Pumps.** This alternative includes removal of all pump rotating assemblies for inspection and rehabilitation, as necessary. The alternative also includes conversion of all pumps from a water bearing lubrication system to a grease lubrication system. This task should include: Confirm details of required modifications with pump manufacturer (Xylem/Flygt); identify the recommended type of grease; determine where the excess water for motor bearing cooling and seal water services would be conveyed (enclosing tube typically fills with grease); modifications required to seal the bottom of enclosing tube around the shaft to prevent wastewater/ grease mixing in tube; and, obtain state regulator buy-in for this modification.

This task should also evaluate and recommend the feasibility of lowering the lead pump shut-off water surface elevation from EL 71-ft to EL 65-ft in an effort to reduce pump cycling on/off. This task may require physical model tests for the large storm pumps.

The alternative evaluation for these alternatives is presented in Table 11-23. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to the importance of reliable storm pumping after the diversion of additional flow from the NWI in the near future, **Alternative 2 – Rehabilitate Storm Pumps is the recommended alternative.**

Table 11-23. Alternative Evaluation for Rehabilitate Storm Pumps (Project OKW-PUMP-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.80	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do not rehabilitate pumps	Water Quality & Compliance	3						
	<i>Adv.:</i>	Same as existing	Capacity Enhancement	3						
	<i>Disadv.:</i>	Potential pump failures (i.e., plugging of seal water lines, bearing and seal failures)	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Rehabilitate Storm Pumps with Grease Lubrication System	Health and Safety	3	3.10	\$ 4,100,000	\$ -	\$ 4,100,000	\$ 1,322,581	Not Applicable
	<i>Definition:</i>	Rehab Storm Pumps and convert water bearing with grease bearing lube system	Water Quality & Compliance	3						
	<i>Adv.:</i>	More reliable operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Regulatory concerns with grease in wastewater	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.13 Sanitary Pump Station

11.2.13.1 Description of Existing System

The Sanitary Pump Station of the Oakwood CSO Facility consists of two separate wet wells (east and west) and an enclosed sanitary pump station room located at ground level. Each wet well includes a manual bar screen and two submersible sanitary sewage pumps for a total of four pumps. Even number pumps (SN2 and SN4) are located in the east wet well, while odd numbered pumps (SN1 and SN3) are located in the west wet well.

11.2.13.2 Identified Needs and Issues

For the Sanitary Pump Station, Jacobs examined existing conditions and obtained information from O&M staff members. Many of the sanitary pumping issues were evaluated separately in a report by Brown and Caldwell dated January 15, 2019.

The manual bar screen frequently become blinded, resulting in differential water levels of 12-15 ft from upstream to downstream of the bar racks. This can contribute to submergence of the storm pump intakes during dry weather flow. This issue is evaluated in the Screening section above and removal of the bar racks is recommended.

In general, the pumps have normal annual pump runtimes. Operation of east and west wells is imbalanced due to failure of the Influent Junction Chamber isolation pinch valves. Modifications to the Influent Junction Chamber are discussed in the Dewatering and Flushing section above.

The new Flygt pumps are expected to run over a range of static head that spans wet well elevation 78 down to wet well elevation 43.6, a static head range of 34.5-ft between low wet well elevation and high wet well elevation. These pumps are operating without VFDs. The Flygt pumps operate to the right side of the best efficiency point (BEP) for most operating conditions. At low wet well elevations, the pumps operate most efficiently at approximately 83 percent speed. At high wet well levels, the pumps run well to the right of the POR (nearly off of pump curve) under all speeds. At target dry weather wet well elevations, the pumps run between the minimum and maximum POR only at a pump speed of 75 to 85 percent.

When the storm pumps are operating and there is no wet weather capacity in the downstream sewer to the NWI, the control system should automatically operate the sanitary pumping system in recirculation mode, to minimize settling of grit and solids within the sanitary pump wet wells. (It is currently operated in manual.) Recirculating sanitary flow during wet weather events may be delaying the time it takes to empty the wet well and wasting energy. However, the cost/down time associated with unclogging pumps may outweigh the energy utilized to recirculate flow.

The maximum firm capacity from Sanitary PS is approximately 15 to 20 MGD. The minimum recommended flowrate for the Storm PS is approximately 65 to 75 MGD. The dead band between these two capacities significantly limits ease-of-operations for small and intermediate sized storm events based on current operating strategies.

11.2.13.3 Recommendations

The following actions are recommended to address issues identified with the sanitary pumps:

- Modify operating setpoints and test new operation. Testing would include the further development of proposed new operating procedures and setpoints, coordination with GLWA Oakwood CSO O&M staff

GLWA field Services O&M staff and execution on one or more storm events. Update O&M manual with the new operating procedures

- It is recommended that the manual operated bar racks be removed to prevent sewage backup into the storm pump intakes. See Screening Section 11.2.1 above for further discussion.

11.2.14 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Oakwood CSO facility, Table 11-24 and Table 11-25 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 11-24 and Table 11-25, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 11-24. Listing of Asset Condition Assessments for Oakwood CSO (CSO-OKW) Facility

^a The Oakwood – Pumping Station Building was not evaluated.				

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near

future. Based on the review of the Oakwood Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

11.3 Capital Planning for Oakwood CSO Facility

11.3.1 Summary of Capital Improvement Plan Projects

Table 11-26 provides a summary of the recommended CIP projects and associated capital costs for the Oakwood CSO facility based on the alternative evaluations conducted for this facility.

Table 11-26. Summary of Recommended Projects at Oakwood CSO Facility

Project No.	Alternative	Description	Total Project Cost
OKW-SCR-1	2	Remove Bar Racks	Capital Outlay
OKW-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 443,000
OKW-DIS-2	2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
OKW-DIS-3	1	Reline and Provide Side Access Manways	\$ 289,000
OKW-FD-1	2	Influent Junction Chamber Isolation Improvements	\$ 289,000
OKW-FD-2	2	Reservoir Flushing Valves Relocation and Sump Flushing	\$ 536,000
OKW-ELEC-1	2	Electrical Improvements	\$ 262,000
OKW-I&C-1	2	I&C Improvements	\$ 347,000
OKW-I&C-2	1	Control System Upgrade	\$ 1,003,000
OKW-SITE-1	2	Site Improvements	\$ 732,000
OKW-ARCH-1	2	Architectural Rehabilitation	\$ 880,000
OKW-SAFE-1	1	Safety Improvements	\$ 338,000
OKW-PUMP-1	2	Rehabilitate Storm Pumps	\$ 4,100,000

11.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 11-27. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 11-27. Capital Improvement Plan Projects for Oakwood CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
OKW-1 Disinfection System Improvements	\$ 1,424,000	2026 <i>Timing based on implementation of projects before NWI diversion to ensure reliable operation with increased flows.</i>	OKW-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 443,000
			OKW-DIS-2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
			OKW-DIS-3	Reline and Provide Side Access Manways	\$ 289,000
			OKW-FD-1	Influent Junction Chamber Isolation Improvements	\$ 289,000
			OKW-FD-2	Reservoir Flushing Valves Relocation and Sump Flushing	\$ 536,000
OKW-3 Facility-Wide Electrical and I&C Improvements	\$ 1,612,000	2029 <i>Timing based on asset condition</i>	OKW-ELEC-1	Electrical Improvements	\$ 262,000
			OKW-I&C-1	I&C Improvements	\$ 347,000
			OKW-I&C-2	Control System Upgrade	\$ 1,003,000
OKW-4 Site Improvements	\$ 732,000	2030 <i>Timing based on best judgement</i>	OKW-SITE-1	Site Improvements	\$ 732,000
OKW-5 Facility-Wide Safety and Architectural Improvements	\$ 1,218,000	2023 <i>Project should be initiated as soon as possible</i>	OKW-ARCH-1	Architectural Rehabilitation	\$ 880,000
			OKW-SAFE-1	Safety Improvements	\$ 338,000
OKW-6 Rehabilitate Storm Pumps	\$ 4,100,000	2022 <i>Timing based on condition</i>	OKW-PUMP-1	Rehabilitate Storm Pumps	\$ 4,100,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 11-28 and Table 11-29 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 11-28 indicates that OKW-DIS-1 project has 52 assets that have an average condition score of 1.15 and an average replacement date of 2041. However, this project should be completed before the NWI diversion to ensure reliable operation with increased flows and therefore, the project was proposed a scheduled construction completion date of 2026 instead of 2041.

Table 11-28. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
OKW-DIS-1	52	1.24	1.15	1.95	23	2041	\$ 1,819,300
OKW-DIS-3	2	2.14	1.00	3.21	15	2035	\$ 118,400
OKW-I&C-1	8	1.14	1.91	2.24	15	2031	\$ 145,600
OKW-I&C-2	1	2.29	1.57	4.08	12	2029	\$ 580,725

Table 11-29. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
OKW-DIS-1	1	1.29	5.00	4.50	10	2021	\$ 145,000
OKW-DIS-3	0	0.00	0.00	0.00	N/A	N/A	\$ -

11.3.3 20-Year Capital Outlay Plan

Table 11-30 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 11-30. 20-Year Capital Outlay Plan for Oakwood CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 671,213	\$ 20,010	\$ 30,000	\$ -	\$ 145,000	\$ -	\$ -	\$ 429,435	\$ -	\$ -	\$ 46,768	\$ -	\$ -

Notes:

Explanation of large capital outlays in first two years:

- Screening System: The screen spray water booster pump in the makeup air room was out of service at the time of the Condition Assessment. GLWA has repaired this asset since then.
- Retention System: Two reservoir fill valves (Nos. 3 and 5) in the West Basin (\$6,900 each) received a score of 5 because the valves may not open again if they are closed. One drain valve (DV-7; \$13,000) received a score of 5 because the valve body was removed from the pipeline.
- Disinfection System: One chemical feed pump (No. 6) received a score of 5 since the pump had been removed from the skid at the time of the Condition Assessment.
- Odor Control System: One carbon scrubber in the basin Odor Control Room received a score of 5 because the unit was not in service at the time of the Condition Assessment.
- HVAC System: Three exhaust fans (EF-5, EF-20, and EF-24) and four supply fans (SF-7 to 10) received a score of 5 since they have been out of service for some time. An ongoing HVAC project is addressing these units.

12. Puritan-Fenkell CSO Control Facility

12.1 General Facility Description and Future Capacity Considerations

12.1.1 General Facility Description

The Puritan-Fenkell CSO Facility is an RTB with 2.8 MG of storage and a treatment capacity of 845 cfs. It was constructed in 1996. The facility has not experienced the originally anticipated level of flows, in fact, the facility did not discharge from 2016-2018 and only a few times in 2019 and 2020. For this reason, Section 12.1.2 describes potential modifications to make this facility into a "Capture-Only" facility. A similar recommendation is made for Seven Mile CSO Facility.

The facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

12.1.2 Modifications to Make Puritan-Fenkell Facility into a Capture-Only Facility (PF-WWMP-1)

The WWMP recognized that "GLWA has developed a protocol to operate the Puritan-Fenkell and Seven Mile basins in capture-only mode (no treatment or discharge) for flows up to the 10-year 1-hour design storm. This finding provides a significant water quality benefit because the 1,114-acre service area can be captured, stored, and returned to the WRRF following a storm event preventing release of an estimated 700 million gallons of CSO each year."

Operating these two facilities in capture mode would allow for the cost avoidance of operating and maintaining the hypochlorite feed and storage systems and it would likely not require operations labor to be onsite during a storm event. Screening the influent flow is still recommended, particularly since the screens are already installed, to prevent large debris from entering the capture basin.

Wade Trim conducted a study ("Puritan-Fenkell and Seven Mile CSO Retention and Treatment Basins Basin Collection System and Hydraulic Analysis", dated August 29, 2019). This hydraulic study included an analysis "to evaluate the potential of operating the basins in capture-only mode as a possible operational protocol for the system. Capture basin operation was evaluated to understand the impacts on untreated overflow from the 17 Main Rouge River outfalls on the Detroit West Side system, flooding impacts of the utility tunnels within the two basins, and the risk of upstream basement flooding."

The findings of the study included:

- Limited (approximately 2 percent) increase in untreated overflow from the 17 Main Rouge River outfalls as a result of capture mode operation.
- Impact to the utility tunnels when operating in capture mode is expected for design storms between the 10-year, 24-hour and the 25-year, 24-hour storm at the Puritan-Fenkell basin. At the Seven Mile basin, design storms slightly smaller than the 10-year, 24-hour storm will begin to impact the utility tunnel.
- The evaluation of basement flooding risk shows the basins can be operated in capture mode for the 10-year, 24-hour storm without risk of basement flooding. However, during the 25-year, 24-hour storm significant basement flooding can be expected.

The report concluded that operating the basins in capture-only mode in their current configuration is not recommended due to the risk of basement flooding. The report indicated, however, that capture-only mode may be possible if high level emergency overflows are added to the basins to relieve the system during extreme events to protect basements from flooding.

To aid in the analysis of operating both Puritan-Fenkell and Seven Mile as capture-only basins, conceptual cost estimates have been generated under CS-299 for both facilities including capital improvements listed below. The Wade Trim hydraulic study provided some details regarding these issues, which are included in the description of the conceptual cost estimate; however, additional study and design will be needed.

- 1) Emergency overflow relief. The current weir wall is about 12 ft high at both facilities. A new weir wall about 20 ft high and associated structural modifications are needed at the effluent end of the basin to construct a taller weir wall (see Figure 12-1). The length of weir was not reported and should be included in the future study.
- 2) Utility tunnel flooding protection. Water-tight doors are recommended where there is access to the basin from the utility tunnel and at the influent end of the utility tunnel. The proposed doors can withstand 20-ft of static head.
- 3) Replace the existing effluent butterfly gates with flap gates. The Wade Trim report evaluated two different locations for these gates at each facility, which would prevent backflow into the facility (see Figure 12-2). Additional study should be performed to determine if these flap gates are still needed with the taller proposed weir wall.

Figure 12-1. Proposed Modification to Effluent Weir Wall for Emergency Overflow Relief

Figure 12-2. Potential Options for Flap Gate Retrofit – Puritan-Fenkell (from Wade Trim Report)

A preliminary life-cycle comparison is presented in Table 12-1. Alternative 1 represents the scenario where the facility continues to operate as an RTB. Alternative 2 represents a scenario where the facility operates in the complete capture mode. The intent of this comparison is to present the cost of the emergency overflow weirs and flap gates compared to the avoided costs associated with maintaining the disinfection system and flow meters for the flow-through treatment mode of operation. The following costs are used in this evaluation:

- The period of evaluation is assumed to be 50 years, which represents an approximate remaining life of the basin.
- For Alternative 1, the capital costs were obtained from the SRP replacement costs and include the chemical feed pumps, drives, piping, and storage tanks. It also includes the flow meters for the effluent and shunt channel. It is assumed for this analysis that all of these assets would be replaced twice during the period of evaluation.
- For Alternative 1, the O&M costs include those items that are currently needed, but would no longer be needed under a complete capture mode. These costs include Operations labor before and during storm events to make the facility ready for discharge, if necessary (assumed to be 8 storm events per year and 10 hours per storm event). Costs also include hypochlorite usage or degradation of the hypochlorite in one tank (4,000 gallons) every six months at a unit cost of \$0.90 per gallon.
- For Alternative 2, the total project cost for the modifications described for the emergency weirs and flap gates is provided in Volume 6 – Appendices, Appendix C, under PF-WWMP-1. The costs also include permitting and modeling to demonstrate and coordinate the modifications with Michigan EGLE.

As shown in Table 12-1, the Best Value Alternative is Alternative 2 – Convert to Complete Capture Basin. As such, it is recommended that this alternative be pursued through additional modeling to confirm water levels in the collection system during peak storm events and coordination with Michigan EGLE.

Table 12-1. Alternative Evaluation for Puritan-Fenkell Convert to Complete Capture Basin

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ 2,836,400	\$ 15,200	\$ 3,702,286	\$ 1,480,914	
	<i>Definition:</i>	Do nothing. Continue to operate as an RTB	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system; no new regulatory issues	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher level of operator attention during storm events. Must maintain hypochlorite storage and feed system.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Convert to Complete Capture Basin	Health and Safety	4	3.72	\$ 2,600,000	\$ -	\$ 2,600,000	\$ 699,552	Best Value Alternative
	<i>Definition:</i>	Convert to Complete Capture Basin	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less operator attention during storm events. No O&M for hypochlorite system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires regulatory approval; Modeling confirmation of acceptability	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

12.2 Facility Assessment

12.2.1 Screening

12.2.1.1 Description of Existing System

The Puritan-Fenkell CSO Facility has three mechanically cleaned bar screens that were installed in 1996. Influent wastewater from a 12-ft diameter influent sewer enters the headworks area of the facility and flows through the screens into the basin compartments. Material collected by the screens is mechanically raked from the bar screens and deposited into a dumpster to be hauled to the landfill.

Table 12-2 provides an overview of the existing screening system at Puritan-Fenkell CSO facility.

Table 12-2. Overview of Existing Screening System at Puritan-Fenkell CSO Facility

Parameter	Value
Treatment Capacity (cfs)	845
No. of Screens	3
Manufacturer	Jones and Attwood
Screen Type	Catenary Bar Screen
Opening Size	0.5-in. spacing
Depth or Length / Width	29 ft 1 in / 9 ft 4 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

12.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide screening retention plate along entire conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt.
- Replace conveyor belt as corrugated sidewall part of belt has torn off from large sections of the belt.
- Need for automatic start for screens and belt.
- Change location of screen controls.
- Prevent screens from swaying during operation. During higher flow events, the screens reportedly sway to some degree. The operators believe this is caused by the returning rake getting tossed by the rapid flow of water and affecting the rest of the screen. They noted that the Conner Creek screens (which is a similar screen but does not sway) has chain guide returns that extend closer to the floor of the channel. This issue was added to the scope of the OEM evaluation; however, the OEM was unable to see the swaying because flow did not occur during the site visit. If this issue causes problems in the future, it should be video-taped to document the issue.

- Address worn teeth on screen rakes. The OEM condition assessment assessed the condition of the screen components. They noted some rakes had a significant amount of corrosion, but they did not indicate the need for replacement.
- Provide improved means to install stop logs in influent area. GLWA requested a means for installing the stop logs with a permanent type of system. The channels for the stop logs for each screen are very close to Headworks building wall (see drawing in Figure 12-3). The reach of the overhead crane is unable to lower the logs directly into place.

Figure 12-3. Location of Stop Log Guides at Puritan-Fenkell Headworks

It should be noted that a sluice gate is proposed upstream of the sanitary pumps (and downstream of the screens) in the Flushing and Dewatering section (Section 12.2.4). This will allow isolation of the sanitary wet well from the rest of the facility.

It should also be noted that one of the screen channels has the influent channel running through the bottom of the opening. It is not clear how the existing stop log were intended to stop flow, given the 2 ft by 2 ft channel running through the bottom of the channel floor. Furthermore, all of the stop logs would need to be installed (and the channel properly isolated) to isolate the screen channel during a wet weather event because there is no stop log on the downstream side of the screen.

Jacobs investigated installing sluice gates. Based on the hydraulic profile, gates with 18 ft height and 10 ft width would be needed. This size would require two leaf gates; however, there is not enough room for two leaves. The gates could be shorter height if designed for a smaller storm event. Then, one gate could be used. The proposed gates would normally reside in the “up” position, out of the water channel and be lowered using an actuator when needed.

Given the infrequent need for installing the stop logs and the redundancy of the screens, it is suggested that a temporary means of installing the stop logs should be utilized when screen replacement or major rehabilitation is required.

12.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Screening Improvements (Project PF-SCR-1). Due to the relatively small nature of some of the screening-related issues identified as improvements, all of the identified screening improvements are proposed to be in one project – Screening Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Screening Improvements** including,

- Screening retention plate along entire conveyor
- New conveyor belt
- Provide programming modifications for automatic start for screens and belt
- Relocate screen controls.

Each of the screening related improvements listed above is described further below:

Screening Retention Plate Along Entire Conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt. A cost for a screening retention plate (similar to screening retention plate at Conner Creek) is included in the capital cost estimate.

New conveyor belt. A new conveyor belt is recommended, as opposed to rehabilitating the existing belt. The cost estimate includes a new belt.

Provide programming modifications for automatic start for screens and belt. Programming modifications to provide automatic start of the screen and conveyor belt based on influent water level (for the screens) and start of screens (for the conveyor belt).

Relocate screen controls. The screen control box is located on the wall next to the conveyor. During screening operation, access to this location requires the operator to stand by a discharging screen. Although the screening plate may reduce splatter, it may still occur.

The alternative evaluation is presented in Table 12-3. The sources of costs used in this evaluation are listed below:

- Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.
- The difference in O&M costs between the two alternatives will be negligible.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$66,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Screening Improvements is the recommended alternative.**

Table 12-3. Alternative Evaluation for Screen Improvements (Project PF-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Operator needs to be present to start screen.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Screening Improvements	Health and Safety	4	3.50	\$ 230,000	\$ -	\$ 230,000	\$ 65,714	Not Applicable
	<i>Definition:</i>	Provide screening retention plate, new conveyor belt, automatic screen and conveyor	Water Quality & Compliance	3						
	<i>Adv.:</i>	Operator does not need to be present to start screen, cleaner/safer operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.2 Disinfection

12.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, four gear pumps, two induction mixers, and two in basin mixers. There are three screens discharging into a common influent channel to Basins 1 or 2. There are two induction mixers located upstream of the bar screens and two submersible mixers with chemical feed, one in each basin. The sodium hypochlorite pumps discharge to a common header with a flow meter that splits to the two induction mixers, Basin 1 mixer, and Basin 2 mixer. Although there are flow indicators after the split to the two induction mixers, flow splitting is not metered and there does not appear to be any basis to achieve equal flow splitting. Currently, operations primarily feed to the basin mixers and if they suspect a strong chlorine demand in the influent, they will also feed to the two induction mixers in the influent.

Table 12-4 provides an overview of the existing disinfection system at Puritan-Fenkell CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 12-4. Overview of Existing Disinfection System at Puritan-Fenkell CSO Facility

Parameter	Value
Treatment Capacity (cfs)	845
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L Cl ₂)	10 @ 845 cfs

Number/Type	2 / Submersible mixers
Model Number / hp / Manufacturer	4600-Series / 20 / Flygt

12.2.2.2 Identified Needs and Issues

The needs and issues identified for Puritan-Fenkell were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are summarized as follows:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Puritan-Fenkell chemical feed system has the following issues:
 - No flow metering to individual feed points to control the feed split
 - Consider need to enlarge area to accommodate alternative type of pumps.
 - Evaluate possibility of gravity feed from the chemical tanks with a meter and control valve. Jacobs evaluated the possibility of this type of feed system. The effluent weir from the CSO basins

controls the hydraulic grade line at the influent induction mixers to above elevation 124 once the basin is filled. The bottom of the sodium hypochlorite tanks are at approximately elevation 142 and the maximum liquid depth is approximately 8 ft. Thus, there is approximately 18 ft of static head available with the tanks empty and 26 ft with the tanks full. This corresponds to 7.8 pounds per square in. gauge (psig) empty to 11.2 psig full available head. The induction mixers require back pressure valves to prevent siphoning chemical. Evoqua recommends a setting of 15 psig. Therefore, the available static head is inadequate for gravity feed before even accounting for friction loss and flow control valve loss. Thus, continued pumping as the means of chemical delivery is recommended.

The first two issues are addressed in Replace Chemical Feed System (Project PF-DIS-1).

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project PF-DIS-2) below.

12.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project PF-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, PF-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.

It should be noted that hose pumps will be larger than the existing gear pumps and the need to enlarge the pump area was considered to verify the feasibility of this alternative. The Bredel 65 pumps have a base of 29 in. by 28 in. The pump and motor cantilever beyond the base plate and pad and have maximum dimensions of 42 in. by 46 in. The existing pump area is about 5 ft wide and 18 ft long excluding the doors. If one pump were provided per feed point using the pump distribution alternative, then there would be 5 pumps including a spare. This would fully consume the approximate 18 foot length with no space between the pumps for maintenance or access. Thus, the pump area would need to be expanded for this alternative. The separate pump containment could be eliminated, and the pumps located on pads at a sufficient height for spill protection. This is reflected in the cost estimate for this alternative.

- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 12-5. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.

- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on manufacturer pump rebuilds at a cost of \$7,500 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 12-5 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Note that this project would not be recommended if the basin is converted to complete capture.

Table 12-5. Alternative Evaluation for Replace Chemical Feed System (Project PF-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System in-kind	Health and Safety	3	2.08	\$ 340,000	\$ 7,500	\$ 498,172	\$ 239,123	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 687,000	\$ 4,410	\$ 780,005	\$ 216,668	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 383,000	\$ 3,000	\$ 446,269	\$ 123,964	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project PF-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose using an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The storm pump flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on storm pump flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows. The sampling location would be near the influent end of the basin and near the bottom portion of the basin (to be able to measure TRC concentrations before the effluent sample point).

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 12-6. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Note that this project would not be recommended if the basin is converted to complete capture.

Table 12-6. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project PF-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Replace existing chemical feed control system utilizing current level of controls and	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Install Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common of CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

12.2.3 Odor Control

12.2.3.1 Description of Existing System

The Puritan-Fenkell odor control system consists of two separate odor control systems. One system treats foul air from the Headworks and pump station wet well area and the other treats foul air from the basins. Each system includes a scrubber tower, recirculation pump, caustic feed system, hypochlorite feed system, and an odor control fan. The original system was designed to feed sodium hydroxide and sodium hypochlorite; however, the sodium hydroxide has not been used for some time. The scrubber tower contains 5.5 ft of plastic media with a chemical spray section located above the media.

The system was installed in 1996. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past 3 years.

12.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack.

Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous. Prior to implementing either one of these options, GLWA could sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water.

12.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs."

12.2.4 Flushing and Dewatering

12.2.4.1 Description of Existing System

Dewatering System: Water from the basin can be dewatered by gravity after a storm event. There are also three dewatering pumps used to dewater the basin. Dewatered flow is conveyed to the NWI.

Flushing System: There are a total of 16 tipping buckets on the side walls of both basin compartments and the influent channels. City water is used to fill the tipping buckets.

Table 12-7 provides an overview of the existing flushing and dewatering system at Puritan-Fenkell CSO facility.

Table 12-7. Overview of Existing Flushing and Dewatering System at Puritan-Fenkell CSO Facility

Parameter	Value
Total Basin Volume (MG)	2.8
Headworks and basin Dewatering and Flushing System	- There are three 3,200-4,500 gpm dewatering pumps 7 tipping buckets for each basin (14 total) 2 tipping buckets in influent distribution channel

12.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- There is no way to achieve positive isolation between the dry weather and wet weather wet wells
- The bearing assemblies for the tipping buckets are inaccessible for periodic inspection
- A number of actuators on the flushing lines have been removed and not replaced
- The dewatering force main from the CSO facility to the NWI is inaccessible but may require future inspection and cleaning
- O&M staff noted that a water spray system is needed near the influent and dewatering pumps to clean the platform and grating around the area

12.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Isolation of Sanitary and Dewatering Wet Well (Project PF-FD-1). The Puritan-Fenkell CSO facility continuously functions as a lift station for dry weather flows using two dry weather submersible pumps. These pumps and associated wet well are fed through a low-flow trough in the influent channel and they are adjacent to the basin dewatering pumps and their associated wet well. Currently, there is no secure way to achieve positive isolation between the dry weather and wet weather wet wells and GLWA O&M staff requested this be provided.

There are two alternatives for this project:

- Alternative 1: Do Nothing.**
- Alternative 2: Wet Well Improvements.** In 2013, Metco prepared a basis of design report, with a figure and cost estimate to provide a new 30-in. by 30-in. stainless steel gate on the influent to the dry weather wet well. See Volume 6 – Appendices, Appendix B, for figures (Figure PF-FD-1-ALT-2) of the proposed layout.

O&M staff noted that a water spray system is needed near the influent and dewatering pumps to clean the platform and grating around the area. An NPW line running from the Control Building to the hypochlorite storage room could be tapped and routed to the catwalk area located below the

Headworks floor. Multiple water cannons could be arranged to adequately clean the area. See Volume 6 – Appendices, Appendix B, for figures (Figure PF-FD-1-ALT-2) for a conceptual layout.

The alternative evaluation for these alternatives is presented in Table 12-8. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.5 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M and component performance provided by the added wet well isolation and spray system. The NPV/Benefit cost for Alternative 2 is \$24,000, which is a relatively low cost compared to other projects recommended in this assessment. As such, **Alternative 2 – Wet Well Improvements is the recommended alternative.**

Access to Tipping Buckets (Project PF-FD-2). O&M staff noted that the bearing assemblies for the tipping buckets are inaccessible; however, they require periodic inspection. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Access to Tipping Buckets for Maintenance.** This alternative consists of constructing manhole openings above each adjoining set of rotating groups. A total of 19 manhole openings are required, including one over each bearing assembly on the end tipping buckets.

The bearing assemblies are located in an unpaved area atop of the basins. Installation requires excavating to the top of the existing roof slab. A 24-in. opening will be cored through the roof, and manhole grade rings set/doweled over the opening and extended to 6 in. above the existing ground surface to prevent runoff intrusion. A standard 24-in. manhole ring and lid will be set and bolted to the grade rings, and the excavation backfilled around the new access point. Final restoration will include lawn seeding.

The costs include extending a 0.5-in. metal grease tube and grease gun fitting from each bearing assembly to within 6 in. of the surface at the nearest new manhole opening (two zerks per manhole, one each at the end tipping buckets). After consultation with the tipping bucket gate manufacturer, regular greasing of the bearings is not required for the model of tipping buckets installed at the Puritan-Fenkell CSO Facility. GLWA may elect to install the access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly. Figures PF-FD-2-ALT-2, included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

Finally, a number of actuators have been removed and not replaced. The replacement of these actuators has been included in the cost estimate.

The alternative evaluation for these alternatives is presented in Table 12-9. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and increased ease of O&M provided by the improved access to the tipping bucket bearings. The NPV/Benefit cost for Alternative 2 is \$27,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 – Provide Access to Tipping Buckets for Maintenance is the recommended alternative.**

Table 12-8. Alternative Evaluation for Wet Well Improvements (Project PF-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not applicable

	<i>Definition:</i>	Construct 19 manhole openings, including one over each bearing assembly on the end tipping buckets	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Dewatering Force Main (Project PF-FD-3). GLWA noted that the dewatering force main from the CSO facility to the NWI is inaccessible but will require future inspection and cleaning. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Access to Dewatering Force Main for Inspection and Cleaning.** This alternative consists of the installation of cleanouts at the following locations: 1) at the end of the force main, southwest of the siphon head chamber in Manhole No. 1 for cleaning of the force main, 2) northeast of the Manhole No. 1 before the inverted siphon, and 3) on the east side of the Rouge River, just before Manhole No. 2. (See Figure PF-FD-3-ALT-2 included in Volume 6 – Appendices, Appendix B.)

The alternative evaluation for these alternatives is presented in Table 12-10. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.6 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M and improved component performance provided by the ability to access the force main. The NPV/Benefit cost for Alternative 2 is \$27,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Dewatering Force Main is the recommended alternative.**

Table 12-10. Alternative Evaluation for Access to Dewatering Force Main (Project PF-FD-3)

2	<i>Alt. Name:</i>	Access to Dewatering Force Main for Inspection and Cleaning	Health and Safety	3	3.32	\$ 90,000	\$ -	\$ 90,000	\$ 27,136	Not applicable
	<i>Definition:</i>	Install cleanouts at a number of locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access to the dewatering forcemain from the CSO facility to the NWI for future inspection	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.5 HVAC

12.2.5.1 Description of Existing System

The Puritan-Fenkell CSO facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard. The facility also includes the retention basins. Table 12-11 provides summary of the major equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, emergency shower/eye wash, regular shower, and drinking fountain. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 12.2.10.

Table 12-11. Major HVAC Equipment at Puritan-Fenkell CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-2	Heating and Ventilating Unit	11,100 CFM
	EF-5	Exhaust Fan	10,000 CFM
Basin	SF-1 and 2	2 × Supply Fans (Basin Ventilation)	97,000 CFM
	SF-3	Supply Fan (Shunt Valve Chamber)	2,300 CFM
	SF-4	Supply Fan (Effluent Valve Chamber)	2,300 CFM
	EF-7	Exhaust Fan (Shunt Channel Valve Chamber)	400 CFM
	EF-8	Exhaust Fan (Effluent Valve Chamber)	400 CFM
	UH-1	Unit Heater (Shunt Channel Valve Chamber)	400 CFM 17.0 MBH
	UH-2	Unit Heater (Effluent Valve Chamber)	400 CFM 17.0 MBH
Odor Control Room	HVU-1	Heating Ventilating Unit	4,700 CFM
	EF-5	Exhaust Fan	4,700 CFM
Electrical Room	PACU-1	Heating Ventilating Unit	2,200 CFM

Table 12-12 provides a summary of the basis of design performance criteria for HVAC systems at Puritan-Fenkell and Table 12-13 provides the outdoor Basis of Design conditions.

Table 12-12. Puritan-Fenkell Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Retention Basin	Class I, Group D, Div 1	N/A	N/A	10 ACH
Headworks and Pump Room	Class I, Group D, Div 1	60	N/A	12 ACH
Odor Control Room	Unclassified for areas greater than 3 ft from odor control vessel. Class I, Group D, Div 2 for areas closer than 3 ft.	70	N/A	10 ACH
Electrical Room, Work Room, Office, Toilet, Etc.	Unclassified	70	78	2 cfm/ft ²
Basement (Magnetic Meter Room)	Unclassified	70	N/A	6 ACH
NaOCl Storage Room	Unclassified	60	N/A	6 ACH

Outdoor Design Temperature		
Winter (Dry Bulb F)	Summer (Dry Bulb F)	Summer (Wet Bulb F)
3	91	73

12.2.5.2 Identified Needs and Issues

During the Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- PACU-1 requires replacement.
- HVU-1 in Odor Control Room requires replacement.
- Supply and exhaust fans in Shunt Channel and Effluent Channel require replacement.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- PACU-1 requires constant maintenance to keep running: GLWA's HVAC contractor noted that PACU-1 has had a multitude of problems including damper problems, actuator problems, refrigerant leaks and wiring issues.
- HVU-1 locks out at least once a week.
- HVU-3 is very difficult to service due to location.

During site investigations (June 2020), the following observations were noted:

- PACU-1 was down for repair and GLWA's HVAC contractor staff were working on it on the day the site investigation took place.
- The exhaust fan was off in the Headworks Area

- Improvements are needed for code compliance in the Odor Control and Headworks Areas
- SF-1 and SF-2 were functional but had corroded bases

12.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project PF-HVAC-1). Due to the numerous HVAC-related assets that require replacement in-kind and the additional need to provide monitoring for code compliance in the Odor Control Room and Headworks, all of the identified HVAC improvements are proposed to be in one capital improvement project – HVAC Improvements. As such, there is only one alternative for this project, which includes:

- PACU-1 Replacement
- Improvements to Enhance Safety in Odor Control Area
- Improvements to Enhance Safety in Headworks Area
- HVU-1 and 2 Replacement
- HVU-3 Replacement (with improved access)
- SF-1 and SF-2 Replacement
- Exhaust Fan Replacement
- Removal of Shunt Channel and Effluent Channel HVAC Equipment

Each of the HVAC-related improvements listed above are described further below:

PACU-1 Replacement. Given the age of PACU-1 (24 years), the lengthy history of various issues, and the fact that the unit was undergoing repair the day of site walkthrough, replacement of PACU-1 with a more efficient modern unit and controls is recommended.

Improvements to Enhance Safety in Odor Control Area. The Odor Control area is classified as a Class I, Division 2 space under NFPA 820 if it is not continuously ventilated at a rate of 6 ACH. The space does not meet the 6 ACH ventilation requirement and does not currently have electrical equipment rated for a Class I, Div 2 environment. HVU-1 is designed to provide 10 ACH of ventilation air in cooling mode but was sized to provide only 2 ACH of outside air in heating mode. Additionally, EF-2 is only designed to operate in cooling mode at 10 ACH. NFPA 820 requires both supply and exhaust fans to operate continuously to declassify odor control areas.

Given the age of HVU-1 and EF-2 and the problems HVU-1 is exhibiting, Jacobs recommends replacement of both units. HVU-1 and EF-2 could be replaced with units with two-speed fans or VFDs to provide 6 ACH continuously during ventilation and heating and 10 ACH in cooling mode.

Regardless of whether the space is unclassified by providing 6 ACH of outside air, NFPA 820 requires the installation of combustible gas detection in the Odor Control area with audible and visible alarms at all entrances to the Odor Control area and within the space.

If ventilation is used to declassify the space as described above, ventilation flow monitoring of both the supply and exhaust fan is required with visible and audible alarms of a low or no flow condition required at entrances and within the space.

Improvements to Enhance Safety in Headworks Area. HVU-2 serves the Headworks Area, which is classified as a Class I, Division 1 space per the design drawings. Given its age, and general condition, it should be replaced. Because the electrical equipment in the space is rated for a Class I, Division 1

environment continuous ventilation and ventilation flow monitoring are not required. NFPA 820 does, however, require combustible gas detection with visible and audible alarms at the entrances to the Headworks area and inside the space, which the Headworks area currently does not have. Jacobs recommends making this change to comply with NFPA 820.

HVU-3 Replacement (relocated with improved access). HVU-3 is currently mounted high in the Metering Room in the basement making access for maintenance very difficult (Figure 12-4). Placing HVU-3 lower in the space would make access to the magnetic meter and associated piping very difficult, which is likely the reason the decision to mount the unit high in the space was made. Jacobs recommends replacing HVU-3 with a unit mounted on a concrete pad on the North side of the building when HVU-3 requires replacement. There is an existing opening for the Meter Room supply air duct, which could be utilized by the outdoor unit. This approach would allow ample space for maintenance and would make removal much easier. Currently, HVU-3 will need to be removed in sections when replacement is necessary.

Figure 12-4. HVU-3 Located in Difficult to Access Location Located in Inaccessible Area

SF-1 and SF-2 Replacement. SF-1 and 2 are functional despite having corroded bases (Figure 12-5). These units will require replacement in the near future.

Figure 12-5. Corroded Supply Fan Bases – View from Above (left) and View from Below (right)

Exhaust Fan Replacement. There are five relatively small exhaust fans that are original to the facility and should be included in the replacement project.

Removal of Shunt Channel and Effluent Channel HVAC Equipment. The unit heater, supply and exhaust fans in the Shunt Channel and Effluent Channel are not used and are inoperable. These units could be retired. Portable ventilation could be utilized, if necessary, when operators need to enter these areas.

The alternative evaluation is presented in Table 12-14. **The capital cost for Alternative 1, which is the recommended alternative,** is included in Volume 6 – Appendices, Appendix C under this project title.

Table 12-14. Alternative Evaluation for HVAC Improvements (Project PF-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	3	3.00	\$ 810,000	\$ -	\$ 810,000	\$ 270,000	Best Value Alternative
	<i>Definition:</i>	Facility-wide HVAC Improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, less emergency maintenance, improved asset reliability.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.6 Electrical

12.2.6.1 Description of Existing System

The Puritan-Fenkell electrical system consists of one DTE utility feed from a 750 kVA, 480/277 V, 3-Phase outdoor transformer (secondary metering) and diesel generator feed from a 400 kW, 480/277 V, 3-Phase stationary generator. The feeds are connected to a 1,200 A MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP has breakers that feed MCCs and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 12-15 provides a summary of the major electrical equipment for this facility.

Table 12-15. Major Electrical Equipment at Puritan-Fenkell

Location	Major Electrical Equipment	Description
Electrical Room	Main distribution panel with ATS	1,200 A, 480/277 V, 3-Phase
Courtyard	Generator (Diesel)	400 kW, 480/277 V, 3-Phase
Electrical Room	MCC-1	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	600 A, 480/277 V, 3-Phase

12.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the following section.

12.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project PF-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure PF-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Wet Well Chamber Area – Add LED lighting fixtures within the area to address the required foot-candles and code requirements.
 - Effluent channel – Add interior LED ceiling and wall mounted lighting fixtures within the area to address the required foot-candles and code requirements.
 - Basin – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the Basins. Lighting to meet the required foot-candles and codes for the area.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including receptacles every 100 ft on the backside exterior of the facility at ground level.

The alternative evaluation is presented in Table 12-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$59,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 12-16. Alternative Evaluation for Electrical Improvements (Project PF-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe due to poorer lighting at night	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 205,000	\$ -	\$ 205,000	\$ 58,571	Not applicable
	<i>Definition:</i>	Add additional lighting in wet well chamber area, effluent channel, and basins. Provide exterior power receptacles.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.7 I&C

12.2.7.1 Description of Existing System

Control System: The original Allen Bradley control system was installed in 1996 under PC-697. Since then, several modifications to the original system have taken place. These upgrades provided the ability to locally and remotely monitor the operations of the facility and the overall collection system, including from the SCC. The control system and workstation software are Allen Bradley PLC-5 redundant PLCs with Rockwell RSView software. The existing hardwired backup control panel and other miscellaneous PLCs and subsystems were also incorporated into the overall control system. The current PLC-5 control system, workstations and backup panels are obsolete, and do not meet GLWA SCADA Governance standards, which stipulate that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a backup radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 12-17 summarizes the level sensors and flow meters at the Puritan-Fenkell CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 12-17. Summary of Flow Meters and Level Sensors at Puritan-Fenkell CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent (Storm sewer)	1	Transit-Time (AccuSonic)
Shunt Channel	1	Transit-Time (AccuSonic)
Effluent Overflow Weir	2	Ultrasonic ^a
Basin Dewatering	1	Magnetic
CSO Level Sensors		
Influent (Storm Sewer)	1	Ultrasonic
Shunt Channel	1	Ultrasonic
Screening Area (Upstream and downstream of bar racks)	2	Ultrasonic
Basins	2	Ultrasonic
Wet Well	1	Ultrasonic

Effluent	1	Ultrasonic
River	1	Ultrasonic
Chemical System Flow Meters		
Process Water	1	Magnetic
Chemical Feed	1	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Pressure

^a Ultrasonic level sensor readings are used to measure height of water to allow calculation of effluent flow rate.

12.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system

12.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project PF-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: I&C Improvements** including,

- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 12-18. The sources of costs used in this evaluation are listed below:

- The O&M costs for Alternative 2 include estimated annual maintenance costs for the additional instrumentation provided.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – I&C Improvements, has a total benefit score about 0.3 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M provided by the various I&C improvements. The NPV/Benefit cost for Alternative 2 is \$53,000, which is a relatively lost cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 12-18. Alternative Evaluation for I&C Improvements (Project PF-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 70,000	\$ 5,000	\$ 175,448	\$ 52,899	Not applicable
	<i>Definition:</i>	Install tank level indication and process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Control System Upgrade (Project PF-I&C-2). The current facility's PLC control system, network, workstations and control system backup panels are obsolete and should be replaced in the near future. The control system does not meet GLWA SCADA Governance standards, which require that all CSO facilities use Ovation workstations with new high-performance graphics. GLWA's standards for local CSO facility's control systems can be either the latest Allen Bradley PLC system with Ovation workstations or a complete Ovation system. This approach is being used on an ongoing project at Leib, Seven Mile, and St. Aubin.

Because of the approach used on the ongoing project, there is only one overall control system alternative considered. The project should include decommissioning and removal of the original hardwired backup local control panels. These local panels are no longer required with today's redundant control system processors and local Operator Interface Terminal (OIT) as local backup to the facility's workstations.

Table 12-19 provides the summary of the **Control System Upgrade, which is the recommended alternative**. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Consideration should be given to replacing various field instruments during this project; however, these are not included in the capital costs.

Table 12-19. Alternative Evaluation for Control System Upgrade (Project PF-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 2,323,000	\$ -	\$ 2,323,000	\$ 774,333	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.8 Site

12.2.8.1 Description of Existing Site

Access to the site is off of Five Mile Road through a 25-ft wide swing gate. Site security is provided by a perimeter fence comprised of an 8-ft chain-link fence. The parking lot consists of 4-in. thick asphalt pavement with 8-in. gravel base. Sidewalks are 5 ft wide and consist of 4 in. of concrete with a 4-in. sand base. Site utilities include watermain, gas, sanitary and electric.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

12.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- Removal and installation of effluent stop logs is difficult.
- Rain gutters and downspouts are not installed, causing roof runoff to pond around the sidewalk, creating a safety issue for personnel accessing the building.
- Entrance Gate. The existing entrance security gate at the site is a 25-ft wide swing gate. This gate has been experiencing recurring maintenance issues recently and has reached the end of its useful service life. The gate should be replaced with a rolling gate.
- Repair cracks in asphalt parking lot surface.

The following issues were addressed under "*GLWA-CON-1902040 Site Improvements at P-F Detention Facility and Leib Screening and Disinfection Facility*" Contract and are not included in the capital improvement projects for CS-299.

- Extend Security Fence. The existing security fencing only extends around three sides of the Control Headworks Building and Basin. The river side of the site is not fenced.
- Address Drainage on Basin. The overburden cover on top of the basin roof is poorly drained and typically remains saturated for several days following a rain event. Service trucks with equipment have trouble navigating the basin roof while the soil is saturated.

12.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Stop Log Removal System for Effluent Gates (Project PF-Site-1). Removal and installation of stop logs is difficult. There are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

- 2) **Alternative 2: Stop Log Removal System for Effluent Gates.** A davit arm crane is recommended at the three hatch openings of the effluent gates and stop logs to assist in removal of hatch covers, the installation and removal of stop logs and other equipment from the effluent butterfly gate vault. A small area in the vicinity is recommended to be paved with concrete for temporary storage of stop logs.

Additionally, construction of a service road would assist access to the effluent gate vault site. Because the Puritan-Fenkell facility is located in a City park, the appearance of the service drive must blend in with the grass covered surroundings. It is recommended that the installed service road consist of an engineered fill base that will support a grass paver surface that will eventually support vegetation growth to better blend in with the natural surroundings, while giving vehicles access to the effluent gates. The service drive will extend from the existing Eliza Howell office parking lot and will be about 16 ft wide and approximately 265 ft long. Since this is in City park, it will likely require an easement. See Figure PF-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the conceptual layout.

The alternative evaluation is presented in Table 12-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$75,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Stop Log Removal System for Effluent Gates, is the recommended alternative.**

Table 12-20. Alternative Evaluation for Stop Log Removal System for Effluent Gates (Project PF-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Removal and installation of stop logs is difficult.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Stop Logs Removal System for Effluent Gates	Health and Safety	3	3.22	\$ 240,000	\$ -	\$ 240,000	\$ 74,611	Not applicable
	<i>Definition:</i>	A davit arm crane is recommended at the three hatch openings of the effluent gates and stop logs to assist in removal of hatch covers, the installation and removal of stop logs and other equipment from the effluent butterfly gate vault.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Ease of removal and installation of stop logs.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

General Site Improvements (Project PF-SITE-2). The roof on the Puritan-Fenkell Control and Headworks Buildings was recently replaced. However, rain gutters and downspouts were not installed. Roof runoff currently runs to the front of the Control Building and drops to grade where it tends to pond around the sidewalk, creating icy conditions during the winter and a safety issue for personnel accessing the building.

The Courtyard in the Headworks area has an open roof and is exposed to rain and snow falling on its floor surface. There are scuppers in the base of the south wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface.

This project also includes replacement of the entrance gate and restoration of the pavement.

There are two alternatives to address these issues:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: General Site Improvements:** It is recommended that a rain gutter and downspouts be added to the Control and Headworks Buildings to capture roof runoff and funnel it away from the building at grade. The Courtyard in the Headworks area has an open roof and is exposed to rain and snow falling on its floor surface. There are scuppers in the base of the south wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface. To alleviate the water ponding on the Courtyard floor, it is recommended that holes be cored through the courtyard floor to the basin below. Recessed area drains can be installed in the cored holes to funnel floor drainage to the basin.

This alternative also includes replacement of the entrance gate and restoration of the pavement.

The alternative evaluation is presented in Table 12-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$34,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – General Site Improvements, is the recommended alternative.**

Table 12-21. Alternative Evaluation for General Site Improvements (Project PF-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.62	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety concern related to ponding water and security issue with non-functioning gate	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	General site Improvements	Health and Safety	4	3.28	\$ 112,000	\$ -	\$ 112,000	\$ 34,112	Not applicable
	<i>Definition:</i>	Install rain gutter and downspouts; repair pavement	Water Quality & Compliance	3						
	<i>Adv.:</i>	Safety concern with ponding is eliminated	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.9 Architectural

12.2.9.1 Description of Existing Facilities

The Puritan-Fenkell CSO facility consists of chemical room, utility support (electrical), control room, odor control room, screen room, miscellaneous other rooms and a courtyard. The facility also includes retention basins.

12.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the ongoing Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff raised the following issues:

- It was identified that the existing basin access is through a 4 ft by 6 ft hatch with temporary wooden stairs and these stairs are not code-compliant.
- There is no access to the Headworks area and the Courtyard during a power outage.

These two issues are being addressed in an ongoing project under a JOC.

12.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (PF-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints

- Remove and replace isolation/ cove joint sealant and around building perimeter
- Remove and replace cracked façade limestone panels
- Replace damaged/stained/missing acoustic ceiling tiles in Control Building
- Address door hardware issues
- Clean, prepare surface and coat stained CMU walls in the Headworks

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure PF-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 12-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 12-22. Alternative Evaluation for Architectural Rehabilitation (Project PF-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 351,000	\$ -	\$ 351,000	\$ 113,226	Not applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.10 Safety

12.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

12.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 12-23. The capital improvement project to address these issues is included in the table.

Table 12-23. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Odor Control Room	No tempering valve on eyewash/shower	Provide tempering valve	Safety Improvements (Project PF-SAFE-1)
Chemical Room	Emergency eyewash/shower outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project PF-SAFE-1)
Chemical Room	Emergency eyewash/shower 0943390 outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project PF-SAFE-1)
Basement stairwell	No illuminated exit signs	Add exit signs	Exit Sign Improvements ^a
Headworks	Illuminated exit signs not working	Replace exit signs	Exit Sign Improvements ^a
Utility tunnel	Illuminated exit signs not present	Add exit signs	Exit Sign Improvements ^a
Utility Tunnel Access	Illuminated exit signs are out. Exit signs missing in locations.	Add or replace exit signs.	Exit Sign Improvements ^a
Utility Tunnel	Ladder at end of tunnel has an exit sign but hatch is locked.	Add placard to fixed ladder "Not An Exit." Replace existing exit sign with directional exit sign away from ladder access.	Exit Sign Improvements ^a
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project PF-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

12.2.10.3 Description and Evaluation of Needs and Issues

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project PF-SAFE-1). This project should address the safety issues identified above. These issues include:

- Provide tempering valve on eyewash/shower in the Odor Control Room
- Add eyewash/shower outside containment in the Chemical Room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 12-24 shows the one alternative.

Table 12-24. Alternative Evaluation for Safety Improvements (Project PF-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 126,000	\$ -	\$ 126,000	\$ 42,000	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Puritan-Fenkell CSO Facility.

12.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Puritan-Fenkell CSO facility, Table 12-25 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 12-25, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 12-25. Listing of Asset Condition Assessments for Puritan-Fenkell Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Three inactive pumps are listed in WAM - Basin 1 Sample Pump, Basin 2 Sample Pump, and Shunt Channel Sample Pump. These pumps are being considered for removal from WAM.

^d The Shunt Sampler 1 is listed in WAM. This sampler is being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Puritan-Fenkell Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

12.3 Capital Planning for Puritan-Fenkell CSO Facility

12.3.1 Summary of Capital Improvement Plan Projects

Table 12-26 provides a summary of the recommended CIP projects and associated capital costs for the Puritan-Fenkell CSO facility based on the alternative evaluations conducted for this facility.

Table 12-26. Summary of Recommended Projects at Puritan-Fenkell CSO Facility

Project No.	Alternative	Description	Total Project Cost
PF-WWMP-1	2	Convert to Complete Capture Basin	\$ 2,600,000
PF-SCR-1	2	Screening Improvements	\$ 230,000
PF-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 383,000
PF-DIS-2	2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
PF-FD-1	2	Wet Well Improvements	\$ 79,000
PF-FD-2	2	Provide Access to Tipping Buckets for Maintenance	\$ 95,000
PF-FD-3	2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
PF-HVAC-1	1	HVAC Improvements	\$ 810,000
PF-ELEC-1	2	Electrical Improvements	\$ 205,000
PF-I&C-1	2	I&C Improvements	\$ 70,000
PF-I&C-2	1	Control System Upgrade	\$ 2,323,000
PF-SITE-1	2	Stop Log Removal System for Effluent Gates	\$ 240,000
PF-SITE-2	2	General Site Improvements	\$ 112,000
PF-ARCH-1	2	Architectural Rehabilitation	\$ 351,000
PF-SAFE-1	1	Safety Improvements	\$ 126,000

12.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 12-27. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 12-27. Capital Improvement Plan Projects for Puritan-Fenkell CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
PF-1 Convert to Complete Capture Basin	\$ 2,600,000	2030 <i>Timing based on general CSO project priorities</i>	PF-WWMP-1	Convert to Complete Capture Basin	\$ 2,600,000
PF-2 Disinfection System Improvements	\$ 603,000	2032 <i>Timing based on asset condition</i>	PF-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 383,000
			PF-DIS-2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
PF-3 Flushing System Improvements	\$ 616,000	2032 <i>Timing based on best judgement</i>	PF-FD-1	Wet Well Improvements	\$ 79,000
			PF-FD-2	Provide Access to Tipping Buckets for Maintenance	\$ 95,000
			PF-FD-3	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
			PF-SITE-1	Stop Log Removal System for Effluent Gates	\$ 240,000
			PF-SITE-2	General Site Improvements	\$ 112,000
PF-4 HVAC Improvements	\$ 810,000	2027 <i>Timing based on asset condition</i>	PF-HVAC-1	HVAC Improvements	\$ 810,000
PF-5 Facility-Wide Electrical and I&C Improvements	\$ 2,598,000	2029 <i>Timing based on asset condition</i>	PF-ELEC-1	Electrical Improvements	\$ 205,000
			PF-I&C-1	I&C Improvements	\$ 70,000
			PF-I&C-2	Control System Upgrade	\$ 2,323,000
PF-6 Facility-Wide Safety and Architectural Improvements	\$ 477,000	2023 <i>Project should be initiated as soon as possible</i>	PF-ARCH-1	Architectural Rehabilitation	\$ 351,000
			PF-SAFE-1	Safety Improvements	\$ 126,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 12-28 and Table 12-29 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 12-29 indicates that PF-DIS-1 project has one asset that needs to be replaced immediately due to condition score of "5". This asset, however, has already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining nine assets that are included in this project have an average condition score of 1.27 and an average replacement date of 2032 (See Table 12-28). This information was used to propose a scheduled construction completion date of 2032.

Table 12-28. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST

12.3.3 20-Year Capital Outlay Plan

Table 12-30 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 12-30. 20-Year Capital Outlay Plan for Puritan-Fenkell CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System

Total	\$ 8,527,553	\$ 222,386	\$ 230,654	\$ 2,072,341	\$ 363,445	\$ 574,337	\$ 256,664	\$ 623,437	\$ 2,227,376	\$ 1,769,773	\$ 129,839	\$ 29,886	\$ 27,416

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Two influent slide gate (SG-1 and SG-5; \$157,000 each) received a score of 5 since they were locked out of service at the time of the Condition Assessment.
- HVAC System: One AHU (HV-1, \$63,500) was out of service at the time of inspection. Two electric unit heaters (\$19,500 each) , two supply fans (SF-3 and SF-4; \$3,000 each), and two exhaust fans (EF-7 and EF-8; \$2,600 each) received a score of 5 due to severe corrosion on the units and have been out of service for some time.

13. Seven Mile CSO Control Facility

13.1 General Facility Description and Future Capacity Considerations

13.1.1 General Facility Description

The Seven Mile CSO Facility is an RTB with 2.2 MG of storage and a treatment capacity of 655 cfs through the treatment system. It was constructed in 1997. Since it was constructed, the facility has rarely discharged, with one recorded event of 490,000 gallons of discharge in 2014 from a nearly 6-in. rain event. For this reason, Section 13.1.2 describes potential modifications to make this facility into a "Capture-Only" facility. A similar recommendation is made for the Puritan-Fenkell CSO Facility.

The facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

13.1.2 Modifications to Make Seven Mile Facility into a Capture-Only Facility (SM-WWPM-1)

The WWMP recognized that "GLWA has developed a protocol to operate the Puritan-Fenkell and Seven Mile basins in capture-only mode (no treatment or discharge) for flows up to the 10-year 1-hour design storm. This finding provides a significant water quality benefit because the 1,114-acre service area can be captured, stored, and returned to the WRRF following a storm event preventing release of an estimated 700 million gallons of combined sewer overflow each year."

Operating these two facilities in capture mode would allow for the cost avoidance of operating and maintaining the hypochlorite feed and storage systems, and it would likely not require operations labor to be onsite during a storm event.

Wade Trim conducted a study ("Puritan-Fenkell and Seven Mile CSO Retention and Treatment Basins Basin Collection System and Hydraulic Analysis", dated August 29, 2019). This hydraulic study included an analysis "to evaluate the potential of operating the basins in capture-only mode as a possible operational protocol for the system. Capture basin operation was evaluated to understand the impacts on untreated overflow from the 17 Main Rouge River outfalls on the Detroit West Side system, flooding impacts of the utility tunnels within the two basins, and the risk of upstream basement flooding."

The findings of the study included:

- Limited (approximately 2 percent) increase in untreated overflow from the 17 Main Rouge River outfalls as a result of capture mode operation.
- Impact to the utility tunnels when operating in capture mode is expected for design storms between the 10-year, 24-hour and the 25-year, 24-hour storm at the Puritan-Fenkell basin. At the Seven Mile basin, design storms slightly smaller than the 10-year, 24-hour storm will begin to impact the utility tunnel.
- The evaluation of basement flooding risk shows the basins can be operated in capture mode for the 10-year, 24-hour storm without risk of basement flooding. However, during the 25-year, 24-hour storm significant basement flooding can be expected.

The report concluded that operating the basins in capture-only mode in their current configuration is not recommended due to the risk of basement flooding. The report indicated, however, that capture-only

mode may be possible if high level emergency overflows are added to the basins to relieve the system during extreme events to protect basements from flooding.

To aid in the analysis of operating both Puritan-Fenkell and Seven Mile as capture-only basins, conceptual cost estimates have been generated under CS-299 for both facilities including capital improvements listed below. The Wade Trim hydraulic study provided some details regarding these issues, which are included in the description of the conceptual cost estimate; however, additional study and design will be needed.

- 1) Emergency overflow relief. The current weir wall is about 12 ft high at both facilities. A new weir wall about 20 ft high and associated structural modifications are needed at the effluent end of the basin to construct a taller weir wall. The length of weir was not reported and should be included in the future study.
- 2) Utility tunnel flooding protection. Water-tight doors are recommended where there is access to the basin from the utility tunnel and at the influent end of the utility tunnel. The proposed doors can withstand 20 ft of static head.
- 3) Replace the existing effluent butterfly gates with flap gates. The Wade Trim report evaluated two different locations for these gates at each facility, which would prevent backflow into the facility (see Figure 13-1 below showing one of the locations, which was used for the cost estimate). Additional study should be performed to determine if these flap gates are still needed with the taller proposed weir wall.

Figure 13-1. Potential Options for Flap Gate Retrofit – Seven Mile (from Wade Trim report)

A preliminary life-cycle comparison is presented in Table 13-1. Alternative 1 represents the scenario where the facility continues to operate as an RTB. Alternative 2 represents a scenario where the facility operates in the complete capture mode. The intent of this comparison is to present the cost of the emergency overflow weirs and flap gates compared to the avoided costs associated with maintaining the disinfection system and flow meters for the flow-through treatment mode of operation. The following costs are used in this evaluation:

- The period of evaluation is assumed to be 50 years, which represents an approximate remaining life of the basin.
- For Alternative 1, the capital costs were obtained from the SRP replacement costs and include the chemical feed pumps, drives, piping, and storage tanks. It also includes the flow meters for the

effluent and shunt channel. It is assumed for this analysis that all of these assets would be replaced twice during the period of evaluation.

- For Alternative 1, the O&M costs include those items that are currently needed, but would no longer be needed under a complete capture mode. These costs include Operations labor before and during storm events to make the facility ready for discharge, if necessary (assumed to be 8 storm events per year and 10 hours per storm event). Costs also include hypochlorite usage or degradation of one tank (2,400 gallons) every six months at a unit cost of \$0.90 per gallon.
- For Alternative 2, the total project cost for the modifications described for the emergency weirs and flap gates is provided in Volume 6 – Appendices, Appendix C, under SM-WWMP-1. The costs also include Permitting and Modeling to demonstrate and coordinate the modifications with Michigan EGLE (assumed to be \$100,000).

As shown in Table 13-1, the Best Value Alternative is Alternative 2 – Convert to Complete Capture Basin. As such, it is recommended that this alternative be pursued through additional modeling to confirm water levels in the collection system during peak storm events and coordination with Michigan EGLE.

Table 13-1. Alternative Evaluation for Seven Mile to Convert to Complete Capture Basin

Alt.	Description			Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.		Health and Safety	2	2.50	\$ 2,531,000	\$ 12,320	\$ 3,232,823	\$ 1,293,129	
	<i>Definition:</i>	Do nothing. Continue to operate as an RTB		Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system; no new regulatory issues		Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher level of operator attention during storm events. Must maintain hypochlorite storage and feed system.		Component Performance	3						
	<i>Comments:</i>	None		O&M Ease	2						
2	<i>Alt. Name:</i>	Convert to Complete Capture Basin		Health and Safety	4	3.72	\$ 2,500,000	\$ -	\$ 2,500,000	\$ 672,646	Best Value Alternative
	<i>Definition:</i>	Convert to Complete Capture Basin		Water Quality & Compliance	3						
	<i>Adv.:</i>	Less operator attention during storm events. No O&M for hypochlorite system.		Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires regulatory approval; Modeling confirmation of acceptability		Component Performance	3						
	<i>Comments:</i>	None		O&M Ease	5						

13.2 Facility Assessment

13.2.1 Screening

13.2.1.1 Description of Existing System

The Seven Mile CSO Facility has two bar screens that were installed in 1997. Influent wastewater enters the facility from the Seven Mile Sewer and is routed through the screens to the basin compartments. Material collected by the screens is mechanically raked from the bar screens and deposited into individual dumpsters to be hauled to a landfill.

It should be noted that this facility is planned to become a complete capture facility with emergency overflow to prevent basement flooding based on the recommendations from the WWMP. It is recommended that the screens remain at the facility to prevent large debris from entering the facility.

Table 13-2 provides an overview of the existing screening system at Seven Mile CSO facility.

Table 13-2. Overview of Existing Screening System at Seven Mile CSO Facility

Parameter	Value
Treatment Capacity (cfs)	655
No. of Screens	2
Manufacturer	E & I Corporation
Screen Type	Catenary Bar Screen
Opening Size	0.5-in. spacing
Depth or Length / Width	23 ft 0 in. / 9 ft 6 in.
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

13.2.1.2 Identified Needs and Issues

There were no needs identified by GLWA or the Jacobs team.

13.2.1.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no screening-related issues that that would be classified as capital improvement "needs."

13.2.2 Disinfection

13.2.2.1 Description of Existing System

This facility was constructed in 1996 and has rarely discharged. Recent studies have been conducted under the WWMP recommending that this basin be modified from a treatment basin to a complete capture basin. Under this scenario, the disinfection system would not be used. As such, it is recommended that the disinfection system be removed or moth-balled at this site.

Table 13-3 provides an overview of the existing disinfection system at Seven Mile CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 13-3. Overview of Existing Disinfection System at Seven Mile CSO Facility

Parameter	Value
Treatment Capacity (cfs)	655
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L Cl ₂)	10 @ 655 cfs
Disinfection Contact Time (min)	30
Storage Tanks Number Volume of Each Tank (gal) Type	2 2,400 FRP
Pumps Number Capacity (gpm) Type	4 20 Gear
Mixers Number / Type Model Number/ hp / Manufacturer	1 / Chemical induction mixers Series 32 / 10 hp / Gas Mastrrr

13.2.2.2 Identified Needs and Issues

The disinfection system should ultimately be demolished and removed from this facility. This includes the chemical storage tanks, chemical feed pumps, piping and associated electrical and instrumentation components. These costs are included in the conversion to a complete capture basin.

13.2.2.3 Description and Evaluation of Alternatives

There were no disinfection-related issues identified by the GLWA or the Jacobs team that would be classified as capital improvements “needs”.

13.2.3 Odor Control

13.2.3.1 Description of Existing System

The Seven Mile odor control system consists of one cross-current vertical scrubber vessel that treats air from the Headworks area and basins. The system includes a scrubber tower, recirculation pump, caustic addition system, sodium hypochlorite addition system and an odor control fan. The scrubber tower contains 5.5 ft of plastic media with a chemical spray section located above the media. The original system was designed to feed sodium hydroxide and sodium hypochlorite; however, the sodium hydroxide has not been used for some time.

The system was installed in 1997. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past three years.

13.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack.

Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous. Prior to implementing either one of these options, GLWA could sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water.

13.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement “needs”.

13.2.4 Flushing and Dewatering

13.2.4.1 Description of Existing System

Dewatering System: There are three dewatering pumps and one sump pump used to dewater the basin after a storm event. Dewatered flow is pumped to the NWI.

Flushing System: There are 14 tipping buckets on the side walls of both basin compartments and the influent channels. City water is used to fill the tipping buckets.

Table 13-4 provides an overview of the existing flushing and dewatering system at Seven Mile CSO facility.

Table 13-4. Overview of Existing Flushing and Dewatering System at Seven Mile CSO Facility

Parameter	Value
Total Basin Volume (MG)	2.2
Headworks and basin Dewatering and Flushing System	- There are three 2,000 gpm dewatering pumps 6 tipping buckets for each basin (12 total) 2 tipping buckets in influent distribution channel

13.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Provide access to tipping buckets for inspection
- Provide access to dewatering force main for inspection and cleaning

13.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Access to Tipping Buckets (Project SM-FD-1). O&M staff noted that the bearing assemblies for the tipping buckets are inaccessible; however, they require periodic inspection and greasing.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Access to Tipping Buckets for Maintenance.** This alternative provides access for visual inspection of the tipping bucket bearing assemblies consists of constructing manhole openings above each adjoining set of rotating groups. A total of 17 manhole openings would be required, including one over each bearing assembly on the end tipping buckets.

Installation will require removing pavement and excavating to the top of the existing roof slab. A 24-in. opening will be cored through the roof, and manhole grade rings set/doweled over the opening and extended to the existing surface. A standard 24-in. manhole ring and lid will be set flush with the pavement, and the excavation backfilled around the new access point. Final restoration will include pavement repairs and patching to the concrete parking area.

The costs include extending a 0.5-in. metal grease tube and grease gun fitting from each bearing assembly to within 6 in. of the surface at the nearest new manhole opening (2 zerks per manhole, 1 each at the end tipping buckets). After consultation with the tipping bucket gate manufacturer, regular greasing of the bearings is not required for the model of tipping buckets installed at the Seven Mile CSO Facility. GLWA may elect to install the access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly. Figures (Figure SM-FD-1-ALT-2) included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

The alternative evaluation for these alternatives is presented in Table 13-5. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and increased ease of O&M provided by the improved access to the tipping bucket bearings. The NPV/Benefit cost for Alternative 2 is \$36,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Tipping Buckets is the recommended alternative.**

Table 13-5. Alternative Evaluation for Access to Tipping Buckets (Project SM-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Inaccessible bearing assemblies for the tipping buckets	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Access to Tipping Buckets for Maintenance	Health and Safety	4	3.50	\$ 125,000	\$ -	\$ 125,000	\$ 35,714	Not Applicable
	<i>Definition:</i>	Construct manhole openings over each bearing assembly of tipping buckets	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access for better visual confirmation of tipping bucket condition and operation and better	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Dewatering Force Main (Project SM-FD-2). GLWA noted that the force main from the CSO facility to the NWI is inaccessible but will require future inspection and cleaning.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Access to Dewatering Force Main for Inspection and Cleaning.** this alternative consists of the installation of cleanouts at the following locations: 1) at the end of the force main, southwest of the siphon head chamber in Manhole No. 1 for cleaning of the force main, 2) just to the northeast of the Manhole No. 1 before the inverted siphon, and 3) east side of the Rouge River, just before Manhole No. 2. (see Figure SM-FD-2-ALT-2 included in Volume 6 – Appendices, Appendix B)

The alternative evaluation for these alternatives is presented in Table 13-6. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M provided by the ability to access the force main. The NPV/Benefit cost for Alternative 2 is \$28,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Dewatering Force Main is the recommended alternative.**

Table 13-6. Alternative Evaluation for Access to Dewatering Force Main (Project SM-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Dewatering forcemain from the CSO facility to the NWI remains inaccessible.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Access to Dewatering Force Main for Inspection and Cleaning	Health and Safety	3	3.22	\$ 90,000	\$ -	\$ 90,000	\$ 27,979	Not Applicable
	<i>Definition:</i>	Install cleanouts at a number of locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access to the dewatering forcemain from the CSO facility to the NWI for future inspection and cleaning.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.5 HVAC

13.2.5.1 Description of Existing System

The Seven Mile CSO facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard. The facility also includes the retention basins. Table 13-7 provides summary of the major HVAC equipment for the facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, multiple emergency shower/eye wash, regular shower, and sump pump. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 13.2.10.

Table 13-7. Major HVAC Equipment at Seven Mile CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-2	Heating and Ventilating Unit	12,190 CFM
	EF-5	Exhaust Fan	11,480 CFM (Pump Area)
Basin	SF-1 and 2	Supply Fan (for Basin)	102,420 CFM
	SF-3	Supply Fan (Utility Tunnel)	1,472 CFM
	SF-4	Supply Fan (Shunt Channel)	2,600 CFM
	EF-7	Exhaust Fan (Shunt Channel)	500 CFM
	EF-8	Exhaust Fan (Effluent Channel)	500 CFM
	UH-1 and 2	Unit Heater (Shunt Chamber)	400 CFM 17.0 MBH
Odor Control Room	HVU-1	Heating and Ventilating Unit	2,400 CFM 65 MBH
	EF-6	Exhaust Fan	2,000 CFM
Basement (Meter Vault)	HVU-3	Heating Ventilation Unit	1,200 cfm
Electrical Room	PACU-1	Packaged Air Conditioning Unit	2,200 CFM 51.2 MBH

Table 13-8 provides a summary of the basis of design performance criteria for HVAC systems at Seven Mile and Table 13-9 provides the outdoor Basis of Design conditions.

Table 13-8. Seven Mile Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Retention Basin	Class I, Div 1, Group D	N/A	N/A	10 ACH
Headworks and Pump Room	Class I, Div 1, Group D	60	N/A	12 ACH

13.2.5.2 Identified Needs and Issues

During the Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- PACU-1 requires replacement.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- PACU-1 requires frequent maintenance to keep running: GLWA's HVAC contractor noted that PACU-1 at Seven Mile has had issues very similar to unit at Puritan-Fenkell, including damper problems, actuator problems, refrigerant leaks and wiring issues.
- SF-1 and SF-2 motorized dampers are not fully functional.
- SF-2 has audible motor bearing problems.

During site investigations (June 2020), the following observations were noted:

- SF-1 and SF-2 were functional but had damaged duct connections.
- The motorized dampers for SF-1 and SF-2 were seized and not fully open.
- HVU-3 is difficult to access for maintenance.

13.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project SM-HVAC-1). Due to the numerous HVAC-related assets that require replacement and the additional need to provide monitoring for code compliance in the Odor Control Room and Headworks, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. As such, there is only one alternative for this project, which includes:

- PACU-1 Replacement
- Improvements to Enhance Safety in Odor Control Area

- Improvements to Enhance Safety in Headworks Area
- HVU-1 and 2 Replacement
- HVU-3 Replacement (with improved access)
- SF-1 and SF-2 Replacement
- Exhaust Fan Replacement
- Removal of Shunt Channel and Effluent Channel HVAC Equipment

Each of the HVAC-related improvements listed above are described further below:

PACU-1 Replacement. Given the age of PACU-1 (24 years) and the lengthy history of various issues, replacement of PACU-1 with a more efficient modern unit and controls is recommended.

Improvements to Enhance Safety in Odor Control Area. The Odor Control area is classified as a Class I, Division 2 space under NFPA 820 if it is not continuously ventilated at a rate of 6 ACH. The space does not meet the 6 ACH ventilation requirement and does not currently have electrical equipment rated for a Class I, Div 2 environment. HVU-1 is designed to provide 10 ACH of ventilation air in cooling mode but was sized to provide only 2 ACH of outside air in heating mode. Additionally, EF-2 is only designed to operate in cooling mode at 10 ACH. NFPA 820 requires both supply and exhaust fans to operate continuously to unclassify odor control areas.

Given the age of HVU-1 and EF-2 and the problems HVU-1 is exhibiting, Jacobs recommends in-kind replacement of both units. HVU-1 and EF-1 could be replaced with two-speed fans or VFDs to provide 6 ACH continuously during ventilation and heating and 10 ACH in cooling mode.

Regardless of whether the space is unclassified by providing 6 ACH of outside air, NFPA 820 requires the installation of combustible gas detection in the Odor Control area with audible and visible alarms at all entrances to the Odor Control area and within the space.

If ventilation is used to unclassify the space as described above, ventilation flow monitoring of both the supply and exhaust fan is required with visible and audible alarms of a low or no flow condition required at entrances and within the space.

Improvements to Enhance Safety in Headworks Area. HVU-2 serves the Headworks Area, which is classified as a Class I, Division 1 space per the design drawings. Given its age and general condition, HVU-2 should be replaced. Because the electrical equipment in the space is rated for a Class I, Division 1 environment continuous ventilation and ventilation flow monitoring are not required. NFPA 820 does, however, require combustible gas detection with visible and audible alarms at the entrances to the Headworks area and inside the space, which the Headworks area currently does not have. Jacobs recommends making this change to comply with NFPA 820.

HVU-3 Replacement (relocated with improved access). HVU-3 is currently mounted high in the Metering Room space making access for maintenance very difficult (Figure 13-2). Placing HVU-3 lower in the space would make access to the magnetic meter and associated piping very difficult. Jacobs recommends replacing HVU-3 with a unit mounted on a concrete pad on the North side of the building when HVU-3 requires replacement. There is an existing opening for the Meter Room supply air duct, which could be utilized by the outdoor unit. This approach would allow ample space for maintenance and would make removal much easier. Currently, HVU-3 will need to be removed in sections when replacement is necessary.

Figure 13-2. HVU-3 Located in Inaccessible Area Difficult to Access Location

SF-1 and SF-2 Replacement. SF-1 and 2 are functional despite having damaged duct connections. These units will require replacement in the near future. The motorized dampers on the units have seized and will need to be removed or replaced. It is worth noting that the design documents for the Puritan-Fenkell facility (which is very similar to Seven Mile Road) indicated the Basin ventilation units had motorized dampers, which were not seen during the site walkthrough and presumably have since been removed. Motorized dampers are not necessary for this application and add a potential failure point as well as increased maintenance and repair costs. The selection of fans with corrosion-resistant construction should negate the need to have motorized dampers.

Exhaust Fan Replacement. There are five relatively small exhaust fans that are original to the facility and should be included in the replacement project.

Removal of Shunt Channel and Effluent Channel HVAC Equipment. The unit heater, supply and exhaust fans in the Shunt Channel and Effluent Channel are not used and are inoperable. These units could be retired. Portable ventilation could be utilized, if necessary, when operators need to enter these areas.

The alternative evaluation is presented in Table 13-10. **The capital cost for Alternative 1, which is the recommended alternative,** is included in Volume 6 – Appendices, Appendix C under this project title.

Table 13-10. Alternative Evaluation for HVAC Improvements (Project SM-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	3	3.00	\$ 858,000	\$ -	\$ 858,000	\$ 286,000	Best Value Alternative
	<i>Definition:</i>	Facility-wide HVAC Improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, less emergency maintenance, improved asset reliability.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

13.2.6 Electrical

13.2.6.1 Description of Existing System

The Seven Mile facility's electrical system consists of one DTE utility feed from a 750 kVA, 480/277 V, 3-Phase outdoor transformer (secondary metering) and one diesel generator feed from a 350 kW, 480/277 V, 3-Phase stationary generator. The feeds are connected to a 1,200 A MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP has breakers that feed MCCs and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 13-11 provides a summary of the major electrical equipment for this facility.

Table 13-11. Major Electrical Equipment at Seven Mile

Location	Major Electrical Equipment	Description
Electrical Room	Main distribution panel with ATS	1,200 A, 480/277 V, 3-Phase
Courtyard	Generator (Diesel)	350 kW, 480/277 V, 3-Phase
Electrical Room	MCC-1	400 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	400 A, 480/277 V, 3-Phase

13.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

13.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project SM-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure SM-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the basins. Lighting to meet the required foot-candles and codes for the area.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including additional power receptacles at the facility's outfall.

The alternative evaluation is presented in Table 13-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$39,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 13-12. Alternative Evaluation for Electrical Improvements (Project SM-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 136,000	\$ -	\$ 136,000	\$ 38,857	Not Applicable
	<i>Definition:</i>	Add additional lighting in basins. Provide exterior power receptacles.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.7 I&C

13.2.7.1 Description of Existing System

Control System: The original PLC control system and hardwired backup control system were installed in 1996 under PC-696. The system has the ability to remotely monitor the operations of the facility and the overall area collection system at SCC.

The existing control system consists of Allen Bradley redundant PLC-5 processors with local I/O for monitoring and control of the facility processes. The system has hardwired backup capabilities to control the facility on an overall control system failure. The PLC's control system network communicates via an Ethernet network to the facility's control system and operator workstation. The workstation currently uses the Rockwell RSView software package that provides the existing operator workstation the additional software applications to provide historical data storage and retrieval, reporting, as well as other functions to monitor and control the system. The local hardwired backup control panel is obsolete and with new redundant control systems, this type of backup hardwired control panel is no longer used. The current system is equipped with a backup radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 13-13 summarizes the level sensors and flow meters at the Seven Mile CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 13-13. Summary of Flow Meters and Level Sensors at Seven Mile CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Shunt Channel	1	Transit-Time (AccuSonic)
Effluent Weir	2	Ultrasonic
Dewatering	1	Magnetic
CSO Level Sensors		
Influent	1	Ultrasonic
Screening Area (Downstream of bar racks)	1	Ultrasonic
Basin	2	Ultrasonic
Effluent Channel	1	Ultrasonic
Dewatering Well	1	Ultrasonic
NWI	1	Ultrasonic
River	1	Ultrasonic
Chemical System Flow Meters		
Secondary Water	1	Magnetic
Chemical Feed	1	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic

13.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Update control system. GLWA is currently developing a RFPs for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under "Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities." The project will replace the existing PLC-5 control system and backup local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an ongoing project that has already been included in the CIP.

13.2.7.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no I&C related issues that that would be classified as capital improvement "needs."

13.2.8 Site

13.2.8.1 Description of Existing Site

The Seven Mile CSO Facility was constructed in 1994. Access to the site is off of Shiawassee St. through a 25-ft wide sliding gate. Site security is provided by perimeter fencing comprised of a 6-ft high chain-link fence along the west side of the CSO building along Shiawassee St. The parking lot consists of 4-in. thick asphalt pavement with 8-in. gravel base. Concrete sidewalks are 5 ft wide and 4 in. thick with 4-in. sand base. The top of most of the basin roof area is used as a parking lot by the nearby church.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

13.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- There is no security fencing around the north, south and east sides of the Seven Mile CSO Control/Headworks Building.
- The Courtyard floor does not provide adequate slope for the rain/snow runoff to flow to the scuppers and consequently ponds on the floor surface.
- The existing hatch cover plates are heavy and difficult to remove.

13.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Security Fencing (Project SM-Site-1). There is currently no security fencing around the north, south and east sides of the Seven Mile CSO Control/Headworks Building. Painted chain-link fencing exists on the west side of the CSO building along Shiawassee St. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Extend Security Fencing Around Entire Building.** It is recommended that security fencing be installed along the remainder of the building site to secure building operations.

The alternative evaluation is presented in Table 13-14. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.9 higher than the Do Nothing Alternative (Alternative 1) based on the improved safety. Because of the importance of this issue related to safety, **Alternative 2 – Extend Security Fencing Around Entire Building is the recommended alternative.**

Table 13-14. Alternative Evaluation for Security Fencing (Project SM-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Security issue.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Extend Security Fencing Around Entire Building	Health and Safety	5	3.57	\$ 347,000	\$ -	\$ 347,000	\$ 97,290	Not Applicable
	<i>Definition:</i>	Security fencing to be installed along the remainder of the building site.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Secure building operations	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

Site Improvements (Project SM-SITE-2). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Improve Drainage in the Courtyard
 - Replace Existing Effluent Gate and Shunt Channel Hatches

Each of the site related improvements listed above is described further below:

Improve Drainage in the Courtyard. The Courtyard at the Headworks of the Seven Mile CSO Basin has an open roof and is exposed to rain and snow falling on the floor surface. There are scuppers in the base of the east wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface. To alleviate the water ponding, it is recommended that holes be cored through the courtyard floor to the basin below. Recessed area drains can be installed in the cored holes to funnel floor drainage to the basin.

Replace Existing Effluent Gate and Shunt Channel Hatches. There are three hatch openings over the three existing effluent butterfly gates and their corresponding stop log guides. The hatch openings at the effluent gates have dimensions of 8 ft by 3 ft. The existing hatch cover plates are heavy and difficult to remove. GLWA would like to replace cover plates with an alternative plate design that improves accessibility to the gates and stop log guides below.

There are also two hatch openings over the two shunt channel butterfly gates and their corresponding stop log guides. These hatch openings also have dimensions of 8 ft by 3 ft. These hatch covers have been recently replaced and are not included in the cost estimate.

The improvements at these locations should be coordinated with the potential modification of this basin to a complete capture facility, described in Section 13.1.2.

The alternative evaluation is presented in Table 13-15. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$35,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 13-15. Alternative Evaluation for Site Improvement (Project SM-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety issues.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 122,000	\$ -	\$ 122,000	\$ 34,857	Not Applicable
	<i>Definition:</i>	Improve drainage in the Courtyard and replace existing effluent gate and shunt channel hatches.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved drainage and ease of O&M.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.9 Architectural

13.2.9.1 Description of Existing Facilities

The Seven Mile Road CSO facility consists of chemical room, utility support (electrical), control room, work room, odor control room, screen room, miscellaneous other rooms and a courtyard.

13.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 13-16. As such, the roof should be replaced in-kind and the costs and schedule for the roof replacement will come from the SRP.

Table 13-16. 60-Year Life-Cycle Cost Evaluation of Shingled vs. Metal Roof for Seven Mile Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$93,000	\$311,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life-Cycle Cost (NPV) Discounted at 2.4%	\$252,000	\$311,000

^a Based on 6,225 ft² roof area; \$15 ft² for shingle roof and \$50/ ft² for metal roof.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that that there is no access to the Headworks area and the Courtyard during a power outage.

13.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (SM-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove corrosion at bottom of man door and coat steel framing
 - Remove paint debonding from wall, clean and coat
 - Address door hardware issues
 - Remove painted debonding from roof framing, clean and coat

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure SM-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 13-17. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 13-17. Alternative Evaluation for Architectural Rehabilitation (Project SM-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 156,000	\$ -	\$ 156,000	\$ 50,323	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

Access to Courtyard and Headworks (Project SM-ARCH-2). If there is a power outage and the generator does not kick on, there would be no access to the Headworks area and the Courtyard. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Additional Access to Courtyard and Headworks.** GLWA requested access doors be provided from the Courtyard to the outside. Two 3-ft by 7-ft heavy-duty hollow metal double doors and frame with commercial grade stainless steel hardware is recommended to provide emergency access.

The alternative evaluation is presented in Table 13-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$10,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Additional Access to Courtyard and Headworks is the recommended alternative.**

Table 13-18. Alternative Evaluation for Access to Courtyard and Headworks (Project SM-ARCH-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No access to the Headworks and Courtyard, during a power outage.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Additional Access to Courtyard and Headworks	Health and Safety	4	3.50	\$ 34,000	\$ -	\$ 34,000	\$ 9,714	Not Applicable
	<i>Definition:</i>	Install door into Courtyard.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Provides emergency access to the Headworks and Courtyard during a power outage.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.10 Safety

13.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

13.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 13-19. The capital improvement project to address these issues is included in the table.

Table 13-19. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Chemical Room	Emergency eyewash/shower 0943390 outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project SM-SAFE-1)
Utility Tunnel	Ladder at end of tunnel has an exit sign but hatch is locked.	Add placard to fixed ladder "Not An Exit." Replace existing exit sign with directional exit sign away from ladder access.	Exit Sign Improvements ^a

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

13.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project SM-SAFE-1). This project should address the safety issues identified above. These issues include:

- Add eyewash/shower outside containment in the Chemical Room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency, the Table 13-20 showing the one alternative is presented below.

Table 13-20. Alternative Evaluation for Safety Improvements (Project SM-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 92,000	\$ -	\$ 92,000	\$ 30,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

13.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Seven Mile CSO Facility.

13.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Seven Mile CSO facility, Table 13-21 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 13-21, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 13-21. Listing of Asset Condition Assessments for Seven Mile Facility

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Three inactive pumps are listed in WAM - Basin 1 Sample Pump, Basin 2 Sample Pump, and Shunt Channel Sample Pump. These pumps are being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Seven Mile Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

13.3 Capital Planning for Seven Mile CSO Facility

13.3.1 Summary of Capital Improvement Plan Projects

Table 13-22 provides a summary of the recommended CIP projects and associated capital costs for the Seven Mile CSO facility based on the alternative evaluations conducted for this facility.

Table 13-22. Summary of Recommended Projects at Seven Mile CSO Facility

Project No.	Alternative	Description	Total Project Cost
SM-WWMP-1	2	Convert to Complete Capture Basin	\$ 2,500,000
SM-FD-1	2	Provide Access to Tipping Buckets for Maintenance	\$ 125,000
SM-FD-2	2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
SM-HVAC-1	1	HVAC Improvements	\$ 858,000
SM-ELEC-1	2	Electrical Improvements	\$ 136,000
SM-I&C-1	1	Control System Upgrade	Ongoing Project
SM-SITE-1	2	Extend Security Fencing Around Entire Building	\$ 347,000
SM-SITE-2	2	Site Improvements	\$ 122,000
SM-ARCH-1	2	Architectural Rehabilitation	\$ 156,000
SM-ARCH-2	2	Additional Access to Courtyard and Headworks	\$ 34,000
SM-SAFE-1	1	Safety Improvements	\$ 92,000

13.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 13-23. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 13-23. Capital Improvement Plan Projects for Seven Mile CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
SM-1 Flushing Improvements	\$ 337,000	2032 <i>Timing based on Best judgement</i>	SM-FD-1	Provide Access to Tipping Buckets for Maintenance	\$ 125,000
			SM-FD-2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
			SM-SITE-2	Site Improvements	\$ 122,000
SM-2 HVAC Improvements	\$ 858,000	2027 <i>Timing based on asset condition</i>	SM-HVAC-1	HVAC Improvements	\$ 858,000
SM-3 Electrical Improvements	\$ 136,000	2032 <i>Timing based on best judgement</i>	SM-ELEC-1	Electrical Improvements	\$ 136,000
SM-4 Facility-Wide Safety and Architectural Improvements	\$ 629,000	2023 <i>Project should be initiated as soon as possible</i>	SM-SITE-1	Extend Security Fencing Around Entire Building	\$ 347,000
			SM-ARCH-1	Architectural Rehabilitation	\$ 156,000
			SM-ARCH-2	Additional Access to Courtyard and Headworks	\$ 34,000
			SM-SAFE-1	Safety Improvements	\$ 92,000
SM-5 Convert to Complete Capture Basin	\$ 2,500,000	2030 <i>Timing based on general CSO project priorities</i>	SM-WWMP-1	Convert to Complete Capture Basin	\$ 2,500,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 13-24 and Table 13-25 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 13-24 indicates that SM-HVAC-1 project has 12 assets that has an average condition score of 1.61 and an average replacement date of 2034. Although the average replacement date suggests 2034, the SM-HVAC-1 project was moved up to 2027 due to equipment age and performance.

Table 13-24. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
SM-HVAC-1	12	1.19	1.61	2.15	20	2034	\$ 224,880

Table 13-25. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
SM-HVAC-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

13.3.3 20-Year Capital Outlay Plan

Table 13-26 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 13-26. 20-Year Capital Outlay Plan for Seven Mile CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System

2039	\$ 521,153	\$ 18,877	\$ -	\$ -	\$ 68,097	\$ 356,888	\$ 22,302	\$ 54,989	\$ -	\$ -	\$ -	\$ -	\$ -
2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 6,945,682	\$ 106,262	\$ 293,797	\$ 2,045,001	\$ 438,169	\$ 810,288	\$ 88,549	\$ 295,060	\$ 847,591	\$ 1,769,773	\$ 223,776	\$ -	\$ 27,416

- Notes:
- Explanation of large capital outlays in first two years:
- Retention System: Two influent slide gate (SG-1 and SG-5; \$157,000 each) received a score of 5 because the gates were locked out at the time of the Condition Assessment. Two flushing water ball valve (FW-1 and FW-8; \$4,000 each) received a score of 5 because the actuator for the valve was not functional or had been removed.

14. St. Aubin CSO Control Facility

14.1 General Facility Description and Future Capacity Considerations

14.1.1 General Facility Description

The St. Aubin CSO Facility is an SDF with 2.4 MG of storage, and a treatment capacity of 250 cfs. It was constructed in 2002. The facility has a nearly 1/3-mile long effluent conduit used for disinfection contact time before discharge into the Detroit River. The facility consists of an underground headworks, chemical room, odor control area, supply fan room, control room, and utility support (electrical, emergency generator, and mechanical rooms) and a restroom. The facility has an offsite sample building at the end of the outfall.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

14.1.2 Future Capacity Considerations

Based on a review of the WWMP, there were no future increased capacity considerations identified at this facility.

14.2 Facility Assessment

14.2.1 Screening

14.2.1.1 Description of Existing System

The St. Aubin CSO Facility has two vertical ROMAG screens that were installed in 2002. Screenings are retained in the influent chamber during the storm. After the storm event, the screenings are pumped to the Detroit River Interceptor for eventual removal at the WRRF.

Table 14-1 provides an overview of the existing screening system at St. Aubin CSO facility.

Table 14-1. Overview of Existing Screening System at St. Aubin CSO Facility

Parameter	Value
Treatment Capacity (cfs)	250
No. of Screens	2
Manufacturer	Westech ROMAG
Screen Type	Raked Vertical Bar Screens
Opening Size	4-mm spacing
Depth or Length / Width	3 ft 7 in. / 22 ft 0 in.
Screen Cleaning	Mechanical Comb
Screening Removal	Pumped to Toward Treatment Sewer and to WRRF

14.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- Evaluate potential improvements to existing screening system to remove screenings during wet weather.

14.2.1.3 Description and Evaluation of Alternatives

The evaluation of the need identified above is presented in this section.

Replace Screens with Improved Screens. Due to the configuration of the St. Aubin CSO Facility, the screenings accumulate during a wet weather event in the influent chamber in front of the screens. Although each screen has a mechanically operated comb that cleans the screens during a wet weather event, the screenings continue to accumulate in front of the screens. Some provisions were made in the original system to direct the screens to the dewatering well; however, these were found to be ineffective.

Jacobs investigated a new type of screen by Enviro-Care (SAVI Overflow Spillway – Model VSE-700/6) that could transport the screenings away from the influent chamber and convey them using an integral screw conveyor to the dewatering chamber (see Figure 14-1). The manufacturer developed a layout within the existing facility that would allow the screenings to discharge near the dewatering chamber. A short connection would be required to connect the discharge end to the facility's Dewatering Chamber.

Figure 14-1. Enviro-Care SAVI Overflow Spillway Screen

There are a number of concerns with the Enviro-Care screen and the retrofit of this screen into the St. Aubin facility:

- The proposed screen, within the given facility layout, only has a capacity of 217 cfs, which is less than the facility capacity of 250 cfs.
- The proposed screen has 8-mm openings. The other GLWA SDF with perforated openings (Baby Creek) has perforations of 6-mm. The Enviro-Care screen is available in 6-mm; however, the capacity of a screen with 6-mm perforations would be further reduced. Although the perforation size could potentially be negotiated with Michigan EGLE, there is a risk that EGLE would require 6-mm perforations.

Given the fact that the screen does not meet facility's design capacity of 250 cfs, it is not recommended for further consideration.

14.2.2 Disinfection

14.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, two low-rate diaphragm pumps, three high-rate diaphragm pumps, two rapid mix zones, and seven induction mixers. There are two ROMAG screens discharging into a screened effluent channel. From there screened effluent flows to two disinfectant rapid mix zones. There are three induction mixers per disinfectant rapid mix zone consisting of one pair of mixers upstream and one mixer downstream of a concrete baffle wall that directs all flow down and past the mixers. There is also one induction mixer in the influent channel upstream of screening referred to as prechlorination and the influent channel mixer. The discharges of Low-rate Pump 1 and High-rate Pump 2 combine and serve disinfectant rapid Mix Zone 1. The discharges of Low-rate Pump 3 and High-rate Pump 4 combine and serve disinfectant rapid Mix Zone 2. Sodium Hypochlorite Pump 5 serves the prechlorination mixer or as a backup to either rapid mix zone. Flow is metered from each pump and then flow is split in a manifold to the three induction mixers in each disinfectant rapid mix zone. The manifold includes a solenoid valve, manual valve, and a sight flow indicator to each induction mixer. Flow splitting between induction mixers is primarily dependent on equal back pressure valve settings to the induction mixers. Some valves are inaccessible due to their height on the wall.

Table 14-2 provides an overview of the existing disinfection system at St. Aubin CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 14-2. Overview of Existing Disinfection System at St. Aubin CSO Facility

Parameter	Value
Treatment Capacity (cfs)	250
Design Feed Strength (% hypochlorite)	10
Max. Dosage at Design Flow (mg/L Cl ₂)	38
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	5,200
Type	FRP
Pumps	
Number	5 Total; 2 low-rate, 5 high-rate
Capacity (gpm)	Low-rate: 7.6, High-rate: 22.8
Type	Hydraulic diaphragm
Mixers	
Number / Type	7 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC7.5FX / 7.5 hp / Water Champ

14.2.2.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations.

This facility, however, will be treated differently in this project because Hazen performed a Sodium Hypochlorite Storage and Feed System Assessment, dated October 15, 2019, for disinfection system improvements and AECOM is developing scope for an upcoming design project for facility improvements, including chemical feed pumps, relocation of pump control panels, mixer modifications, and building storage improvements.

Sodium Hypochlorite Feed and Storage System Improvements (Project STA-DIS-1). The recommendations from the Hazen report, although not identical, are similar to the chemical feed system improvements recommended in CS-299. Chemical feed pumps as peristaltic (hose) pumps or mag drive centrifugal pumps were recommended for further consideration during detailed design. It is recommended that the firm selected for detailed design consider the improvements from this CS-299 Facilities Assessment evaluation of the disinfection systems to best standardize this system with the other future systems. Other disinfection-related improvements were recommended as part of this project, including operation in automatic mode and provisions to flush the feed system piping.

14.2.2.3 Description and Evaluation of Alternatives

Because this is an upcoming project (CIP 260617), an alternative evaluation was not conducted, and capital costs are not included in this report.

14.2.3 Odor Control

14.2.3.1 Description of Existing System

The St. Aubin odor control system consists of a Calgon Carbon PHOENIX automatic regeneration system, which utilizes radial flow canisters filled with Centaur HP carbon. Several years ago, Calgon Carbon sold its odor control equipment division to Continental Carbon along with the Centaur HP carbon. The unit consists of 30 canisters and an odor control fan, which delivers air through the carbon filters or directly to the exhaust stack. Air is pulled from the screening and disinfection chambers by the odor control fan and is uniformly distributed through the carbon canisters, bringing the air in direct contact with the carbon. The regeneration process consists of programmed filling of a single compartment of canisters with water, letting the water sit for a period of time, and then draining and drying the carbon.

The system was installed in 2002. The carbon has not been replaced since installation. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past three years.

14.2.3.2 Identified Needs and Issues

The identified needs for the St. Aubin CSO facility are included in the following sections. The following issue was identified:

- Evaluate improvements to enhance safety around odor control system inside building, if needed.

Improvements to Enhance Safety Around Odor Control System. Hazen prepared a preliminary design report for the St. Aubin CSO Facility entitled *Sodium Hypochlorite Storage and Feed System Assessment*, dated October 15, 2019. In this report, they investigated the facility's current compliance with NFPA 820. Based on this evaluation, the following deficiencies were noted:

- Air flow monitoring
- Horns and strobes
- Backup power supply for horns/strobes and flow monitoring.

The Hazen report recommends that these items be included in the upcoming facility improvement project. This issue is being addressed in an upcoming project (CIP 260617).

The recommendations related to the odor control system below are based on the Jacobs team evaluation of the existing system.

Future Carbon Replacement Considerations. Centaur HP carbon contains a catalyst that oxidizes H_2S and converts it to sulfuric acid. As a result, the carbon can be restored for H_2S uptake by water washing. As discussed for the Baby Creek CSO Facility in Section 6.2.3.2, the Centaur HP carbon loses capacity over time. One typically determines the need for carbon regeneration by measuring the H_2S concentration in the discharged air. When H_2S is still detected in the discharged air after a regeneration cycle, the carbon is spent and should be replaced. Centaur HP replacement is about every two years under typical municipal wastewater applications. GLWA CSO facilities are not typical applications as the odor control systems are operated infrequently and are likely under low loads from H_2S and odorous compounds meaning the carbon will last a lot longer. According to O&M staff, the St. Aubin system is regenerated every two months based on the recommended PM in the manufacturer's O&M manual. The system may not need to be regenerated that frequently given the light load. The existing practice of carbon regeneration every two months may continue, but carbon capacity may decrease with each washing due to compounds in the regeneration water that adsorb to the carbon and that less than 100 percent of the sulfuric acid generated during the adsorption process is removed. Laboratory analysis of the carbon for H_2S capacity is likely the best way to determine the remaining carbon life for the St. Aubin system. Sampling the discharged air for H_2S breakthrough likely will not be an effective indicator due to the likely low H_2S load.

Although the current carbon capacity may be significantly less than the original capacity, the lack of any odor complaints from the community suggests that any odors being discharged are either not noticeable, not objectionable or are masked by other odor sources in the area. It is recommended that GLWA sample the influent and discharge of the odor control system during at least two storm events in the summer months (i.e., the period with the highest odor potential) to better understand the magnitude of odors generated from the CSO facility.

If the influent H_2S levels are low, replacement of the carbon would not be needed. Further testing could then be performed to determine if the carbon could be removed and not replaced. A non-detectable concentration of H_2S in the influent air means the system can likely operate without carbon. The following bullets provides considerations for the carbon replacement.

- The existing Centaur HP carbon in the PHOENIX system has an H_2S capacity of 0.09 g H_2S /cubic centimeter of carbon (15 percent by weight). The cost for replacement of the carbon is about \$20,400 (30 canisters at \$680/canister). The cost includes a new canister, sealing and loading the canister with Centaur HP carbon, and delivery.
- ECS manufactures a direct equivalent to Centaur HP carbon at a lower cost. ECS reuses the existing canisters. The cost for ECS's water regenerable catalytic carbon is about \$12,750 (30 canisters at \$425/canister). The cost includes shipping the full canisters to ECS, disposal of the spent carbon, cleaning the canisters, charging the canisters with ECS water regenerable catalytic carbon, and delivery.

As noted above, an evaluation of influent and discharge H_2S concentrations is recommended prior to carbon replacement. When it is time to replace the Centaur HP carbon, GLWA should evaluate replacing it with either Centaur HP or ECS water regenerable catalytic carbon.

14.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs".

14.2.4 Flushing and Dewatering

14.2.4.1 Description of Existing System

Dewatering System: The Headworks (screening and disinfection) area and the effluent conduits are dewatered after a storm event using three dewatering pumps located in the Headworks Dewatering Well.

The dewatering of the effluent conduit also relies on two submersible dewatering pumps located at the end of the effluent conduit. These pumps convey any water remaining at the end of the effluent conduit (after the Headworks Dewatering Pumps have removed as much of the water as possible) back to the Headworks Dewatering Well.

Flushing System: The original facility did not include a flushing system for the effluent conduits. Around 2010, a flushing system for the final one-third of the effluent conduits was installed. This system consists of two 100 gpm flushing pumps located at the outfall, just downstream of the backwater gates. These pumps use Detroit River water to pump to two locations in the effluent conduit with spray nozzles.

A manually operated, gravity flushing system consisting of a pipe with nozzles is provided for the area upstream of screens. This system uses water captured in the disinfection chambers as flushing water. The area upstream of the screens is dewatered first, while water remains in the mixing chambers. The head pressure from the water in the mixing chambers provides the pressure in the flushing pipe to provide a sufficient flush of the floor area.

Table 14-3 provides an overview of the existing flushing and dewatering system at St. Aubin CSO facility.

Table 14-3. Overview of Existing Flushing and Dewatering System at St. Aubin CSO Facility

Parameter	Value
Headworks Dewatering and Flushing System	- Headworks (screening and disinfection) area is dewatered using three 1,100 gpm dewatering pumps located in the Headworks Dewatering Well. - Manually operated flushing system consisting of a pipe with nozzles for area upstream of screens.
Effluent Conduit Dimensions	10 ft. × 10 ft.
Effluent Conduit Dewatering and Flushing System	- Effluent conduit is dewatered using three 1,100 gpm dewatering pumps located Headworks Dewatering Well. - There are two 200 gpm submersible dewatering pumps located at the end of the effluent conduit, which pump back to the Headworks Dewatering Well. - There are two 100 gpm flushing pumps that provide water to a spray flushing system for the second half of the effluent conduit.

14.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the flushing and dewatering system:

- Settled solids buildup in the 10-ft by 10-ft effluent conduit for this facility. A flushing system was installed since the facility was constructed; however, this system has not proved effective at removing the solids buildup.
- Provide flushing system in mixing chambers to flush accumulated solids from the floor.

14.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

New Effluent Conduit Flushing System (Project STA-FD-1). There are two alternatives for addressing the solids buildup in the effluent conduits and the chemical mixer chambers. These alternatives include:

- 1) **Alternative 1: Do Nothing/ Contractor Cleanout**
- 2) **Alternative 2: New Effluent Conduit Flushing System.** This alternative includes mounting a 6-in. HDPE flushing header along both sides of the effluent conduit approximately 2 ft above adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B, for Figure STA-FD-1-ALT-2 showing conceptual layouts. HDPE pipe is recommended for this application due to its corrosion resistance and its flexibility that imparts resistance to damage from impacts by heavy debris suspended in wet weather flows. The flushing header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 0.75-in.-diameter) that create a water jet aimed in a specific direction. The proposed hole spacing along the header will be approximately 18 to 24 in. A cursory analysis based on channel dimensions, slopes and anticipated grit sizes indicates that a minimum total flow rate of 3,500 gpm is required to adequately resuspend sediment from the floor of the square conduit and maintain adequate volume and velocity to carry the sediment to the terminus ends.

A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying.

Two new flushing pumps (approx. 5,200 gpm, 100 ft total dynamic head) will be installed at the end of the conduit and the existing flushing pumps removed. The pump size has been selected to provide a 1.5 safety factor on flushing anticipated grit volumes and particle sizes. The existing flushing system will also be removed. The new flushing pumps will be manifolded with a control valve to allow flushing of one-half of the conduit at a time. The existing flushing pump electrical system is assumed to have adequate load capacity for the new pumps; however, an allowance is included for rewiring and new conduits in the cost estimate. An allowance is also included for SCADA and PLC/human-machine interface programming.

Existing dewatering pumps may be overwhelmed by the large flushing flows generated by continuous post-event cleaning. The costs for this improvement include replacing the existing 100 gpm and 200 gpm dewatering pumps with larger pumps (1,000 gpm) and allowances for replacing some of the exposed discharge piping and valves. To avoid replacing the dewatering pumps, the flushing system could be operated in 15-minute intervals with adequate time between to drain the flushing water and sediment. Preliminary analysis indicates a total of 2 hours of flushing per pump unit should be considered as a starting point for operations. GLWA staff may increase or decrease the number of intervals over time as the effectiveness of the cleaning system is observed. The final designer should evaluate and refine the flushing volumes and generated header nozzle velocities using a sediment fate/transport model, CFD or lab scale model. Grit characterization is strongly recommended for proper sizing.

The likely flow management scenario assumed for construction will be to isolate the facility structurally or using existing controls. Seasonal restrictions are also assumed such that much of the work will take place in the dry season to minimize inundation risk during construction.

GLWA O&M staff also requested that a dedicated flushing system be provided for the two chemical mixing channels to flush accumulated solids from the floor after a storm event. A new flushing system

pipled from the existing NPW line in the “basin” area, extending down to the mixing chamber floors and drilled holes through HDPE pipe is recommended to address this issue. Figures (Figure STA-FD-1-ALT-2) that show the conceptual layout of this improvement are included in Volume 6 – Appendices, Appendix B.

The alternative evaluation for these alternatives is presented in Table 14-4. The sources of costs used in this evaluation are listed below:

- Contractor cleanout of this area is estimated to be \$400,000 every 5 years, based on costs at other screening and disinfection facilities. This O&M cost is annualized to \$80,000.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$90,000 for cleaning the influent channel prior to installing the flushing system. The \$140,000 equates to about \$400,000 after contingencies, and standard markups for design, construction assistance and contractor overhead and profit have been applied.
- The O&M costs for the current and proposed flushing system (Alternatives 1 and 2) are based on using Detroit River water, so there is no cost for water usage.
- Alternative 2 will provide the benefit of improved effluent water quality and hydraulic capacity because the conduit will be cleaned after every event. This will prevent the scouring of built up solids accumulation and will maintain hydraulic capacity of the effluent conduits.

This evaluation shows that Alternative 2 has the lowest NPV/Benefit cost and is the Best Value Alternative. Because of the improved health and safety, effluent water quality and hydraulic capacity, **Alternative 2 – New Effluent Conduit Flushing System is the recommended alternative.**

Table 14-4. Alternative Evaluation for New Effluent Conduit Flushing System (STA-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Contractor Clean-out	Health and Safety	2	2.10	\$ -	\$ 80,000	\$1,687,171	\$ 803,415	
	<i>Definition:</i>	Allow solids to build up and have a Contractor clean out the conduit, as needed	Water Quality & Compliance	2						
	<i>Adv.:</i>	No system to maintain	Capacity Enhancement	2						
	<i>Disadv.:</i>	Significant build-ups can impact facility hydraulic capacity. Cleaning effluent area is a high-risk activity, which requires significant GLWA coordination. Solids build-up may scour out of basin and negatively affect effluent water quality.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	New Effluent Conduit Flushing System	Health and Safety	5	4.18	\$ 2,472,000	\$ -	\$2,472,000	\$ 590,916	Best Value Alternative
	<i>Definition:</i>	Provide flushing system in effluent conduit using river water and provide a flushing system in the chemical mixing area.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Minimizes solids from being scoured from floor and affecting effluent water quality. No confined space entry to clean conduit.	Capacity Enhancement	4						
	<i>Disadv.:</i>	Increased maintenance of equipment.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.5 HVAC

14.2.5.1 Description of Existing System

The St. Aubin CSO facility consists of an underground headworks, chemical room, odor control area, supply fan room, control room, and utility support (electrical, emergency generator, and mechanical rooms) and a restroom. The facility has an offsite sample building. Table 14-5 provides a summary of the major equipment for the facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, and emergency shower/eye wash. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 14.2.10.

Table 14-5. Major HVAC Equipment at St. Aubin CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	SF-1	Supply Fan (Basin)	9,555 CFM
Chemical Room	HV-1	Heating Ventilating Unit (Mech Rm)	2,710 CFM
	EF-2	Exhaust Fan	3,010 CFM
Electrical Room	HV-2	Heating Ventilating Unit (Mech Rm)	4,665 CFM
	EF-3	Exhaust Fan (Odor Control Rm)	3,720 CFM

Table 14-6 provides a summary of the basis of design performance criteria for HVAC systems at St. Aubin and Table 14-7 provides the outdoor Basis of Design conditions.

Table 14-6. St. Aubin Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks	Class I, Div 1, Group D	N/A	N/A	12 ACH (Occupied)
Mechanical Spaces	Unclassified	60	96	Heat Relief
Office, Sampling Room, and Toilet Room	Unclassified	70	78 F Dry Bulb, 50% Relative Humidity	15 cfm per occupant
Odor Control Room	Unclassified for areas greater than 3 ft from odor control vessel. Class I, Div 2, Group D for areas closer than 3 ft.	60	96	6 ACH

Table 14-7. St. Aubin Original Outdoor Basis of Design Conditions

Outdoor Design Temperature		
Winter (Dry Bulb F)	Summer (Dry Bulb F)	Summer (Wet Bulb F)
3	91	73

report, they investigated the facility's current compliance with NFPA 820. Based on this evaluation, the following ventilation related deficiencies were noted:

- Air flow monitoring
- Horns and strobes
- Backup power supply for horns/strobes and flow monitoring

The Hazen report recommended these items should be included in the upcoming facility improvement project. Jacobs agrees with the proposed recommendations and would add that in addition to the Hazen recommendations, combustible gas detection and alarm of gas in excess of 10 percent of the lower explosion limit is also required by NFPA 820 in the Odor Control Area. These recommendation are being addressed in an upcoming project (CIP 260617).

14.2.5.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no HVAC-related issues that that would be classified as capital improvement “needs”.

14.2.6 Electrical

14.2.6.1 Description of Existing System

The St. Aubin electrical system consists of one DTE utility feed from a 480 V, 3-Phase outdoor transformer (secondary metering) and one generator feed from a 175 kW, 480 V, 3-Phase stationary diesel generator. The utility feed is connected to a 600 A motor control center (MCC-B) with a 200 A sub-feed connection to a 225A ATS. The ATS then feeds a distribution panel with one 200 A breaker and one 150 A breaker, which feeds two MCCs (MCC-A and MCC-C, respectively). The MCCs feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 14-8 provides a summary of the major electrical equipment for this facility.

Table 14-8. Major Electrical Equipment at St. Aubin

Location	Major Electrical Equipment	Description
Generator Room	Generator (Diesel)	175 kW, 480/277 V, 3-Phase
Electrical Room	MCC-A	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-B	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-C	600 A, 480/277 V, 3-Phase

14.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for less safe working conditions. These lighting needs are in addition to the recent LED lighting project. This issue is further described in the next section.

14.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project STA-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure STA-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin Interior – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the basin area to meet operational needs.
 - Outfall area – Add additional lighting at the facility's outfall.
 - Exterior power receptacles are needed on the wall of the facility near the basin to assist in the maintenance and operations of the facility.

The alternative evaluation is presented in Table 14-9. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$41,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 14-9. Alternative Evaluation for Electrical Improvements (Project STA-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 144,000	\$ -	\$ 144,000	\$ 41,143	Not Applicable
	<i>Definition:</i>	Add additional lighting in basin interior and outfall area.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.7 I&C

14.2.7.1 Description of Existing System

Control System: The original control system was installed in 1999 under PC-731. In 2002 the system was upgraded and interfaced into GLWA's overall SCADA Ovation control system. This upgrade provided the ability to remotely monitor the operations of the facility and the local collection system at SCC.

The existing control system contains an Allen Bradley-based PLC system consisting of an Allen Bradley redundant PLC-5 with local I/O controls that are installed in the facility's local control system panel. The operator workstation has a Rockwell RSView operating software platform and is located in the Control Room. The existing hardwired local backup control panel and other miscellaneous subsystems that are incorporated into the overall control system are outdated and need replacement. The control system network and switches are obsolete and do not meet GLWA SCADA Governance standards on redundant networks and switches stipulates and that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a backup radio system to communicate critical monitoring points back to the SCC on wide area network failure.

Flow and Level Sensors: Table 14-10 summarizes the level sensors and flow meters at the St. Aubin CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 14-10. Summary of Flow Meters and Level Sensors at St. Aubin CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent	1	Transit-Time (AccuSonic)
Effluent	1	Transit-Time (AccuSonic)
Toward Treatment Dewatering	1	Magnetic
CSO Level Sensors		
Dubois Diversion Chamber	1	Ultrasonic
Influent Channel	1	Ultrasonic
Mixing Chamber	1	Ultrasonic
Dewatering Chamber	1	Ultrasonic
Effluent Channel	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed	5	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic

14.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- The outfall level sensor level fluctuates significantly when the levels are high during discharge.

- GLWA staff note that local control of the equipment is needed, including dewatering pumps, flushing valve, and regulator gates) to improve maintenance. (It is noted that remote control of the regulator gates is included under the “Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities” project, so they are not further addressed in this report.)
- Process cameras are needed to observe process performance from the Control Room during a wet weather event
- The control system should be upgraded. GLWA is currently developing an RFP for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under “Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities.” The project will replace the existing PLC-5 control system and backup local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an ongoing project that has already been included in the CIP.
- The screen graphics are very difficult to understand and should be updated to match other facilities. This improvement is included in the Control System Improvements project described in the previous bullet.

14.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

I&C Improvements (Project STA-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the control system upgrade and simplifying the screen graphics, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements** including,

- Address outfall level sensor fluctuations
- Provide remote control of:
 - Flushing and dewatering pumps at outfall
 - Flushing valve for influent channel
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Address outfall level sensor fluctuations. During wet weather, the level sensor signal fluctuates. To remedy, it is recommended to ensure at least 18-in. are clear between the water surface and the level sensor element. Modify the installation, as necessary, to raise the level sensor element to be a minimum of 18 in. above the surface of the highest expected water level. This should be a maintenance issue that gets addressed before this I&C project; however, it is included as a capital improvement in case it is not completed before this project.

Provide remote control of flushing and dewatering pumps at outfall and flushing valve for influent channel. Outfall Flushing and Dewatering Pumps: Provide remote control of the Flushing and Dewatering Pumps at the outfall from the CSO facility. The recommendation is to install a dedicated fiber optic cable from the CSO facility to a control panel located at the outfall.

Influent Channel Flushing Valve: It is recommended to provide remote control of the influent channel flushing valve to allow operations more flexibility when operating the facility during CSO events.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 14-11. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.5 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and improved O&M. The NPV/Benefit cost for Alternative 2 is \$67,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved control and maintainability associated with the I&C improvements, Alternative 2 is the recommended alternative.**

Table 14-11. Alternative Evaluation for I&C Improvements (Project STA-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Someone needs to be in Control Room to operate pump remotely during maintenance.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 170,000	\$ 2,500	\$ 222,724	\$ 67,153	Not Applicable
	<i>Definition:</i>	Add local control to pumps and valves; add process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved ease of maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased instrumentation to maintain.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.8 Site

14.2.8.1 Description of Existing Site

The St. Aubin facility was constructed in 1999. Access to the site is off of Atwater Street. The access entrance gate is a 25-ft wide sliding vehicular gate. Site security is provided by a 6-ft high security fence around the perimeter of the site. The parking lot consists of 8-in. reinforced concrete pavement with 8-in. crushed limestone base. Concrete sidewalk widths vary from 5 to 14 ft and are approximately 4 in. thick.

The St. Aubin outfall site includes the Sampling Building and access hatch opening to the outfall conduit. The Sampling Building and outfall discharge site are secured by cyclone fencing on all four sides of the site. A 12-ft cantilever sliding gate is located on the west fence line to provide access to the secured area. The secured outfall site is located approximately 340 ft off Atwater Street. A gravel drive extends from Atwater Street to the entrance gate.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

14.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- There are several site issues at the St. Aubin outfall site including: 1) poor drainage in the access drive area between Atwater St. and the fenced area; 2) fencing in disrepair; 3) difficulty in removing hatch plates; and 4) access to the backwater gates. The poor drainage of the access drive has damaged the road surface and has created issues with accessibility to the secured area.
- The concrete surface at the northwest corner of the St. Aubin CSO facility has cracked due to settlement, causing runoff to flow back toward the building.
- At the St. Aubin CSO Control and Headworks Building, are stored in the Odor Control Room or outdoors. There is insufficient space inside the existing building to efficiently store all of the O&M equipment, as well as the equipment to maintain the site, in the main building. A storage building is needed to protect this equipment from ultraviolet light degradation and the elements. This building is currently planned to be installed under a separate project (CIP 260617).
- There are cracks in the sidewalks on the south and east sides of the Control Building.

14.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Outfall Site Improvements (Project STA-Site-1). There are two alternatives to address the issues identified at the St. Aubin outfall:

- 1) **Alternative 1: Do Nothing**
- 2) **Alternative 2: Outfall Site Improvements**

At the outfall site area, which is approximately 340 ft by 75 ft, regrading of the site is included in this alternative to direct the drainage north to the exiting channel to help alleviate poor drainage in this area. Additionally, the gravel drive in this area could be replaced with an alternative design featuring a grass paver surface supported on a new engineered support base. The grass pavers could be for the full width of the access drive, replacing the existing gravel drive. This will also complement the Detroit Riverwalk area in the vicinity. Figure STA-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the location of these issues and suggested improvements.

The cyclone fencing around the site is in disrepair. The fencing includes approximately 400 ft of 8-ft-tall cyclone fencing. The fencing should be replaced to maintain security. Since the facility is located in a city park in a high visibility location, it is suggested that the cyclone fencing on the west, east and south sides of the site be replaced with ornamental fencing. The existing 12-ft wide automatic cantilever sliding gate has experienced numerous recent breakdowns. This equipment has likely reached the end of its useful service life and should be replaced.

The hatch openings over the two outfall backwater gates have dimensions of 8 ft by 10.5 ft. The openings over the two stop log guides are 10.25 ft by 3 ft. The hatch plates over the outfall gate openings are 0.5-in. thick stainless steel plates. These cover plates are very cumbersome to remove due to their weight. It is suggested that the outfall cover plate design be changed to a lighter weight cover plate. The cover plates over the stop log gates are Bilco style hatch covers – these gates should be considered for replacement due to their age.

Accessing the outfall backwater gates and stop logs within the secured fence line can be difficult as the area is all grass surface. It is suggested that the grass paver system identified for the entrance access road to the site be extended within the site so that trucks and equipment can access the outfall structure and gate and stop log hatch openings.

The minor repair to the concrete surface at the facility is included in this project. It is suggested that that this portion of the slab be removed, the subsurface regraded, and the concrete slab replaced to provide proper drainage away from the building.

The alternative evaluation is presented in Table 14-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the added features are assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. **However, because of the improved accessibility, security and maintenance with the Outfall Site Improvements, Alternative 2 is the recommended alternative.**

Table 14-12. Alternative Evaluation for Outfall Site Improvements (Project STA-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lowest cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Site issues remain a concern.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2

	<i>Comments:</i>	None	O&M Ease	4						

14.2.9 Architectural

14.2.9.1 Description of Existing Facilities

The St. Aubin CSO facility consists of chemical room, utility support (electrical, emergency generator and mechanical), control room, odor control room and miscellaneous other rooms. The facility has an separate sample building at the end of the outfall.

14.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering system
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that that additional storage is desired at the St. Aubin facility. Since the meeting, the GLWA Program Management team generated a proposal for a new storage building to be located along the west side of the building, near the existing electrical room. This building is intended to be added during the upcoming capital improvement project (CIP 260617).

14.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (STA-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) Alternative 1: Do Nothing.

2) Alternative 2: Architectural Rehabilitation. Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation include the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints
- Remove and replace isolation/ cove joint sealant and around building perimeter

- Remove failed concrete floor coating, clean floor, and reseal floor with chemical resistant coating
- Remove corrosion at bottom of man door and coat steel framing

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure STA-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 14-13. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 14-13. Alternative Evaluation for Architectural Rehabilitation (Project STA-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 136,000	\$ -	\$ 136,000	\$ 43,871	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

14.2.10 Safety

14.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

14.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 14-14. The capital improvement project to address these issues is included in the table.

Table 14-14. Identification of Capital Improvements for Safety Issues

Location	Description	Proposed Corrective Action	Capital Improvement Project
Basin	Seal-off fittings for mixer electrical feed is bypassed (typical of some other mixers also) and open junction box	Incorporate seal-off fitting into electrical wiring.	I&C Improvements
Dewatering Chamber	Exposed power wires in junction box and bypass of explosion-proof seal-off fitting in dewatering pump chamber	Enclose junction box and incorporate seal-off fitting into electrical wiring.	I&C Improvements
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project STA-SAFE-1)

14.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project STA-SAFE-1). This project should address the safety issues identified above. These issues include:

- Fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 14-15 shows the one alternative.

Table 14-15. Alternative Evaluation for Safety Improvements (Project STA-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 79,000	\$ -	\$ 79,000	\$ 20,881	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at St. Aubin CSO Facility.

14.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the St. Aubin CSO facility, Table 14-16 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 14-16, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 14-16. Listing of Asset Condition Assessments for St. Aubin Facility

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The fire suppression system was assessed independently by Simplex Grinnell and not included in the ACES report.

^c The one gas detector is a portable unit and was not assessed.

^d The one pump not assessed was the Disinfection Sample Pump No. 2, which was inactive.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the St. Aubin Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

14.3 Capital Planning for St. Aubin CSO Facility

14.3.1 Summary of Capital Improvement Plan Projects

Table 14-17 provides a summary of the recommended CIP projects and associated capital costs for the St. Aubin CSO facility based on the alternative evaluations conducted for this facility.

Table 14-17. Summary of Recommended Projects at St. Aubin CSO Facility

Project No.	Alternative	Description	Total Project Cost
STA-FD-1	2	New Effluent Conduit Flushing System	\$ 2,472,000
STA-ELEC-1	2	Electrical Improvements	\$ 144,000
STA-I&C-1	2	I&C Improvements	\$ 170,000
STA-I&C-2	1	Control System Upgrade	Ongoing Project
STA-SITE-1	2	Outfall Site Improvements	\$ 806,000
STA-ARCH-1	2	Architectural Rehabilitation	\$ 136,000
STA-SAFE-1	1	Safety Improvements	\$ 79,000

14.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 14-18. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 14-18. Capital Improvement Plan Projects for St. Aubin CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
STA-1 Flushing System Improvements	\$ 2,472,000	2028 <i>Timing based on need to clean effluent channel in 10 years from last cleaning in</i>	STA-FD-1	New Effluent Conduit Flushing System	\$2,472,000
STA-2 Facility-Wide Electrical and I&C Improvements	\$ 314,000	2035 <i>Timing based on best judgement</i>	STA-ELEC-1	Electrical Improvements	\$144,000
			STA-I&C-1	I&C Improvements	\$170,000
STA-3 Outfall Site Improvements	\$ 806,000	2028 <i>Timing based on best judgement</i>	STA-SITE-1	Outfall Site Improvements	\$806,000
STA-4 Facility-Wide Safety and Architectural Improvements	\$ 215,000	2023 <i>Project should be initiated as soon as possible</i>	STA-ARCH-1	Architectural Rehabilitation	\$136,000
			STA-SAFE-1	Safety Improvements	\$79,000

Unlike the other sections, there are no existing assets in the projects listed above. As such, the Asset Information tables shown for the other facilities are not included here.

14.3.3 20-Year Capital Outlay Plan

Table 14-19 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 14-19. 20-Year Capital Outlay Plan for St. Aubin CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 113,300	\$ 23,500	\$ -	\$ 48,800	\$ -	\$ 22,300	\$ -	\$ 4,200	\$ -	\$ -	\$ 14,500	\$ -	\$ -

2027	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2028	\$ 202,929	\$ 30,747	\$ -	\$ -	\$ 172,182	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2029	\$ 1,831,486	\$ 7,714	\$ -	\$ 38,571	\$ 15,428	\$ -	\$ -	\$ -	\$ -	\$ 1,769,773	\$ -	\$ -	\$ -
2030	\$ 524,523	\$ 2,610	\$ -	\$ -	\$ 472,328	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 49,585	\$ -	\$ -
2031	\$ 332,485	\$ -	\$ -	\$ 292,302	\$ 40,183	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2032	\$ 8,429	\$ 8,429	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2033	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2034	\$ 842,645	\$ -	\$ -	\$ 632,938	\$ -	\$ 65,056	\$ -	\$ 144,651	\$ -	\$ -	\$ -	\$ -	\$ -
2035	\$ 425,483	\$ -	\$ -	\$ 328,988	\$ 45,226	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 51,269	\$ -	\$ -
2036	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2037	\$ 508,199	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 508,199	\$ -	\$ -	\$ -	\$ -
2038	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2039	\$ 409,967	\$ 74,025	\$ -	\$ -	\$ -	\$ 150,325	\$ 40,007	\$ 95,847	\$ 49,762	\$ -	\$ -	\$ -	\$ -
2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 5,402,905	\$ 147,025	\$ -	\$ 1,517,743	\$ 745,348	\$ 237,681	\$ 40,007	\$ 244,698	\$ 564,265	\$ 1,769,773	\$ 115,354	\$ -	\$ 21,012

- Notes:
- Explanation of large capital outlays in first two years:
- Retention System: St. Aubin “basin” (\$176,000) received a score of 5 based on the NTH structural assessment. One magnetic flow meter (FM-2; 49,000) received a score of 5 because the meter was not functioning properly based on SCADA data review in early 2020.

Appendix F

Project Risk Register

PROJECT RISK REGISTER

Updated: 7/17/23

Project No.: 276260
Project Name: OAKWOOD AND LEIB CSO FACILITIES IMPROVEMENTS
Client: GREAT LAKES WATER AUTHORITY (GLWA)
Project Manager: Ali Khraizat
Project Technical Lead: Steve Fehniger

Identification					Risk Response Planning
Risk ID	Activity	Risk Category	Risk Description	Cause of Risk	Risk Response
6	CFD modeling will require time for troubleshooting if we have issues with solution convergence and to understand/explain why the results are different than expected.	CFD Modeling	The time it takes to resolve solution convergence issues impacts our ability to complete the required CFD modeling and design for the Leib Facility.	CFD modeling results in solution convergence issues and results that are different than expected or not within acceptable tolerances.	CFD Model Task Lead (Carrie Knatz) must stay in close communication with CSL/PM (Ali Khraizat) and PTL (Steve Fehniger) on the status of the CFD modeling and whether she is having issues with solution convergence that may adversely impact our ability to meet the design milestones.
12	We must have a proactive conversation with GLWA to establish agreement on the CFD model boundary conditions (or limits) since it was not clearly stated in the contract terms.	CFD Modeling	GLWA does not accept our CFD model boundary condition assumptions from which our current budget was developed. CFD modeling recommendations are unable to be defended with EGLE.	GLWA is unwilling to accept the CFD model boundary conditions since it was not explicitly stated in the contract.	Conduct interim CFD model meetings, review, discuss and justify the model boundaries as a team to confirm compliance with the overall project goals.
7	Update and share a frozen (key) decision list or action item list with GLWA’s PM to prevent circle back on decisions.	Change Management	Project team must redo work and/or frustrated client and potential impact to overall schedule	Concise direction not achieved and/or priorities/preferences shifted	Thoroughly document and review client directives and decisions and internal directives and decisions during design review meetings. Develop key decision summary logs to help guide the process moving forward.
5	Engage the appropriate GLWA staff and stakeholders (management, operations and maintenance personnel) at the right times during the entire process from conceptual design through start-up and commissioning such that they are integral team members that can make quick, decisive decisions and that they are comfortable with the intended operation of the facilities.	Communications	Key GLWA stakeholders do not attend meetings or workshops where their attendance is required. Receiving GLWA's input from a single unified voice (versus conflicting feedback and opinions) when it is required and not beyond due dates.	A "Core GLWA Team" is not identified early to this project and departments within GLWA that must interact with the CDM Smith project team for this project to be successful (management, engineering, operations and maintenance personnel).	The CDM Smith team will bring this risk to the attention of GLWA at meeting and explain to GLWA the importance and need to identify a “Core GLWA Team” (management, engineering, operations and maintenance personnel) that can make decisive decisions on the project (from conceptual design through start-up, commissioning and operations) and confirm this GLWA team's commitment to attend all required meetings/workshops/ride alongs.
17	Realize the scope of work of other construction projects (ongoing or future)	Construction	The team has limited knowledge of the scope of work of other projects at Leib and Oakwood.	Design decisions and improvements are based on an incomplete or inaccurate understanding of other projects which may interrupt the construction schedule.	Continued cooperation and coordination meetings with the other project teams. Obtain information regarding completed projects, awaiting construction at the time of this project's improvements (Upstream Junction Chamber at OKW) from GLWA.
18	Understanding of the timing long lead items	Construction and Schedule	Major pieces of equipment requiring longer lead times than originally expect could impact the overall construction schedule	Lack of understanding of the long lead items and/or inaccurate actual lead times associated with them.	The design team to follow-up with local vendors and/or manufacturers for updated lead times throughout the design project lifecycle. Consider addition of scheduled float to address longer lead times.
1	Prevent project "circle back" on design decisions, especially during the detailed design phase. - CSF #9	Design Process	Project team must redo work and make modifications to the design multiple times.	Stakeholders do not provide clear direction or makes changes in their priorities and/or preferences previously agreed upon without considering how these changes may impact the overall project.	The design team will maintain a "frozen" items list (Key Decisions List) and review this list with the client at monthly design review meetings and discuss the impact to the project schedule and/or budget. Should the client decide to change their direction, the design team will assess the impact to schedule and budget and discuss with GLWA to explain the impacts to the project.
4	Resolve the Leib screening issue.	Design Process	The CDM Smith design recommended solution does not resolve the Leib screening issues of blinded screens and screenings blowby.	Team is not able to discern the root causes of the problematic equipment, process and/or activity.	The CDM Smith team will come to fully understand the current situation and the limitations and capabilities of the current equipment and will engage GLWA on their desired outcomes and develop alternatives for improvement that achieves those desired outcomes in coordination with the screen manufacturer.

Identification					Risk Response Planning
Risk ID	Activity	Risk Category	Risk Description	Cause of Risk	Risk Response
8	Develop solutions that address the root cause of the problematic equipment, process and/or activities by studying, using and leveraging previous studies and past evaluations and by conducting objective root cause evaluations.	Design Process	Alternative solutions do not address the root cause of the problematic equipment, process and/or activity.	Team is not able to discern the root causes of the problematic equipment, process and/or activity.	CDM Smith PM will clearly communicate to each of the Task Leads the criticality and importance of developing solutions that address the root cause of the problematic equipment, process and/or activities. A list (overall summary) for each facility (including equipment, processes and activities) of what data we have and what we still might need and whether what we have is sufficient to proceed with design. This individual must engage the appropriate GLWA staff to obtain all studies and evaluations that have been conducted by others at each facility and provide CDM Smith access to them.
9	Improve reliability, flexibility, operability, safety, and reduce maintenance by improving operational and maintenance efficiencies while facilitating system readiness for increases to influent flow rate within the discharge permit limits.	Design Process	Final facilities design fails to satisfy GLWA's criteria of improved operational and maintenance efficiency (i.e. reduced maintenance), reliability, flexibility and safety during increases to influent flow rate while meeting discharge permit limits.	The project team is over confident and/or faulty in their analysis and belief that the design alternatives considered and recommended improve reliability, flexibility, operability, safety, etc.	When identifying the various design options for alternatives analysis, the design team must clearly articulate and receive acceptance from GLWA on how each design alternative will be evaluated against it ability to improve reliability, flexibility, operability, safety, and reduce maintenance by improving operational and maintenance efficiencies and facilitating system readiness for increases to influent flow rate within the discharge permit limits.
10	Prepare and update auxiliary systems/facilities and properly design the mechanical equipment needs to accommodate future demands and additional loads (coming after inter-sewer connections are made) to minimize the potential for system interruptions and high hydraulic grade lines in the collection system by establishing early on what the future flow rates/loads are going to be with GLWA.	Design Process	Final facilities design fails to accommodate future flow rates and additional loads.	Inaccurate future flow rate/load data or the project team is over confident and/or faulty in our analysis and belief that our designs can properly accommodate these future flow rates/loads.	A dedicated conversation(s)/TM/Workshop with GLWA to establish what is the appropriate design criteria be used regarding future flow rates/loads and when we need to have a final decision on this information so as to not adversely impact the baseline project schedule. PM should document these conversations in writing and obtain GLWA's acknowledgement of the decisions that are made. Using this information, the design team must confirm that the design to address the mechanical equipment needs and the design updates to the auxiliary systems/facilities can properly accommodate these future flow rates/loads.
15	Identify a means to provide sufficient mixing performance with reduced maintenance costs (e.g., reduced number of induction mixers) at Baby Creek, Connor Creek and Leib facilities.	Design Process	Final facilities design fails to provide sufficient mixing performance with reduced maintenance costs (e.g., reduced number of induction mixers) at Baby Creek, Connor Creek and Leib facilities.	The project team is over confident and/or faulty in their analysis and belief that our recommendations will provide sufficient mixing performance.	CFD Modeling Task Lead must establish the following necessary information on the existing systems: 1) As-built drawings of Baby Creek, Connor Creek and Leib facilities including mixer locations; 2) Existing mixer data sheets including flow and geometry information; and 3) Available head loss for retrofit configurations. Both CFD and Disinfection task leads, must develop what is needed for "sufficient" mixing means.
3	Design improvements must account for the integration of construction activities and maintenance of facility operations during construction for a seamless transition and to minimize or eliminate shutdowns during construction.	MOPO	Facilities and/or process areas are unexpectedly shut down due to site activities without any contingency plan.	The MOPO Construction Sequencing Plan/Specification and/or the Critical Path Method Construction schedule is poorly prepared and does not work properly when followed and implemented. Constructability analysis is incomplete or not thorough enough to identify all constructability issues.	MOPO specifications and workshops are programmed into the scope at 30% and 60% but to further mitigate this risk, CDM Smith project management team will work with the Task Leads to verify that these specifications and workshops progress with design definition and sequence of construction and to engage EGLE as needed for part 41 permit requirements.
16	Provide effective means to operate the CSO's during disinfection upgrades, pump rehab and screen replacement.	MOPO	CSO Treatment Facilities will not be able to meet/exceed permit compliance during construction during a wet weather event.	The temporary operational recommendations are not followed or don't address operational needs during equipment replacement.	The design team must determine which team members are vital to developing the temporary operational strategies required to maintain plant operations. These recommendations must be reviewed and agreed upon by GLWA. Update SOPs per outage impact results.
2	The newly constructed facility must operate reliably "on demand" without a complicated process (keep it simple).	O&M	Our design includes a complicated process that does not allow the facility to operate reliably "on demand" per the client's definition and expectations.	CDM Smith design team does not obtain clear insights from GLWA with regards to the definition of a simple vs. a complicated process.	This was identified as Risk #5 during the client project kickoff meeting. To mitigate this risk, it was agreed that will incorporate and communicate this premise at the internal Guiding Principles Decision Making meeting and Task Leaders to lay out all principles and precepts that will guide the design team throughout the project. Review the design with client at 30% with a focus on identification of improvements or controls for improvements that are deemed too complicated.

Appendix G

Comment Resolution Log

GLWA Contract - 2101475
CSO Facilities Improvements Project
Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
1	1	1,1	Nastally	How come the ASI memo covers baby and conner creek, but this TM does not?	Project needs required the creation of detailed hydraulic models for the Leib SDF and the Oakwood CSO PS & RTB. Detailed hydraulic models were not prepared at Baby Creek and Conner Creek.	No
2	1	8, Table 3-2	Nastally	This includes the NWI diversion?	Yes. Better clarification of future flow rate conditions identified in the Table 3-2.	Yes
3	1	9, bullet 1	Nastally	Is this right? We don't consider one channel out of service for firm capacity?	For existing conditions, the facility was modeled with all screen in-service to align with the original design assumptions. An existing conditions scenario was created with one channel out-of-service to evaluate the firm capacity.	Yes
4	1	9, bullet 2	Nastally	Wouldn't this condition result in additional blinding above manufacturers information because there is no sideflow being generated?	This condition was reviewed hydraulically to provide a consistent hydraulic condition for each scenario reviewed. Actual operations will be coordinated with the screen design. The headlosses through the screen are based off of an assumed blinding factor and a flow rate.	No
5	1	9, 4.2 bullet 1	Nastally	Why not also modeling 4 channels of ROMAG screens, per earlier discussions?	TM-1 updated to include model scenario with 4 channels of ROMAG screens.	Yes
6	1	9, 4.2 bullet 1	Nastally	What also about 4 channels of duperon? I would think we need to model these 3 situations regardless. The last one assumes the cost of retrofitting w/ dupérons is acceptable to GLWA for 1, and then ultimately 3 more.	The hydraulic analysis initially focused on the leading alternative for the screen replacement in one screen channel with multi-rake screen (pilot). This was followed by a hydraulic analysis of the GLWA preferred alternative of all-Romag screens to determine technical feasibility from a hydraulic perspective. Feasibility was confirmed given the maximum HGL in influent channel was lower than the existing conditions maximum HGL in the influent channel.	No
7	1	9, 4.2, para 4	Nastally	See comment above	The hydraulic modeling scenarios were aligned to the screening alternative analysis. Additional hydraulic scenarios can be added once the recommended screen arrangement is selected.	No

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
8	1	10,2	Nastally	What memo will this be in, and how will we tie back to here?	The proposed conditions alternatives are considered hydraulically acceptable if the proposed conditions gradeline is below the existing conditions gradeline at the upstream end of the facility. The study phase hydraulics have found the proposed conditions hydraulic gradeline to be below the existing conditions gradeline which does not warrant additional analysis. This check will be completed at major milestones throughout the design phase of the project to confirm the hydraulics are acceptable.	No
9	1	11,3	Nastally	See comments above on other "proposed" conditions.	Better clarification of current and future flow rate conditions identified in Table 3-2.	Yes
10	1	12,1	Nastally	See comment on Leib for closed TTS and closed Screenings gate	This condition was reviewed hydraulically to provide a consistent hydraulic condition for each scenario reviewed. Actual operations will be coordinated with the screen design.	No
11	1	12,3	Nastally	So this needs to be updated based on other scenarios. It's difficult for GLWA to make a decision with only limited information.	Hydraulic analysis was updated to include the evaluation of the all Romag alternative.	Yes
12	1	Appendix A, 16(3), Notes	Nastally	It was designed to several river levels from what I can tell. The main difference is the higher the river, the less throughput.	Statement made in TM reflects what is found in the BOD report for these facilities.	Yes
13	1	Appendix B, 19(2), Data Sheet Sample	Nastally	How much of their headloss is based on sideflow. I recall this being discussed of 10% of the total flow going over the weir, but the way it was modeled (100%) wouldn't yield the proper results, right?	Manufacturer's data was provided based on a given throughput of the screen and a given blinding percentage. The hydraulic model was set up to determine the HGL for the given condition.	No
14	1	Appendix C, 25, HGL matrix	Nastally	Is this w/NWI or without?	Better clarification of current and future flow rate conditions identified in Table 3-2.	Yes
15	2	2,2	Nastally	inserted "as"	"as" inserted as indicated.	Yes

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
16	2	3,4	Nastally	See email I sent to Ali on this...the operations team is now (after 3 years) indicating that it is causing problems, but for 3 years there were none. I still wonder what's going on and asked CDM to look into and perhaps this would be additional costs.	CDM Smith has completed a review of pump condition reports (4) from Kennedy Industries and coverage of the system curve envelope operationally (See TM-15) as well as operational practices. Suggest discuss findings in a future meeting.	No
17	2	3,4	Worth	Has it been determined if this is a clogging screen issue or a flushing system issue, or both?	This has been determined to be a sanitary influent channel screen blinding/clogging issue (screens manually cleaned). CDM Smith does not anticipate the flushing system in storm wet well caused screen issues as it is not frequently utilized based on discussions with operations staff.	No
18	2	4,1	Worth	Pullman is going to remove less than 150 tons from the wet wells. Compared to other facilities, quantity was not overwhelming and it was a relatively quick process once flows were managed and air flow was established into the wet wells	Noted, favorable that not much material removed comparatively. Photos noted some pump bells nearly surrounded in debris which would impact performance. As discussed in TM workshop No. 2, we plan to discuss lessons learned from the OKW wet well cleaning with Pullman and their cleaning sub.	No
19	2	4,5	Nastally	I'm not sure I follow this. If we turn on storm pumps, it's going to the RTB, and so why wouldn't the number be the same? Or clarify that 25 times a year means high wet well, but no storm pumps turn on. To me if that is the case here, it wouldn't be "operates about 25 times per year" then.	TM description clarified to reflect 25 time a year at least one storm pump turns on. The activation of the RTB is linked to discharge to the river which historically has happened far less than frequency of pump starts.	Yes
20	2	5,4	Nastally	Added "the"	"the" added where indicated.	Yes
21	2	6,1	Nastally	Replaced "if" with "whether a"	Replaced "if" with "whether a" where indicated.	Yes
22	2	7, bullet 2	Worth	Are these in use? If not, why clean them?	Yes, the approach tunnels and integral sanitary trenches are in use, will be part of the list of areas to be cleaned as part of the construction contract.	No
23	2	7, bullet 3	Worth	Has this been discussed with Pullman? Cleaning was straight forward, except for the sanitary wet well which is proving difficult to access	This discussion has been added to the Next Steps section to be conducted in the BOD phase.	Yes

Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
24	2	8,3	Nastally	We agree	Noted. Based on discussion at TM Workshop No. 2 we plan to identify that the contractor will be able to discharge decant water to MH along sanitary system but not use the sanitary pumps.	Yes
25	2	8,4	Nastally	It needs to be vac'd out and hauled off.	Noted.	Yes
26	2	8,5	Nastally	Now that I type this, I wonder if the previous cleaning efforts are slurring up the sludge and using our pumps and thus after 3 years of removing the bar racks we are experiencing issues (not because of screenings, but because of heavy grit being sent to them). Please confirm if this is your understanding	As briefly discussed at the TM workshop CDM Smith noted the use of sanitary pumps during cleaning process could be a contributor but not likely the primary cause of sanitary pump issues. As noted in comment 16, plan to discuss further with GLWA.	No
27	2	8,5	Worth	Review process with Pullman. Vac'd out, decanted, landfilled.	The potential methods and constraints will be defined in a cleaning specification. The TM updated to reflect a meeting with Pullman to be conducted in the BOD Phase (Next Steps section).	Yes
28	2	10,1	Nastally	What about a "dingo" (like a skid steer, but smaller).	As discussed in the TM workshop CDM Smith does not recommend equipment due to limited maneuverability space and risk to damage pump if impacted by the equipment. In addition, recent Pullman cleaning procedures did not include equipment such as a dingo.	No
29	2	16, table 3-2	Nastally	I'd be curious what Tom Hall thinks, but I think Option 1 is the best.	As discussed in TM workshop, CDM Smith discussed with Tom Hall and confirmed his strong preference for Option 1 (dedicated grease lube system).	Yes
30	2	16, 4	Nastally	See my comment above	See response immediately above.	Yes
31	2	17,1	Nastally	This area doesn't need to be for storage	Noted. No longer avoiding the motor room for grease lube system equipment based on input at 2/13/2023 workshop as summarized in TM that no need to maintain storage function.	No
32	2	17,1	Nastally	I think it makes most sense here	Noted.	Yes
33	2	17,1	Worth	Will this part of the reality capture?	Yes, the new equipment will be included in the 3D model as part of the 30% drawing preparation thereby resulting in capture in the virtual reality capture.	No
34	2	18,2	Nastally	Added "as the design progresses"	Added "as the design progresses" where indicated.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
35	2	19,3	Nastally	If it's manual today and we make it automated, and it's pennies...it makes sense to me to do so	Understood, planning to include in the design of the lubrication system.	Yes, below Table 3-4
36	2	19,5	Nastally	We agree	Noted.	Yes
37	2	21, bullet 1	Nastally	Add period at end of bullet	Period added.	Yes
38	2	21, bullet 5	Nastally	No doubt about it.	Noted.	No
39	2	22, bullet 1	Nastally	Does this even include treatment costs? Or is this just GLWA direct costs we pay to Detroit for our water bill?	This is only the direct cost on water bill which includes the clean water cost and the cost for treatment of an equivalent quantity of wastewater even if not directed to collection system as indicated in TM "combined water and sewer charges".	No
40	2	22, bullet 4	Nastally	Add "are"	"are" added where indicated.	Yes
41	2	22,2	Nastally	Also we should take GLWA's procurement into account. Given our procurement is almost a 1 year long process, we need to be sure it makes sense. So if the full design was only 6 months behind, it probably doesn't make sense to separate them because the net effect is 6 months time savings.	Noted, procurement process is included at about 13 months. The analysis with associated assumptions showed less than 6 months time savings.	No
42	2	22, bullet 5	Nastally	This will need to be updated	Updated.	Yes
43	2	22, bullet 5	Worth	This should be verified as part of Task B	This was clarified to be a basis for comparison of a stand alone contract but will be further reviewed as the design progresses.	Yes
44	2	23, bullet 1	Nastally	How long is this compared with getting everything else done?	The separate contract schedule was compared to the current construction schedule in TM workshop demonstrating a time savings of approximately 3 months inclusive of associated assumptions.	Yes
45	2	23, bullet 1	Nastally	See above	See responses above.	No
46	2	23, bullet 1	Nastally	Is this inclusive of bid phase? If so, I think we're close here with actual time in procurement.	No, bid phase is separate. The comparison of 1 year to the 1 year + 1 month was discussed at the TM workshop.	No

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
47	2	24, 1	Worth	My thinking is that this makes sense only if there is a demonstrated advantage to starting early, the longer duration can be managed in the contract. Interim milestones, special provisions for releasing retention, there are coordination advantages and potential savings from already engaging all the same players under the main contract.	As discussed at the TM workshop not a significant time savings based on analysis and assumptions.	No
48	2	25,1	Nastally	Is there a risk of this "sump pump" failing and we flood out the intermediate level?	Discussed in the TM workshop and concluded an additional sump pump will be required either in the sump (if will fit) or on floor beside the sump pit.	Yes
49	2	25,1	Nastally	Inserted text "a"	Inserted "a" where indicated.	Yes
50	2	26,2	Nastally	I assume CDM is performing this confirmation? I thought we had discussed CDM providing us with some sketches and part numbers and we'd install. What is the status of that?	CDM Smith team selected an instrument and provided guidance to GLWA for temporary monitoring of OKW secondary water near Storm Pump 7. Results of monitoring will be reviewed when installed and operated for sufficient duration leading to recommendation in preliminary design if monitoring period completed in that phase.	No
51	2	27,5	Nastally	See my questions above	See responses above.	No
52	3	6,1	Nastally	Remove Not used. section	Removed section and renumbered subsequent sections.	Yes
53	4	2,1	Nastally	Text added- in subsequent storm events	"in subsequent storm events" added where indicated.	Yes

GLWA Contract - 2101475

Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
54	4	10,1	Nastally	But this would likely change with NWI diversion, I assume. Also - based on the next paragraph, if we had 6 or 7 storm pumps running, the amount of debris on the screens would increase 6 or 7 fold I presume. The screen wash waster then could have a different impact when there are 6-7x more screenings.	Noted and agree that more screenings are anticipated when NWI is connected. Amount removed per screen may not increase as much as the total amount of screenings increase, based on observation that most screenings are removed by the screen closest to the operating pump discharge and the screen(s) farther from the operating pump have fewer screenings. Screenings capture estimates from WWMP were 1-3 cf/MG for 6mm screens. The 3 cf/MG equals 134 cf/h at OKW capacity of 1660 cfs (<150 cf/h, capacity of screenings grinder) Description of estimated screenings removal with additional flow based on WWMP estimates has been added as new Section 3.5. See related comment 59.	Yes
55	4	10,1	Worth	Whats the confidence level that this is typical based on fluctuations throughout the year?	At the end of paragraph 2 on page 10 there is a reference to seasonal variability in the screenings collected, based on operator interviews.	No
56	4	10,2	Nastally	"if" replaced with "during"	"if" replaced with "during" where indicated.	Yes
57	4	13,1	Nastally	I don't recall "horizontal". 11-1/4 degree incline is what I recall.	As noted in the TM text, "horizontal" was stated in the CS-299 report. The JWC field report did recommend an 11 degree elbow. The modification in place is effectively horizontal. The performance of existing configuration is what is important to the current evaluation.	No
58	4	15,5	Nastally	The real test is when the diversion is completed (if ever).	Noted. These evaluations were conceptual. We are not recommending reducing the washwater volume by pressure reduction or nozzle replacement, due to importance of screen cleaning and preventing screens from entering the basin for permit compliance.	No
59	4	17, bullet 10	Nastally	I didn't see the purpose of this in our meeting in February.	We needed to consider it for the alternatives evaluation. Refer to first full paragraph on next page (starts with words "The existing grinder capacity..")	No

Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
60	4	17,2	Nastally	But how will it change with the NWI diversion?	We don't know for sure, but anticipate debris will be similar to what currently arriving at Oakwood and PS-2. For items to get to the grinder they have to be lifted by the storm pumps and the screens and be able to be conveyed to the grinder. See related response to comment #53. An estimate of screenings removal and collection after additional flow routed to Oakwood was added to the TM. Discussion of additional screenings collected in the dumpster was added to the recommendations section based on feedback received at the workshop on 4/19/23.	Yes
61	4	27, Table 5-4 col 1	Nastally	think we stick with what we have.	Noted. This is the recommended alternative.	No
62	4	27, Table 5-4, col 3	Nastally	We've done almost nothing since 2012	Understood. We expect the hours of runtime to increase with the equipment online for most events since the discharge chute modification and increased runtime hours after connection of NWI.	No
63	5	2, Table ES-1	Nastally	How has EGLE responded since this newly calculated flow essentially derates the facility.	The new Leib peak flow after Meldrum sewer connection (950 cfs) were presented and discussed with EGLE on 2/7/23. No comment or objection is received about it.	No
64	5	2,1	Nastally	Deleted ", "	Comma deleted.	Yes
65	5	2,bullet 1	Nastally	Renovate, or replace? They're ~ 20 years old.	Replace	Yes
66	5	2, bullet 2	Nastally	Added text "(aka side flow)"	"(aka side flow)" added where indicated	Yes
67	5	3, last para	Nastally	Deleted space	Extra space deleted	Yes
68	5	4,2		I think CDM smith needs to figure out how to test this today...so we can verify. \$1.8 Million (I assume applies to the final solution of all vertical screens, is nothing to shake a stick at. I will read on though.	Per discussion during the workshops and per field visit of the manufacturer representative, there are promising signs that ROMAG rehabilitation can improve the system operation to some extent. Extent of improvements can be determined in practice. Also, per clarifications provided during the workshop about the phasing of Alt A & G, the cost difference between these alternatives is expected to be higher.	No
69	5	4,4	Nastally	Inserted word "that"	"that" inserted where indicated.	Yes

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
70	5	8,2	Nastally	Have you verified via the videos that this is what occurs? My understanding is that before water starts flowing through the screens that the screens turn on pre-emptively as to not be starting from behind.	The videos of the last five events at the time of drafting the TM showed many anomalies. Some screens were coming on before the flow started (~Elv. 108'), while others stayed off. Those screens that came on a few minutes earlier than starting flow soon turned off after a few minutes of flow through the screen. The turning on and off at different events were random, and no pattern was observed. Based on the discussion with the operator on 01/26/23, the anomalies could be attributed to the manual operation or signal loss/equipment fault. Some clarifications were added to the TM about the exact expected turning on and off set point of screens based on SOP (screen on at Elv. 110' (13' depth) and off at Elv. 109.8' (12.8' depth). Based on O&M, ROMAG screen should not run while the bottom of the screen is out of water to prevent damage to the equipment while running dry.	Yes
71	5	13, #2	Nastally	Deleted '	Apostrophe deleted where indicated.	Yes
72	5	13,list	Nastally	Periods added to end of sentence in numbered list	Periods added as indicated.	Yes
73	5	13, #5	Nastally	Changed "operation' to "operating"	Word changed as indicated.	Yes
74	5	13,5	Nastally	Provide date.	Added	Yes
75	5	15,1	Nastally	Replaced "gpm" with "cfs"	"gpm" replaced with "cfs"	Yes
76	5	15,1	Nastally	@David McCord Isn't the TTS gate supposed to be open to 20	From design team: Yes, but during this specific event the gate was open at 12.5% and was sending about 15 to 25% flow to TTS	No
77	5	15, 1	Nastally	CFS?	Yes	Yes
78	5	15,1	Nastally	Modified wording	Wording in sentence modified as indicated.	Yes
79	5	17,3	Nastally	What is this data, what tags did you use, and how exactly are you getting this interpretation?	More details about data points, findings and a sample graph for one event were added with a description	Yes
80	5	17,3	Nastally	@David McCord Please confirm this is your understanding.	The 12 percent open of the TT Gate was discussed in WS No. 2 including gate position observe during ride-along site visit. Dave and Chris may discuss further.	No

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
81	5	17,3	Nastally	Were observations made / discussed with the operator about manual versus automatic operations?	Yes, a separate Team meeting with the operation team and CDM Smith team was held on 01/26/23. Based on the operator's inputs and notes, the anomalies could be attributed to manual operation or signal loss/equipment fault.	No
82	5	19,2	Nastally	Insert "side"	"side" inserted where indicated.	Yes
83	5	19,3	Nastally	Above, however, you keep saying 12%.	12% is based on existing SOP. 12.5% was observed during the wet weather event operation at that specific event, resulting in 15% to 25% side flow. The 20% is mentioned by Dave as their current goal. Although these #s have some variations, the goal is to keep the minimum side flow to 10% of inflow which seems can be achieved by both 12% and 20% opening. The further hydraulic simulation aims to define the gate opening for the new design peak flow. Having an automatic control to adjust the position of the gate to maintain min 10% side flow to TSS is an optimal solution.	No
84	5	20,5	Nastally	Deleted "s"	"s" deleted as indicated.	Yes
85	5	22,1	Nastally	Wouldn't the screenings then wrap around the gate?	Yes, there is a possibility for that. However, per discussion with the manufacturer that is provided in the following paragraph, this modification is not recommended due to a lack of real data from past experiences and a lack of a need to change the gates that don't show signs of corrosion or malfunction.	Yes
86	5	22,2	Nastally	But why are we separating this from the all romag option?	See the response above about the lack of practical evidence.	No
87	5	22,4	Nastally	It's influent per channel, right?	Yes, however, in practice, due to the turbulent condition of the flow through the screening inlet channel, it is hard to measure the flow in each channel, and adjusting the side flow for each channel will be challenging and add more complexity to the operation. So, the min 10% side flow can be controlled in a more practical way based on flow measured at TTS and changing the TTS gate position.	No

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
88	5	22,4	Nastally	What percent open would this correspond to? Are we hitting the mark or not? I was told we were...and what happens when the side flow is greater than 10%?	In some of the past events, it was observed that the TTS gate was closed, and the side flow was almost zero. However, in the event on 2/27/23, the gate was open 12.5%, and side flow exceeded min 10%. The further hydraulic simulation aims to define the gate opening for the new design peak flow. The gate position to transfer min 10% to TSS will be affected by the downstream level.	No
89	5	23,1	Nastally	Laser flows?	The turbulent flow condition and a considerable amount of swirling observed during an event in the screening inlet channel make it hard to measure the flow in each channel. So, adjusting the side flow for each channel will be challenging and add more complexity to the operation and need more instruments. So, the min 10% side flow can be controlled in a more practical way based on flow measured at TTS and changing the TTS gate position.	No
90	5	23,2	Nastally	Is there actually an option for this?	After receiving more input from ROMAG manufacturer, the answer for that screen is no. However, multi-rake screens have these option. The text changed for clarification.	Yes
91	5	24,2	Nastally	Replaced "at" with "to be"	"at" replaced with "to be" where indicated.	Yes
92	5	24,4	Nastally	Sentence does not read properly	Corrected.	Yes
93	5	30,1	Nastally	What if instead of this, we just replaced both COPAs with these? Could we do this? OR because of the larger screen needed, would this not really be an option?	It is feasible but needs multiple screens on the sides of channels, and controlling the downstream level of these screens to limit the max slot velocity will be very challenging due to the existing structure configuration. So, the final system will have more complexity that would not match guiding principles, and perpendicular installation of screens is not very common, and there are limited past installations in this arrangement. So only one manufacturer felt comfortable about it.	No
94	5	38, bullet 10	Nastally	As written this is confusing...revise it.	Edited	Yes
95	5	39, bullet 3	Nastally	As written this doesn't make sense.	Edited	Yes

Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
					redundant pair of sensors on the upstream and a redundant pair on the downstream of each wet well.	
108	7	1,2	Nastally	For the "spares" should you coordinate with Burns & McDonald to ensure they have sufficient spares installed as a part of their controls improvements?	CDM Smith has conducted one coordination call with Burns & McDonnell to coordinate between the two projects at Leib. Spare points / slots availability is being coordinated.	No
109	7	7,2	Nastally	Do we talk about the future pipe diversion from Meldrum?	This would not effect instruments at the facility. New connection is proposed upstream of the flow/level sensor in the Mt. Elliot sewer.	N/A
110	7	7,4	Nastally	Can you please confirm who is the design team here?	The design team refers to CDM Smith and their sub-consultant on this project. The instrumentation work for this project is being completed by a combination of CDM Smith and PCI personnel.	Yes
111	7	7,5	Nastally	I don't understand what this last sentence means...in relation to the sentences before it.	Sentence was cut off. Supposed to read "LIT-3 will not be considered for replacement or re-calibration as part of this project."	Yes
112	7	7,5	Nastally	Delete word "in"	Deleted	Yes
113	7	7,last	Nastally	Where do we talk about relocating the MCC for the chemical feed pumps to outside of the chemical room?	Relocation of MCC / local control panels to outside the chemical room is discussed under a separate TM. Language has been added to TM-7 for communicating via a digital / Ethernet link to the new soft starters.	N/A
114	7	9,1	Nastally	The title of this section 2.2 was LEIB and here we talk about Oakwood. Please fix. What is missing? Where do we talk about process cameras at Leib?	Copy and paste error on the text. Process cameras will be installed at both Oakwood and Leib under this project. Coordination will be completed with Metco project to identify any overlap and follow the standards developed under that project.	Yes
115	7	9,2	Nastally	I'd really like a section dedicated to Leib, and one to Oakwood...fully. It makes the read easier.	The design team evaluated providing dedicated sections for OKW and Leib for the level sensor evaluation in Section 3 and concluded Leib coverage so limited that clearer to maintain within same subsection which also is better aligned with the TM template guidance as the design team works toward a degree of consistency from TM to TM.	N/A
116	7	9,2	Nastally	Add s to "provide"	Corrected spelling	Yes

GLWA Contract - 2101475
CSO Facilities Improvements Project
Study Phase Technical Memorandum Comment Resolution Form

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
117	7	11.3	Nastally	Replace “that” with than	Word replaced	Yes
118	7	12,1	Nastally	You must reach out to Chris VanPoppelen and ensure he wants this same standard incorporated.	Reference to CS-108 standard has been eliminated from document as it relates to the water side of GLWA facilities.	Yes
119	7	12,5	Nastally	I never did see another option, unless it was "rockwell" hardware in paragraph 2.	Language has been added to identify PLCs / Rockwell hardware as an option for integrating I/O signals into the existing Ovation DCS.	Yes
120	7	12,5	Nastally	Replace word, “are” with at	Word replaced	Yes
121	7	12,5	Nastally	Identify the CIP # 260617, and the project number here for this.	Noted, project number has been added to TM to reference Burns & McDonnell project at Leib.	Yes
122	7	12,5	Nastally	Is there a better place to install it that will result in less conduit installation? Because I would think we can utilize fiber optic communication from the remote I/O back to the main I/O which will save on installation.	Agreed, installation of a new remote I/O rack would minimize wiring runs to some locations and equipment. Fiber optic would most likely be implemented from the remote I/O rack to the existing controller cabinet.	N/A
123	7	13,1	Nastally	Location will be based on meetings with GLWA during design.	Agreed, location of process cameras will be based on GLWA input during the design.	Yes
124	7	13,2	Nastally	Delete Not used. Section	Removed section and renumbered subsequent sections	Yes
125	7	13,3	Nastally	We don't want 50 level sensors though. Like if I have a level in the west wet well (during wet weather), would it basically be the same as east wet well? For sanitary, I get maybe redundancy is needed, but for storm, I'm thinking east/west can back each other up. Tell me why I'm wrong :)	Agreed, a reduction in the number of level sensors was discussed. Cleanup of the system of obsolete sensors and their signals will be included. Redundant sensors will be included for the upstream and downstream sides of each wet well.	Yes
126	7	13,4	Nastally	Identify	Assume this comment is requesting the language to be modified to identify the CIP number for the Burns & McDonnell project at Leib. Language has been updated to include the GLWA contract #.	Yes
127	7	14, bullet 2	Nastally	plan view should show camera coverage / cone of view.	Agreed, language has been modified to indicate the plan views will show camera coverage / intended cone of view for the process cameras.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
				through is not load bearing, then it would be the same as this alternative # 2, except we don't install a beam that we have to maintain against corrosion. What am I missing here?	providing a new means of removing the fan from the room. The current method for removing the fan is described in comment #30 response.	
140	8	12,1	Nastally	Spelling	Spelling corrected	Yes
141	8	13, 1	Nastally	It seems like it would require maintenance for the frame against corrosion, the issue of getting the fan out / moving it still exists. Unless I'm mistaken here.	Yes. The space is tight, while the existing skid frame is galvanized steel and showing little signs of corrosion. The concept allows the needed additional maintenance access to the key maintenance points. See response to Comment 30 concerning removal of the fan.	Yes
142	8	16, figure	Nastally	The fan would have to come completely out of the room to do this, right? Would the fan lose efficiency and not move the correct amount of air? What is the risk of this steel platform increasing vibration in the fan unit? What are the pitfalls of this option?	a. The operation of the fan would need to be shutdown temporarily, while the fan is temporarily lifted to allow for construction of a new support frame. b. There would be some loss in efficiency with the jog, but not significant. This would be analyzed during the detailed design if the alternate is selected. c. The existing SF-1 has vibration isolators, which can be reused or replaced. The new frame would be designed to limit vibrations while using vibration isolators. Disadvantages are identified under Section 5.0 Alternatives Analysis and Evaluation, 5.1.3. The disadvantages are limited space to perform the work, access points are raised so that a step ladder may be needed, and the availability of space to allow for the NEC required clearances for electrical enclosures.	No
143	8	17, 3	Nastally	Highlighted text	The text preceded by “no”, “further work related to these HVAC Controls is required under the scope of the Project.” Is highlighted. Unclear.	No
144	8	18, 1	Nastally	Highlighted text, extra period	Extra period removed.	Yes

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
145	8	18, 2	Nastally	the issue with this request is that this pulls in freezing cold air in the winter and if it's forgotten on, it will freeze all of our pipes. That is the reason for the occupancy sensor. We can adjust the timing of the sensor, or see if it can be started in SCADA with an automatic timer so that unless occupancy is sensed, it will automatically turn off after a period.	Per the direction given by C. Nastally 4/20/2023 email, this is not an item that is part the Project scope.	No
146	8	20, table	Nastally	What were the items considered in 1 through 5?	Is the maintenance access given to the maintenance points on the SF-1. Both Alternate 1 and 2 provide similar access to the Fan belt and motor, etc.	No
147	8	20, table column 2	Sworth	What information was used to score the costs, are there construction estimates?	The Design Team's understanding of the extent of work needed to complete each alternative described in the memo. For Alt 1 the much larger area of wall that will need to be built including the deeper foundation and more relocation that includes fire riser, domestic water, and more resulted in the lowest score, while the other 2 alternates had similar costs. Alt 2 includes some relocations, and limited masonry and concrete work, while Alt 3, had the steel support frame, and very difficult work area to complete the task. OPCC estimates for the design of Alternate 2, the selected alternative, will be provided during the 30% submission for the Basis of Design.	No
148	8	20, table column 1	Sworth	Should this all have the reality modeling to assess the access?	The Design Team has provided alternate plans and sections showing the access provided. The final product will be modeled.	No
149	8	21, table	Nastally	Select this one.	Replacing the wall mounted thermostat with a similar model that also displays the temperature will be the direction. This direction was discussed and confirmed with Dave McCord, provided the temperature can still be monitored and controlled through the PLC and Ovation.	Yes
150	8	21	Nastally	Delete Not used. Section	Removed section and renumbered subsequent sections	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
151	8	21,4	Nastally	This report was finalized in 2021, not 2013.	This has been corrected	Yes
152	8	21,5	Nastally	Spelling	Spelling corrected	Yes
153	8	22,1	Nastally	Ok, but see my comments on this one above.	Yes, your comment about adding storage racks will be incorporated into design.	No
154	8	23, last	Nastally	Where do you address the requested switch at down here?	Per the direction provided in the C. Nastally email dated 4/20/23, controls for the supply fan SF-1 are not in the scope of this project, nor are they anticipated to be added to the scope.	No
155	8	Meeting 4/18/23	D. McCord	Water lines and chemical feed lines have been freezing and breaking during cold events in the Screening and Disinfection Area (basement). The lines will freeze, and then are found in the spring when they thaw out.	Per the direction provided in the C. Nastally email dated 4/20/23, controls for the supply fan SF-1 are not in the scope of this project, nor are they anticipated to be added to the scope.	No
156	9	1 ,bullet 2	sworth	Removal of the structure in the garage comes at a cost, it could be left in place, correct?	Yes, there is a cost associated with removal of the structure. In the memo, an alternate has been proposed to leave it the odor control ductwork in place, while providing the needed gastight physical separation. GLWA decided to remove the structure to provide this area as usable space in the room.	No
157	9	2, table	Nastally	The basement is unclassified? I'm not sure this is correct. I see it's Main Level - so what is this area?	This area does not exist and has been removed from the table	Yes
158	9	9,1	Nastally	On the east side it would restrict movement around the basin, right?	Yes. However, an option could be to add a second door to the vestibule to make it a pass thru. However, during the workshop discussion the second door was not considered a secure option, and Alternate 2 has been selected to proceed with.	No
159	9	10, figure	Nastally	Can we show the concepts and how they'd look on the site plans?	A site plan has been added to Alternate 1 section to clarify the restrictions of adding the vestibules.	Yes
160	9	10, figure	Nastally	The door should be on the parking lot side...	We understand that the door on the parking lot side was discussed during our previous meeting. However, we	No

Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
					decided on this configuration that provides access to the sidewalks and the ADA ramp. If we were to place the door on the parking lot side, there cannot be a step, and an additional sidewalk with ADA ramp would have to be constructed eliminating some of the parking lots. The Design Team believes this was the more cost-effective alternative to explore.	
161	9	11, figure 4-2	Nastally	I assume this would have foundation requirements too (not shown).	Yes. Foundations are noted on Page 9, 4.1.1 under "Alternative 1 requires the following alterations:"	No
162	9	12,2	Nastally	Extra word?	Word deleted	Yes
163	9	15, figure	Nastally	We keep showing just the west side on here, but don't discuss the east side. Would alternative 1 and 2 work for the east side? I'm thinking no. I'm thinking we could wind up choosing both alternatives, one for each side.	Both alternatives will work for either the East and West Vestibules as noted in the memo. However, the vestibule extension on the east side may require a City of Detroit Variance for encroachment on the setback. This disadvantage has been added to the memo	Yes
164	9	15, figure	Nastally	I want to discuss these alternatives with O&M. I'm thinking this one is the least expensive, but would want to add an awning outside, and potentially extend side walls to get the weather further away from the staff (if it's raining and winds blowing from the west, it's a problem in this space. I think Alternative 1 is the best option, it's just the most expensive one too.	We have discussed both Alternates for solving the classification issues at the vestibules during the Workshop and with Dave McCord. After discussing with Dave, we agreed that Alternate 2 was the best choice, as it provided the open area in the wall needed, and increased the weather protection for the staff at the east and west entrances with an added canopy, supported off of the wall. It was determined that a larger canopy with columns or a partially solid vestibule extension with roof is not needed for additional weather protection. The additional screening to be added to the fence gate panel only needs to be sized to keep out pests like birds, bats, squirrels.	Yes
165	9	20,table, col 3	sworth	Are there estimates?	There are no estimates for these architectural alternates. The decision to proceed with Alternative 2 was determined during TM Workshop 1 and after discussions with the CSO Manager after the workshop, without cost estimates.	No

CSO Facilities Improvements Project
Study Phase Technical Memorandum Comment Resolution Form
TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
166	9	20, table, col 1	Nastally	Also what are the actual criteria that result in a 1, 2, 3, 4, or 5?	For Weather Protection we felt that both alternates provided similar protection from the weather, as they both have exterior gated doors to allow for the needed open area with exterior overhang or canopy. For security, both alternates offered similar security benefits. The scope of the work for Alt 2 far exceeds the scope of work for Alt 1, resulting in lower costs, the range from 1 to 4 is noted to account possible unknowns in the conceptual design.	No
167	9	20, 1	Nastally	Highlighted text. This doesn't make any sense because it would then be a 1 or a 5 only...	The table has been corrected to show the Alt 2 cost score as 5, resulting in Alt 2 with a total score of 12.	Yes
168	9	21,table, col 2	sworth	Cost estimates?	See response for Comment 61 above.	No
169	9	21, table	Nastally	We want this alternative	Understood.	No
170	9	21, table	sworth	Is this truly much different than current? Does that merit a 1?	In the Design Teams opinion, it merits a 1. We are told of the maintenance associated with having to dewater and sometimes send a diver into the duct for inspections, and the duct sticks up in the middle of the Garage, where parking and storage space is limited.	No
171	11	2,5	Nastally	Please confirm GLWA CAD standards were utilized for this.	Yes.	Yes
172	11	2,5	Nastally	Highlighted text. This is included in this TM? Please identify.	Noted, reference to appendix provided.	Yes
173	11	2,5	Nastally	what report?	This paragraph is referencing to the Geotechnical Report.	No
174	11	2, last	Nastally	Coordinate this fact with TM-24 and improvements along Mt. Elliot that were required, but are not any longer.	Noted.	Yes
175	11	4,1	Sworth	PCS-79 Sewer not shown on these drawings, 10' Sewer along west border with about 20' of cover	10' diameter sewer is shown on the drawings	Yes
176	11	5, figure	Nastally	When we pave this, I think we're going to need to place some bollards over here to prevent plows	Noted, bollards provided to protect the existing structures near the proposed pavement.	Yes

187	11	Appendix 43, figure	Nastally	Why is the google image here on to site plan? Fix.	Was kept as a separate page of the soil boring layout.	Yes
188	11	Appendix 170, item 3	Nastally	FIX highlighted text	Updated with the surveying information	Yes
189	11	Appendix 173,1	Nastally	Fix all XXX.XX elevations pages 173 - 183	Updated with the surveying information	Yes
190	15	3,5	Nastally	Insert "the"	"the" inserted where indicated.	Yes
191	15	3, bullet 6	Nastally	There was also a memo by ASI on the recirculation of sanitary flow during storm events. This may not be needed, but can you confirm you are aware of this?	Noted. Not aware of this ASI memo. Key observation from our ride-along visits is that the pumps are not being buried in grit when off-line during wet weather events.	No
192	15	3,2	Nastally	I think right here you need to define what "questions it will actually answer". And what questions it will not answer, and where to find the answers to those questions.	Revised accordingly.	Yes
193	15	7, last	Nastally	Add "ing" to follow	Word modified.	Yes
194	15	8,3	Nastally	Modify sentence as noted.	Changes in sentence made as indicated.	Yes
195	15	10,2	Nastally	You should speculate here on why. I believe it's because of the dip in the curve and that we've always had high vibration and therefore the pumps likely kept tripping out on vibration.	Speculation added.	Yes
196	15	16, last	Nastally	So our plan is to fix this right?	The sanitary pump alarm for high moisture not triggering again in Ovation required further definition. Will identify that this requires a control logic change. This was added to the Next Steps section.	Yes
197	15	17,2	Nastally	Revise sentence, it does not read right.	Revised	Yes
198	15	17,2	Nastally	Have you communicated this to the PACS team, or operations? We should address this right away. Could this be why we're experiencing pump failures? I know you said cracked impellar, but just curious if this is a cause...i.e. burning them up.	Communicated to Dave with suggestion to loop in the PACS team to Scott. This could be contributor if not caught during manual operation as pump would be below min water level below 40.2'. This would lead to potential seal damage resulting in leakage and then stator damage observed. Pumps equipped with closed cooling loop thus not likely	No

					burning up. Frequency and duration of occurrence would contribute. Wet well level data review identified less than 0.1% east; 0.5% west of time below 40.2' (based on calibration of in-service level instrument).	
199	15	20,2	Nastally	Correct spelling of dominant.	Spelling corrected.	Yes
200	15	21,1	Nastally	Insert "are"	"are" inserted where indicated.	Yes
201	15	22, bullet 2	Nastally	Any ideas or correlation?	Evaluated further to assess if a correlation with other operating pumps in vicinity of units with elevated vibration amplitudes focused on ST1, ST2, & ST3 based on summary in Table 3-3. These are the units where noted vibration >0.5 in/sec at times when pump not running. The dates with very high vibration spikes (>0.5 ips) for ST1 and ST3 did not have another pump in service. ST2 most of high vibrations for this pump were while the pump was running. When high vibration levels and pump is not running, there were no other pumps running either. There was one common date, 10/20/22, between all 3 pumps, but at various times between 5:45-7:00AM. This time frame could coincide with activities at the pump station which were independent of the storm pumps but resulted in vibration within the structure being transmitted to the pumping units.	Yes
202	15	23, 3	Nastally	What is the status of CDM investigating this, the failure of pumps, removal of the bar screen, and perhaps adding mechanical screens to this?	Obtained insights from Kennedy Industries through four SN pump condition reports. A summary of findings was reviewed with GLWA in a meeting held 5/24/23. The lack of understanding of where pumps located relative to the removed bar screen section impacts ability to conclude if cause of failures of sanitary pumps were a result of screen removal. CDM Smith identified that more likely due to operation outside the AOR leading to reduced seal life coupled with moisture alarm clearing practice observed which may result in the associated stator and terminal board damage which is the most common failure mode reported.	No

203	15	24,1	Nastally	This is interesting considering our plan to perhaps do 2 at a time. We probably will need more analytical data on this. Like if we only turned on 5, and let them run a bit longer, would it still have been ok in terms of flooding? Did you pull data longer than last 3 years on on/off? Since this relates to our rehab strategy, I think we're going to need to be able to make EGLE comfortable.	Noted, although inherent event to event variability exists. Our ability to predict if will be ok as projected in comment is limited. However, we have obtained rainfall data and more pump runtime data to assess number of storm pumps in operation over more than the last three years. This is summarized in Table 3-5 which has been revised to reflect the additional analysis findings including number of pumps in operation at one time, duration at maximum number of pumps and wet weather event maximum measured wet well level. We did so with consideration of future coordination with EGLE and other involved stakeholders. We propose to rely on the recently obtained expanded dataset as basis for assessment of risk that event will require more than 5 pumps in operation such that still would be N+1 with the sixth on-line pump.	Yes
204	15	24,2	Nastally	Do we know what the associated total rainfall near Oakwood was for these events where 5 and 6 pumps ran?	Event rainfall total and peak hour was added to Table 3-5.	Yes
205	15	25,1	Nastally	This requires the operator to record it running, which can easily be missed in the haste of a larger event.	We are working with the Operator's who recorded the events for conditions which are highly unusual. However, it is possible to miss a pump if a lot going on and limited staff on-site. There are also opportunities to misinterpret in the historized data when attempt to turn on a pump and it fails to start but the data indicates the pump turned on or timing of one pump turning off and the next one turning on. In these cases the log book may be more reliable. Each major multi-pump event identification has potential for on-line pumps to be missed. Additional analysis was conducted to better assess the number of operating pumps based on runtime data obtained from the GDRSS recorded data and compared to major rain events as now summarized in the TM.	Yes
206	15	27,	Nastally	This doesn't read right. Fix.	Revised for clarity.	Yes

		bullet 5				
207	15	28, bullet 2	Nastally	Our future design must consider this...we don't want bleach pumps to take storm pumps out of service.	The future design does consider this with the metering pumps discharging to a common discharge header from which control valves to individual storm pumps will be provided.	No
208	15	28, bullet 4	Nastally	Insert "the"	"the" inserted	Yes
209	15	28, bullet 14	Nastally	Change "pump" to "pumps"	Word modified.	Yes
210	15	28, bullet 6	Nastally	Was this discussed with Flygt?	This was discussed with Xylem, Flygt AC Custom pump, the OEM. ST-5 was modified by Kennedy with the swap of line shaft and bowl bearings from Thordon SKL to cutlass rubber which is more flexible. Xylem indicated that when running this far to the left, recirculation and increased vibration would be expected. It is possible that with the increased vibration the impeller is intermittently touching the cone causing the bang. Also, as a follow-up to this insight CDM Smith asked about insufficient NPSH margin. Xylem did not respond, possibly due to not collecting NPSHR data this far left of AOR left limit.	No
211	15	29, bullet 7	Nastally	Awesome! Is it this leading to more frequent pump failures? What's up with the mechanical seal?	Yes, it likely is. Mechanical seal may be failing sooner than anticipated due to sustained operation outside the AOR as discussed at 5/24/23 meeting.	No
212	15	29, last	Nastally	It would seem like the failure of the gates at the wet well would cause this. You can draw it down, but it doesn't really make a difference, right?	Assuming referring to the pinch valves in the upstream junction chamber, expect that the sanitary pump could operate at a rate greater than influent flow rate under dry weather conditions resulting in the desired draw down of wet well for short duration.	No
213	15	29, last	Nastally	Insert "is", make do, does.	Wording modified.	Yes
214	15	31,3	Nastally	This analysis is interesting.	Noted.	No
215	15	34, last	Nastally	Fix sentence.	Revised.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
216	15	35, Table 3-6 Notes	Nastally	Does this reduce overall pumping capacity below 1675 cfs? Based on your sheet it doesn't look like it with 7 pumps on, but then just curious as to what this means.	No this does not reduce overall firm pumping capacity as able to operate at 100% speed with VFD speed controlled pumps. The highlighted statement means less turndown of the small pumps to allow control system to operate all pumps at the same speed.	No
217	15	41, Section 3.6 Bullets	Nastally	OK	Noted that ok with our recommendations which differ from CS-299 report/B&C TM for pump speed range and minimum wet well level.	No
218	15	42, Table 3-9	Nastally	I see no issues with these recommendations...as long as they're programmed into SCADA.	Noted. Confirmed the operational strategy will advance to the associated specification section and ultimately be programmed into Ovation.	No
219	15	42,3	Nastally	One question about our permit...can you review the NPDES permit and ensure this proposal would not put us in violation of our permit...like certain limits established, etc.?	The NPDES permit was reviewed relative to sanitary flow rate limits or constraints for OKW to determine if proposed operational strategy would result in a violation. We found the following: permit does not specifically provide operational constraints on sanitary pumps, but references regional operating plan which (in detailed op. plan version only, not directly linked to permit) provides maximum dewatering flow rate of 23 cfs. No other operational constraints.	No
220	15	42, last	Nastally	Should we consider now? Once the above is programmed into SCADA, I would think it's going to stick for a while. So we either change pumps and change that, or we stick with what we got. I'm ok with what we got as long as it doesn't violate our permit	Given the budgetary sensitivity and the investment in the sanitary pumps (approx. \$150,000 each) recommend retain existing pumps. We had heard that additional pumps may be purchased soon from KI a couple months ago. See response immediately above for permit considerations.	No
221	15	44,4	Nastally	I would like this in a table eventually. All of these.	Noted. The storm pump cycling through pumps as flow rates increase can be summarized in table as part of the control description specification. Included as a next step.	Yes
222	15	45,1	Nastally	Why not first started? Wouldn't this help to balance run hours? I believe it has to do w/ VFD...but could it be first constant speed started is first off, first vfd is first off, when we get to those thresholds?	Revised to reflect first started of each pump size/ speed control type (VFD speed controlled or constant) will be first off as step pumps off to allow runtime distribution.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
223	15	45, last	Nastally	I only want an alarm, and the alarm can be scaled. Like if we're 0-33% over, it's an alarm that lets me know, if its 33-100% over, it tells me is causing damage and recommends me to shut it down, or something like this. I want to retain control, and not have it automatically shut it down until there is a catastrophic level (I don't know what that level is) where pump damage or endangerment of PS operations lifes is expected. Make sense? Maybe it can recommend starting another pump, and when that happens, they can shut down and lock out the problem child...thoughts? @David McCord Please concur. Like if the alarm goes unacknowledged for more than 60 minutes, and it's above 33% of allowable, it will then automatically shut off...or something like that. Dave - thoughts?	Recommend that the alarm and recommendation for shutdown be defined in the BOD phase with GLWA input from Dave McCord and other stakeholders, proceeding as recommended by Chris. This monitoring plan and associated operational strategy changes would also consider the capabilities and constraints of the Multilin protection relay which receives the vibration velocity inputs and the vibration switches. This path forward was clarified in Next Steps section.	Yes
224	15	48,3	Nastally	Lead pump doesn't turn on until 75 or 76 (right), so we need sanitary pumps to either run to this point, or shut off at 62...let's discuss.	Lead storm pumps to turn on at 73', indicating sanitary pumps required to operate until point that storm pumps start? This has not been operational practice. This was discussed at the 5/12 conducted TM WS No. 3 and concluded that operational practice would be maintained as currently performed – sanitary pumps turned off at approximately 62.	No
225	15	48,5	Nastally	As long as this isn't a permit violation, OK.	This proposed maximum flow rate constraint is aligned with the permit requirements.	Yes
226	17	2,5	Nastally	Can you confirm in all samples taken that there was NO TRC in them?	Yes, all samples were taken with no TRC in them. Oakwood samples were taken from the influent wet wells, and Leib samples were taken from the influent channel after turning off the pre-mixers.	Yes
227	17	6,2	sworth	Wasn't the additional sampling completed?	The additional sampling event was completed after submitting the TM 17	No
228	17	6,2	Nastally	Highlighted text, please define this.	Data related to the sampling event or to a future wet weather events like dosage, storage volumes, Flowrates, TRC, Fecal coliform, TSS etc. that can help us to refine the model.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
229	17	Appendix 22,last	Nastally	After Thursday?	Corrected: If wet weather happens Monday through Wednesday, Samples will be shipped to the CDM Smith RTL and analyzed immediately. If wet weather happens after Wednesday, then samples will be collected and shipped to the CDM Smith RTL, stored at the lab, and will be analyzed depending on the CDM Smith RTL staff schedule.	Yes
230	17	Appendix 23, 1	Nastally	Highlighted text, What does this mean?	The field coordinator participated in the first chlorine dose response analysis at the CDM Smith laboratory in Bellevue WA.	Yes
231	18	1,3	Nastally	Correct spelling of Team	Spelling corrected.	Yes
232	18	2, Table 4-1	Nastally	How come Oakwood was never tested at 12ppm, and how come Leib was not tested at lower values than 5 and Oakwood was?	Initial chlorine demand testing was performed on the samples before starting the dose response testing. The doses for each dose response test were selected based upon that chlorine demand testing. Ultimately, Leib had a higher chlorine demand than Oakwood. A paragraph was added to clarify.	Yes
233	18	3, Table 4-2	Nastally	How was temperature taken by them and not the person grabbing the sample?	This is the temperature for the dose response test, which is performed in the lab. It is not the temperature of the raw CSO flow at the time of sample collection.	No
234	18	8,1	Nastally	Conservative = oversized. I don't like where this is heading already. St. Aubin used conservative values for the system too, and we struggle to dose in anything other than plug flow because the system is waaaaayyyy oversized.	While ICT selection followed a conservative approach, the proposed feed design (TM20) includes turndown capabilities, allowing for delivery of a range of chlorine dose and flow conditions.	No
235	18	8,	Nastally	These systems must be sized to handle the largest, but this isn't in reality where we spend most of our time at. We spend most of our time at the other end of this conservative spectrum and operators struggle because engineers get conservative and oversize everything. I want to make sure this is recognized and want to understand what CDM is going to do to overcome this.	While ICT selection followed a conservative approach, the proposed feed design (TM20) includes turndown capabilities, allowing for delivery of a range of chlorine dose and flow conditions.	No

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
236	18	8,1	Nastally	Did CDM obtain water quality data from the WRRF?	Yes, but there are no historic undisinfected bacteria data available from the WRRF.	No
237	18	8,2	Nastally	This may or may not be true. We could have had a snow melt event the week before that could have flushed out the pipes. What was total rainfall for each event? Did CDM obtain this data from GLWA CSO Operations team?	An analysis of rainfall data was added to the TM to address differences in TSS and chlorine demand across the sampling events.	Yes
238	18	10,1	Nastally	Were we adding Chlorine (CL2) or Sodium Hypochlorite (NaOCl)? I know I'm not a chemist...and I recognize they do the same thing...but how do the results port from one to the other?	Sodium hypochlorite is the term used for the delivery, storage and feed, while chlorine is used for the dose and residual.	No
239	18	12,	Nastally	It's not a "theory". What does this sentence mean?	The word "theory" was deleted for clarity	Yes
240	18	18,1	Nastally	Why 200? This seems to add a factor of safety of 2 = 2x larger than it needs to be for the worst case (first flush in the summer). Help me understand.	From a log-reduction standpoint, decreasing coliform counts from 400 to 200 represents a 12% decrease. It is not recommended that the system be designed to the 400 CFU/100mL value, which represents a maximum permit limit during the recreation season. Using a value of 200 CFU/100mL accounts for variability in influent water quality and system performance. The text was updated to provide clarity.	Yes
241	18	19, last	Nastally	Ok, but will be considered in the design of the system?	Yes, the 2/27 Oakwood Inactivation Goals were considered in designing the minimum capacity of the feed system.	Yes
242	18	30,1 (overall comment on TM)	Nastally	In my opinion, there was a lot of technical jargon in this memo, all fine, but it should also provide explanation in terms we commonly reference. For example, the maximum dose the system will be sized to, and the minimum dose the system will be sized to in mg/L of NaOCl, and what this does in terms of pump number and pump size as compared with existing. What is the existing system sized at in comparison to what the proposed system is sized at, in total (from the highest NaOCL concentration to the lowest).	The sizing of the system, and comparisons between existing and proposed design criteria, are discussed in TM20.	No
243	19	3,3	Nastally	Where does the data come from, and how & what database does it get fed into to actually support this?	The data from the upstream water characteristics originate from the sensor to be evaluated and described in section	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
				Have you had conversations with GLWA PACS team regarding this?	4.1.4.3 and Table 4-2—precipitation data from rain gauge sensor and NOAA source. Data will be gathered via Ovation integration to be defined in I&C design. This will be discussed with GLWA PACS team (Bassem Almatar and if needed Chris Vanpoppelen. The discussion will be focused on the security related consideration for the edge computer and access through Ovation.	
244	19	3,4	Nastally	How will we incorporate this into the delivery of the project? Will disinfection be installed, and able to gain sufficient data while the storm pumps are still being rehabbed into order to tweak? What exactly would be installed on the SCADA system (to actually make it "machine learn")?	The design delivery, data collection, and model development are defined in detail in ML section 4.1.4.3 Project Work Plan. In summary, the project scope is to evaluate the feasibility of incorporating modification of the ICT approach and the potential for an ML dosing model to optimize system operation across multiple flows and bacterial loading scenarios estimating. The model will be evaluated with test (Unseeing = new) data offline. The evaluation will compare the model prediction with the measured value. If the feasibility study is within the expected performance, an implementation phase will be recommended as part of the final report.	No
245	19	4,1	Nastally	Please also discuss with Andrea Busch. She worked on a trial for us, and I'd just like to understand if she concurs here. I'd also like Dave McCord's buy in too!	TM text has been updated based upon input from Andrea Busch at TM Workshop 3 which are summarized in the meeting notes for that workshop. Team is proceeding based on the insights and path forward defined at the workshop.	Yes
246	19	5, ES-1	Nastally	Do we need the same size?	Pump flow capacity could be lowered. The sample piping will be reused, and pump flow capacity could be lowered to 75 gpm to maintain minimum velocities. Following text added in Section 4.2: "During basis of design phase, the feasibility of reducing flow capacity and option of Flygt N series pump will be evaluated."	Yes
247	19	5, ES-1	Nastally	This seems like a bit...How does this fit into our guiding principals for the project?	Subsection 4.2.1, Table 4-3 provides explanation about proposing six sample locations. Multiple sampling locations will be needed to cover the different flow scenarios,	Yes

					operation of different storm pumps, and different screens in operations. This was discussed at WS No. 3 on 5/12 and highlighted the TM sourced summary why three sample pumps each with two sample draw offs are recommended. GLWA offered input and concurrence during the workshop as summarized in meeting notes. The alternate sampling approach showing 3 submersible pumps is added to the TM, along with the associated figures. This approach is recommended. The exact location of the TRC analyzers will be evaluated in the Basis of Design Phase.	
248	19	5, ES-1	Nastally	Also - why so many sample locations? Doesn't the water essentially mix into a common chamber that utilizes all screens? How would the six sample points be analyzed then if we did, averaged?	Subsection 4.2.1, Table 4-3 provides explanation about proposing six sample locations. Multiple sampling locations will be needed to cover the different flow scenarios, operation of different storm pumps, and different screens in operations. This was discussed at WS No. 3 on 5/12 and highlighted the TM sourced summary why three sample pumps each with two sample draw offs are recommended. GLWA offered input and concurrence during the workshop as summarized in meeting notes. The alternate sampling approach showing 3 submersible pumps is added to the TM, along with the associated figures. This approach is recommended. The exact location of the TRC analyzers will be evaluated in the Basis of Design Phase.	Yes
249	19	7,1	Nastally	Delete extra space between words.	Space deleted.	Yes
250	19	7. last	Nastally	Delete extra space between words.	Space deleted.	Yes
251	19	11,1	Nastally	Add "d" to word.	"d" added where indicated.	Yes
252	19	12,3	Nastally	Insert "The" at beginning of sentence, modify effluent to lower case.	"The inserted and word modified	Yes
253	19	15,3	Nastally	Change 'come' to 'came'	Word modified.	Yes
254	19	15,4	Nastally	I am ok with switching to a TRC analyzer based system, but we must have the ability to do it manually also, as a part of the design. SIMPLE.	Manual Mode will be part of design.	No

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
255	19	15,5	Nastally	Please expand. This causes what? This is a concern why?	Excessive chorine off gassing may result in corrosion of metal items in the vicinity. Following text added 'Excessive chorine off gassing may result in corrosion of metal items and be a health and safety concern in the vicinity.'	Yes
256	19	16,1	Nastally	Deleted "from the"	Words deleted.	Yes
257	19	20,2	Nastally	Fix. Doesn't make sense.	The paragraph was changed to "The ML problem to be resolved requires the development of a supervised regression model to predict chlorine demand based on CSO flow, environmental factors, and upstream properties. "	Yes
258	19	20,2	Nastally	Change w in water to lower case.	W changed to lower case.	Yes
259	19	24,1	Nastally	Add "s" to consideration. Replace "taken" with "incorporated"	Wording modified as indicated.	Yes
260	19	24,bullet 3	Nastally	Delete extra period.	Extra period deleted.	Yes
261	19	24,2	Nastally	Modify denoised to denoising	Word modified.	Yes
262	19	26,2	Nastally	So far, the one thing I haven't necessarily seen is where this "model" is truth checked. Where do people come in and input data that tells the "model" its full of crap, or it's spot on?!!!!	The ML workflow describes that a Model metric definition and analysis will be defined during design; the data collected will be divided into two sets 70 to 80 % for training and 30 to 20% for testing. The model is trained using the training data and it's performance is check using the testing (Unseeing = new) data. The metrics will be used to justify the feasibility of the model. Text was updated to include a description of how the data is used to train and test the model.	Yes
263	19	27,6	Nastally	Is it one year, or so many rain events?	The duration is one year with assumption that will be events that activate the facility disinfection system. As noted in WS No. 3, at Leib this may extend beyond one year.	No
264	19	29, bullet 3	Nastally	It is also possible that 6 months of data provides more than enough.	As discussed at WS No. 3, CDM Smith anticipates that one year will be required to generate a sufficient data set necessary to train and then test the model. In addition, would like to include every season which requires the one year duration.	No
265	19	29, Section 4.2	Nastally	Insert "a", add "s" to provide.	Modifications made as indicated.	Yes

266	19	30,2	Nastally	Modify adaption to adaptation.	Word modified.	Yes
267	19	31,1	Nastally	Add "s" to "event". Insert "a"	"s" added. "a" added where indicated.	Yes
268	19	49,1	Nastally	We have to talk about how these are going to be incorporated into the actual operations & SCADA operations, and also the training we provide to the operators on each.	Anticipate further discussions as the design process continues. Each task includes updates to the system O&M manual and training of O&M staff.	No
269	19	53	Nastally	Text formatting	Proper formatting verified.	Yes
270	20	2, bullet 2	Nastally	When we replace tanks at both facilities, lets ensure the piping, configuration, layout of them afterwards, and how they'd be changed in the future is fully thought though so we don't create future extra work, or make our everyday lives in O&M more difficult.	Will consider existing and potential future needs, and operations and maintenance requirements when developing facility layout. Will engage GLWA staff for feedback on design. Modified text in next steps section under GLWA Coordination subheading to incorporate this in the design.	Yes
271	20	2, bullet 4	Nastally	@David McCord you will want to be very aware of this in the future. It will be similar to Hubbell Southfield.	Discussed with Dave McCord during May 12, 2023 TM No. 3 workshop. It is understood there is no action required to update the technical memorandum to address this comment.	No
272	20	2, bullet 5	Nastally	Change "once" to "in anticipation of"	Wording modified.	Yes
273	20	2, last	Nastally	Insert "facilities".	'facilities' inserted where indicated.	Yes
274	20	2, bullet 6	Nastally	I wonder if this is determined after dilution. Can you confirm? I'm pretty sure they actually deliver near 13%	Correct, 7.5% is after dilution and not as delivered. Updated description of value in TM.	Yes
275	20	4,1	Nastally	Insert "the" before Hubbell, change Connor to Conner.	"the" inserted where indicated. Conner spelling corrected.	Yes
276	20	17, Figure 2-2	Nastally	Some text is cut off. Fix.	Corrected figure to prevent text from being cut off.	Yes
277	20	28, bullet 2	Nastally	Was there effluent data from the basin? How did it compare to that? Also, basin is a fixed volume before discharge begins, so it can be checked. So was this done and was it close to the "reasonably accurate" pump data?	At Oakwood, chlorine is added only when the storm pumps are added. The analysis includes flow where hypo was added (i.e., Oakwood storm pumps are active), which includes flow that was not discharged over the basin effluent weir. Therefore, storm pump flow data is required to account for the portion of flow that was treated with hypo but not discharged to the outfall. This accounts for the volume in the basins not being fixed.	Yes

TMs Submitted 3/20/2023, 3/24/2023, 4/10/2023 – Review Comments Received from 3/22/2023 thru 4/19/2023

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
					As discussed in the May 12, 2023 TM No. 3 workshop, a comparison between the storm pump flowmeter reported flow and flow predicted from the observed pump speed and pump performance curve was used to evaluate the potential impact of the inaccuracy of the existing flowmeters. Single point of comparison suggests the historic chlorine dose could be ~30% lower than as determined using historic flowmeter data and chlorine tank levels. The recommend ICT based dose would still be below the adjusted historic average dose (150 lbs/MG). GLWA and CDM Smith agreed this was sufficient to assess the potential impact of the flowmeter inaccuracy. Results from flowmeter accuracy sensitivity analysis are included in updated TM.	
278	20	29, bullet 4	Nastally	Decreases in tank levels is more likely due to leaking drain valves.	This statement was in reference to tank level changes that were comparable to storm events (i.e., considerable tank level change in relatively short duration). Added statement to indicate that prolonged decreases in tank level could be attributed to leaking valves and were also not included in the historic dose analysis.	Yes
279	20	29, last	Nastally	Wow!! Is that even right?	For this event, Tank 1 level dropped 6.2 feet corresponding to 7,130 gallons of hypo used. According to EGLE reports the storm event was 9.99 MG. Chlorine concentration was 10.8% so it doesn't appear the operator was using the storm event to dump low concentration chlorine. Events with similar hypo usage had flows 3 to 4 times this event with doses closer to the median value of 23 mg/L. This appears to be a legitimate data point.	No
280	20	29, last	Nastally	Did you calculate when it was overflowing (we do weir calc for overflow - more robust).	Effluent weir calculation was not completed because the storm pump flow data was used to account for flow that was not discharged to the outfall but was treated with hypo. This accounts for the volume in the basins not being fixed. As discussed in the May 12, 2023 TM No. 3 workshop, a comparison between the storm pump flowmeter reported	Yes

					flow and flow predicted from the observed pump speed and pump performance curve was used to evaluate the potential impact of the inaccuracy of the existing flowmeters. Single point of comparison suggests the historic chlorine dose could be ~36% lower than as determined using historic flowmeter data and chlorine tank levels. Added flowmeter accuracy sensitivity analysis results to the updated TM.	
281	20	29, last	Nastally	What are the typical / historical measured TRCs?	Historically TRCs range from 1.1 to 2.8 mg/L at Oakwood and Leib. TRCs tends to be higher at Leib than Oakwood.	No
282	20	35,1	Nastally	Delete "s" from relations.	"s" deleted.	Yes
283	20	35, bullet 4 & 5	Nastally	This will need to be specifically highlighted with operations.	Discussed impact of sodium hypochlorite concentration on storage requirements under various design scenarios during TM 3 workshop held on May 12, 2023. It is understood there is no action required to update the technical memorandum to address this comment.	No
284	20	36, bullet 3	Nastally	Is this provided?	A copy of the Chlorine Contact Chamber Design and Flow Evaluation worksheet can be provided as an appendix item in the final TM.	Yes
285	20	37, Table 3-5	Nastally	Why is a design peak of 1,071 versus future collect system max of 794 yield opposite in terms of contact time?	At 1,071 mgd two CSO basins are in service while at 794 mgd one CSO basin is in service which increases the effective volume considerably for the 1,071 mgd scenario. See third row of table where the number of CSO basins in service is listed for each flow scenario.	No
286	20	37, Table 3-5	Nastally	If all else is equal, wouldn't 1071 be less contact time than 794?	At 1,071 mgd two CSO basins are in service while at 794 mgd one CSO basin is in service which increases the effective volume considerably for the 1,071 mgd scenario. See third row of table where the number of CSO basins in service is listed for each flow scenario.	No
287	20	37, Table 3-5	Nastally	TRC as measured where at?	At the effluent channel downstream of the CSO basins. Added sentence after Table 3-5 to clarify. Clarification also added to Leib discussion Table 3-10.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
288	20	40, Table 3-7	Nastally	If we "ruled" out baffles, why are we saying "proposed baffles"? Or maybe we state later on again...and proposed storage is 30K.	Conclusion that baffles are not recommended is included in the executive summary and after table 3-7. Changed description to "Baffle Alternative" to clarify baffles were a consideration and not necessarily recommended.	Yes
289	20	41, Table 3-8	Nastally	Out of curiosity, would this ICT change if we had better / more accurate flow data? How does this compare if you use the "nominal" values of the pump, and work with Steve Fehniger to approximate flow based on Pump On and VFD speed?	No. Historic flow data does not impact ICT or required dose. ICT is based on chlorine response test results and required dose is a function of ICT and effective contact time at various design flows conditions.	No
290	20	41, Table 3-8	Nastally	Want to make sure we discuss this with McCord make sure he understands. I also think the "future" condition will never happen.	Discussed storage requirements under various design conditions during TM 3 workshop held on May 12, 2023. It is understood there is no action required to update the technical memorandum to address this comment. The working volume is shown for the future collection system condition as required to accommodate it whenever it is constructed.	No
291	20	48, Table 3-9	Nastally	So if I read the above bullet correctly, this is the feed rate at 5%, correct?	Yes, this flowrate corresponds to 5% sodium hypochlorite concentration. Added footnotes to table to clarify.	Yes
292	20	54, Figure 3-17	Nastally	For original - shouldn't it be 56,000? Are the numbers right here? Original, per your table above is 10% 56,000, with asbuilt 10% 22,000. Can you help me understand what I'm missing?	The 56,000 gallons from the original basis of design and 22,000 from as-built condition are under the peak design storm condition (Figure 3-18). Figure 3-17 presents storage volume requirements for two average design storms.	No
293	20	56, bullet 7	Nastally	When we make these tanks taller, make sure we minimize the amount of work required on top (or verify head space is adequate).	As discussed in Section 4.4.1, the design will reduce work required on top of tanks to the extent feasible in design phase or provide adequate head space for work where feasible.	No
294	20	57, Table 3-14	Nastally	@ XXX % NaOCl	Added footnotes to table to clarify % hypo that corresponds to each parameter.	Yes
295	20	59, bullet 6	Nastally	Modify reinforce to reinforced.	Word modified.	Yes
296	20	60, Table 4-1	Nastally	What permissives, or feedback loops would have to fail for this to become a reality?	Flowmeter on the duty control valve station and flowmeter for backup control valve station would need to fail or the electric actuator would need to fail on multiple flow control	No

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
					valves. In addition, for most storm events staff can change the storm pump(s) in operation to provide operable combination of storm pump and control valve station. Therefore, manual operation is only required after numerous failures of back up system.	
297	20	61,1	Nastally	Modify "summarized" to summarizes.	Word modified.	Yes
298	20	66,1	Nastally	Modify "Recommend" to "Recommended" in Section title	Word modified.	Yes
299	20	66, Section 4.3.2	Nastally	Delete "and Leib and"	Words deleted.	Yes
300	20	70, Figure 4-4	Nastally	Given limited head clearance, we'll need to consider tank access at the top, and head knockers.	Agreed. Maintenance activities requiring access to the top of the tank will need to be accessible from the side of the tank. This will need to be coordinated as the design progresses with tank manufacturers. This is discussed in second paragraph below Figure 4-4.	No
301	20	71, bullet 3	Nastally	We would also need temperature controls and temporary measures of having a temp wall in place, I'm thinking.	Added statements to Leib and Oakwood discussions that temporary wall system and temperature controls would be required to avoid freezing temperatures, reduce degradation of hypo at high temperatures, and keep facility secure during replacement.	Yes
302	20	71, bullet 4	Nastally	Add "s" to appurtenance.	"s" added.	Yes
303	20	73,1	Nastally	Do you want to increase the tank height even more (since we apparently have the head space)? Or will that create "containment" issues? Just curious since this would likely give us a little more cushion.	It appears there is enough secondary containment to accommodate tanks that are several feet taller; however, the limiting factor is whether the taller tanks could be stood up within the room after being passed through the knockout wall openings on their side (smallest dimension). This will require field investigations to verify clearance requirements. We will also have to verify manufacturer capabilities for larger tanks. Recommend considering this in preliminary design phase.	No
304	20	73,2	Nastally	It would be nice if we can re-configure the sump and the stairs to allow access around all sides of the tanks. I feel	Opportunities to modify the sump and stairs can be considered in the preliminary design phase. Added item to next steps list.	Yes

				like not being able to traverse them could be a potential safety issue.		
305	20	76,1	Nastally	The new chemical piping / system needs to have a way for GLWA to actually discharge a tank to the sewer when the tank contents (strength) becomes too weak for us to hold onto the tank anymore. Otherwise, we have no way to dump it. We don't want to dump it through the mixers....there should be direct piping. Consideration of dilution when draining should be made too.	Acknowledged. Will consider provisions for dumping and dilution during preliminary design phase. Added item to next steps list.	Yes
306	20	81, Table 5-3	Nastally	Will recircing bleach at this rate back into the tanks during low-flow / low demand events cause a degradation of the bleach via aeration? Same question applied to Oakwood.	Aeration could degrade hypo. A VFD could be used to reduce the recirculation flow under low feed rate conditions. Locating the recirculation discharge connection near the bottom of the tank could reduce aeration effect but will add head to the pump system. This should be considered further in the preliminary design phase with hydraulic modeling of the system to refine recirculation flow requirements. Added item to next steps list.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
307	21	2, bullet 12	Nastally	Why couldn't we consider on the influent piping and then dose according to total flow and make that dose proportional (to each pump that's on) to the pump on and it's speed and approximate proportion of pumped (nominal based on curves and turn down for VFDs) flow in relation to total flow? Even if we didn't alter for VFDs, the turndown is only to 85% anyways, so it's close enough to 100% in terms of proportion of total flow and nominal pumping capacity, is it not?	Revised TM to include this alternative in the introduction. Upstream flow meter would be calibrated in dry-weather but used in wet-weather. Dry-weather flow conditions are low depth and free flowing into the facility. Wet-weather flow conditions are high depth, high velocity, and subject to backwater conditions from the facility. Oakwood storm water pump operations result in this upstream meter location going into and out of backwater multiple times during each wet-weather event. Related to chlorine dosing: Cannot use influent flow rate for chemical pacing. Will almost always be a difference between influent flow rate and what is being pumped (wet well filling and drawing down). PS influent flow metering would not achieve the primary goal of flow paced and TRC paced dosing. An influent meter would tend to show flow rate changes more gradually and may show changes prematurely or with a delay compared to pump operation. Could lead to over- or under-dosing TRC as flow changes throughout an event. Eight flow meters along the storm pump discharge piping could pick up the rapid changes in flow as pump operation changes.	Yes
308	21	2, bullet 12	Nastally	Wouldn't this also contribute to guiding principal of reduced maintenance?	Captured in new Table 5-2	Yes
309	21	6,1	Nastally	Capitalized no	Word capitalized.	Yes
310	21	10,3	Nastally	Added text " and reduce maintenance"	"and reduce maintenance" added where indicated.	Yes
311	21	14,2	Nastally	As a backup, with a toggle in SCADA to switch to it, this is ok.	Yes, the SCADA alternative is a backup.	Yes
312	21	15,2	Nastally	There is no recycled flow stream during storm events (when storm pumps are in service) because the sanitary pumps are shut down during storm pumping.	TM revised accordingly.	Yes

313	21	15,3	Nastally	See my notes above. This could be used with a hybrid calculation from 4.6 to make it work and give reliable influent flow data.	Included in Section 4.7.	Yes
314	21	17, Table 5-1	Nastally	Where is the transit time?	External and internal ultrasonic meter technologies are the transit time meters.	Yes
315	21	18,1	Nastally	What is required maintenance? What is expected up time? What is expected life? I wouldn't mind this if the answers above are good. I struggled with the current insertion meters and I don't want that unreliability again.	Required maintenance, expected up time, and expected lifespan are not certain at this time. Design team has discussed maintenance and reliability with the meter manufacturers and they recommend monitoring diagnostic parameters such as signal strength to improve maintenance efficiency (identify when sensor cleaning is needed). This will be coordinated with I&C in the BOD/detailed design and has been added to the TM in Sect 8 (Recommendations) and Sect 9 (Next Steps). There is no definitive answer on uptime and lifespan. As electronic devices the average lifespan of this type of meter is typically estimated around 10 years.	Yes
316	21	21,5	Nastally	I don't know that I agree. See above.	Reviewed during the workshop on 4/19/23. Added Table 5-2 to TM.	Yes
317	21	22,1	Nastally	Maybe...maybe not...need to discuss. If it's the cheapest, most reliable...I'm good. Need to have my questions answered.	Reviewed during the workshop on 4/19/23. No edit made to TM.	No
318	22	2, bullet 9	Nastally	This seems like it could spread the stream out sufficiently that it won't move solids. Is there a maximum depth of solids that this would be effective at? I imagine with the NWI diversion that after 1 event we may have significant solids down there.	As discussed at TM workshop 2, the flushing system physical modeling and associated analysis provides qualitative and relative comparisons. CDM Smith does not have an approximation of maximum debris depth for which the flushing would be effective. The spray angle will be evaluated further in the BOD phase coupled with number of nozzles.	No
319	22	11,2	Nastally	What is the condition of the existing 2" line?	No issues have been noted of the existing 2" header. Header will be field inspected to determine if in good enough condition for continued use and modifications. Included in TM Next Steps.	Yes

Comment No.	TM	Pg, Paragraph	Reviewer	Comment	Consultant Response	Incorporated in Final TM Deliverable
320	22	13,5	Nastally	These models need to be turned over to GLWA.	Acknowledged.	No
321	22	14,8	Nastally	Please provide videos and Clemson report.	Physical model study report was included as appendix to TM-15. Videos will be provided for baseline testing and flushing system operation.	No
322	22	18, bullet 6	Worth	This was a fairly loose sludge that could be waded through, heavy water content	Noted. Description of sludge characteristics added.	Yes
323	22	21,3	Nastally	Costs? How much time does the operator spend cleaning these areas? What are the chances of a flushing system being effective?	Project problem statement and interview with facility staff indicated that flushing of the facility required significant time after an event. The flushing system is not intended to replace the manual cleaning but rather decrease the time required for cleaning and to address the most common locations for sediment build-up (screening inlet channels).	No
324	22	25, Figure 4-7	Nastally	We have laser scans and this was the best picture we could come up with?	Figures have been updated in TM.	Yes
325	22	25,3	Nastally	Would running it while the basin is in service cause it to run out on its curve when the basin is full?	The pump curve for the conditioning pump model is fairly vertical, which allows for pumping over a wide range of basin levels. Final pump selection will confirm pump will not operate at run out.	No
326	22	27, 5	Nastally	Keep in mind that we don't really want to open up them in the drain vaults because then we pull all debris into the drain vault and create a big problem. Flushing should allow us to pull it into the surge chamber.	The proposed concept is to provide a connection that will allow debris to be flushed back into the basin. Once line is clear, debris and flushing water will be conveyed to the surge chamber.	No
327	24	2,bullet 3	Nastally	Put this on your list, but when we get to the design of this, we will need to coordinate with Jonathan Farrugia.	Noted. Next steps item in TM.	Yes
328	24	3, bullet 2	Nastally	bullets below should be sub-indented	Bullet formatting corrected	Yes
329	24	3, bullet 4	Nastally	confirm that this has not already been completed.	The ROW permitting has not been completed	No
330	24	9, 2	Nastally	Let's talk about this too as far as bid table...some of these items I want quantities and unit prices for in the bid...rather than just lump sum.	Noted, Next steps item: CDM Smith will discuss the bid table with GLWA team during design phase.	Yes

**AUTHORIZATION TO DISCHARGE UNDER THE
NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM**

In compliance with the provisions of the Federal Water Pollution Control Act, 33 U.S.C., Section 1251 *et seq.*, as amended; Part 31, Water Resources Protection, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA); Part 41, Sewerage Systems, of the NREPA; and Michigan Executive Order 2011-1,

City of Detroit Water and Sewerage Department

735 Randolph
Detroit, MI 48226

and

Great Lakes Water Authority

735 Randolph
Detroit, MI 48226

are authorized to discharge from the **Great Lakes Water Authority Water Resource Recovery Facility** located at

9300 W. Jefferson
Detroit, MI 48209

designated as **GLWA WRRF**

to the receiving water named the Detroit River and the Rouge River, and from combined sewer overflow facilities to the receiving waters named the Detroit River, the Rouge River, and Conner Creek in accordance with effluent limitations, monitoring requirements, and other conditions set forth in this permit.

This permit is based on a complete application submitted on March 29, 2017 and amended through May 25, 2017.

This permit takes effect on July 18, 2019. The provisions of this permit are severable. After notice and opportunity for a hearing, this permit may be modified, suspended, or revoked in whole or in part during its term in accordance with applicable laws and rules. On its effective date, this permit shall supersede National Pollutant Discharge Elimination System (NPDES) Permit No. MI0022802 (expiring October 1, 2017).

This permit and the authorization to discharge shall expire at midnight on **October 1, 2022**. In order to receive authorization to discharge beyond the date of expiration, the permittees shall submit an application that contains such information, forms, and fees as are required by the Michigan Department of Environment, Great Lakes, and Energy (Department) by **April 4, 2022**.

Issued: June 28, 2019. This permit was modified (minor) on July 18, 2019.

Original signed by Christine Alexander
Christine Alexander, Manager
Permits Section
Water Resources Division

PERMIT FEE REQUIREMENTS

In accordance with Section 324.3120 of the NREPA, the permittees shall make payment of an annual permit fee to the Department for each October 1 the permit is in effect regardless of occurrence of discharge. The permittees shall submit the fee in response to the Department's annual notice. The fee shall be postmarked by January 15 for notices mailed by December 1. The fee is due no later than 45 days after receiving the notice for notices mailed after December 1.

Annual Permit Fee Classification: Municipal Major, 500 MGD or greater (IP)

In accordance with Section 324.3132 of the NREPA, the permittees shall make payment of an annual biosolids land application fee to the Department if the permittees land applies biosolids. In response to the Department's annual notice, the permittees shall submit the fee, which shall be postmarked no later than January 31 of each year.

CONTACT INFORMATION

Unless specified otherwise, all contact with the Department required by this permit shall be made to the Southeast Michigan District Office of the Water Resources Division. The Southeast Michigan District Office is located at 27700 Donald Court, Warren, MI, 48092-2793, Telephone: 586-753-3700, Fax: 586-751-4690.

CONTESTED CASE INFORMATION

Any person who is aggrieved by this permit may file a sworn petition with the Michigan Administrative Hearing System within the Michigan Department of Licensing and Regulatory Affairs, c/o the Michigan Department of Environment, Great Lakes, and Energy, setting forth the conditions of the permit which are being challenged and specifying the grounds for the challenge. The Department of Licensing and Regulatory Affairs may reject any petition filed more than 60 days after issuance as being untimely.

PART I

Section A. Limitations and Monitoring Requirements

1. Effluent Limitations, Monitoring Point 049F

During the period beginning on the effective date of this permit and lasting until the expiration date of this permit, the permittees are authorized to discharge treated municipal wastewater from Monitoring Point 049F through Outfall 049 (DRO). Outfall 049 (DRO) discharges to the Detroit River. Such discharge shall be limited and monitored by the permittees as specified below.

Until the initiation of operation of the Rouge River Outfall (RRO) Disinfection Project, this discharge shall consist of secondary treated municipal wastewater and additional primary treated municipal wastewater up to the hydraulic capacity of Outfall 049 (DRO). After initiation of operation of the RRO Disinfection Project, this discharge shall consist of secondary treated municipal wastewater typically, but primary treated municipal wastewater and additional secondary treated municipal wastewater up to the hydraulic capacity of Outfall 049 (DRO) during wet weather events. During such wet weather events, the permittees are approved to discharge primary treated municipal wastewater from 049A thorough Outfall 049 (DRO).

Whenever Outfall 049 (DRO) is out of service for repairs, the permittees may discharge through Outfall 050 (RRO). All effluent authorized for discharge from Outfall 049F, and the monitoring, limitations and other requirements specified below shall apply to the discharge through Outfall 050 (RRO) unless otherwise specified. At least 10 days in advance of scheduled maintenance and within 24-hours after initiation of diversion due to emergency conditions, the permittees shall notify the Department of the reason for the diversion and the expected duration of the diversion.

The following design flow was used in determining the above limitations, but is not to be considered a limitation or actual capacity: a combined 930 MGD of secondary treated effluent.

- a. **Narrative Standard**
The receiving water shall contain no turbidity, color, oil films, floating solids, foams, settleable solids, or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.
- b. **Sampling Locations**
The sampling locations for the pollutants indicated in Part I.A.1. of this permit shall be representative of the effluent and consistent with the locations approved by the Department. The Department may approve alternate sampling locations that are demonstrated by the permittees to be representative of the effluent.
- c. **Quarterly Monitoring**
Quarterly samples shall be taken during the months of January, April, July, and October. If the facility does not discharge during these months, the permittees shall sample the next discharge occurring during the period in question. If the facility does not discharge during the period in question, a sample is not required for that period. For any month in which a sample is not taken, the permittees shall enter "*G" on the Discharge Monitoring Report (DMR).
- d. **Total Residual Chlorine (TRC)**
Compliance with the TRC limit shall be determined on the basis of one or more grab samples. If more than one (1) sample per day is taken, the additional samples shall be collected in near equal intervals over approximately eight (8) hours. The samples shall be analyzed immediately upon collection and the average reported as the daily concentration. Samples shall be analyzed in accordance with Part II.B.2. of this permit.
- e. **Monitoring Frequency Reduction for Perfluorooctane Sulfonate (PFOS) and/or Perfluorooctanoic Acid (PFOA)**
After the submittal of 24 months of data, the permittee may request, in writing, Department approval of a reduction in monitoring frequency for PFOS and/or PFOA. This request shall contain an explanation as to why the reduced monitoring is appropriate. Upon receipt of written approval and consistent with such approval, the permittee may reduce the monitoring frequency indicated in Part I.A.1. of this permit. The monitoring frequency for PFOS and/or PFOA, shall not be reduced to less than annually. The Department may revoke the approval for reduced monitoring at any time upon notification to the permittee.
- f. **Analytical Methods and Quantification Levels for Available Cyanide and Total Copper**
The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Available Cyanide shall be in accordance with EPA Method OIA-1677. The quantification level for Available Cyanide and Total Copper shall be 2.0 µg/l and 1.0 µg/l respectively unless a higher level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination. Upon approval from the

Department, the permittees may use alternate analytical methods (for parameters with methods specified in Title 40 of the Code of Federal Regulations (CFR), Part 136, the alternate methods are restricted to those listed in 40 CFR, Part 136).

- g. Limits Below the Quantification Level – Total Polychlorinated Biphenyls (PCBs)
The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Total PCBs shall be in accordance with EPA Method 608.3. Upon approval from the Department, the permittees may use alternate analytical methods (for parameters with methods specified in 40 CFR, Part 136, the alternate methods are restricted to those listed in 40 CFR, Part 136). The quantification level shall be 0.1 ug/l unless a higher level is appropriate because of sample matrix interference. Justification for a higher quantification level shall be submitted to the Department within 30 days of such determination.

The water quality-based effluent limitation for Total PCBs is 2.6×10^{-5} ug/l (2.0×10^{-4} lbs/day) maximum monthly average. This is less than the quantification level. Control requirements are therefore established consistent with R 323.1213. **The discharge of any individual aroclor at or above the quantification level of 0.1 ug/l is a specific violation of this permit.** If concentrations of all aroclors representing a monitoring period are less than their quantification levels, the permittees will be considered to be in compliance with the permit for the monitoring period that the analyses represent, provided that the permittees are also in full compliance with the Pollutant Minimization Program for Total PCBs set forth in Part I.A.10 of this permit. For the purpose of reporting on the Daily tab of the DMR, individual aroclor results less than the quantification level shall be reported as "<0.1." For the purpose of reporting on the Summary tab of the DMR, the value reported under PCB Aroclor shall be the highest aroclor concentration observed during the monitoring period. This permit condition does not authorize the discharge of PCBs at levels that are injurious to the designated uses of the waters of the state or that constitute a threat to the public health or welfare.

- h. Acute Toxicity Requirements
Test species shall include *Ceriodaphnia dubia*. Testing and reporting procedures shall follow procedures contained in EPA-821-R-02-012, "Methods for Measuring the Acute Toxicity of Effluents and Receiving Waters to Freshwater and Marine Organisms" (Fifth Edition). When the effluent ammonia nitrogen (as N) concentration is greater than 5 mg/l, the pH of the toxicity test shall be maintained at the pH of the effluent at the time of sample collection. The acute toxic unit (TU_A) value for **each species tested** shall be reported on the DMR. For **each species not tested**, the permittees shall enter **"*W"** on the DMR. Completed toxicity test reports for each test conducted shall be retained by the permittees in accordance with the requirements of Part II.B.5. of this permit and shall be available for review by the Department upon request. Toxicity test data acceptability is contingent upon the validation of the test method by the testing laboratory. Such validation shall be submitted to the Department upon request.

The Department will review the toxicity data submitted by the permittees to determine if the acute toxicity requirements of R 323.1219 are being satisfied.

1) If the data indicate persistent exceedance of the acute toxicity requirements of R 323.1219, upon written notification by the Department, the following conditions apply. Within 90 days of the above notification, the permittees shall implement a Toxicity Reduction Evaluation (TRE). The objective of the TRE shall be to reduce the toxicity of the final effluent from Monitoring Point 049F to <3.0 TU_A within three (3) years of notification. The following documents are available as guidance to reduce toxicity to acceptable levels: Phase I, EPA/600/6-91/003; Phase II, EPA/600/R-92/080; Phase III, EPA/600/R-92/081; and Publicly Owned Treatment Works, EPA/833B-99/002. The tests shall be conducted and reported as specified above. Upon approval from the Department, the acute toxicity tests may be performed using the more sensitive species identified in the acute toxicity database. If a more sensitive species cannot be identified, the acute toxicity tests shall be performed with both species. Annual progress reports shall be submitted to the Department within 30 days of the completion of the last test of each annual cycle.

2) This permit may be modified in accordance with applicable laws and rules to include additional whole effluent toxicity control requirements as necessary.

2. Effluent Limitations, Monitoring Point 049A

During the period beginning on the effective date of this permit and lasting until the expiration date of this permit, the permittees are approved to discharge treated municipal wastewater and treated storm water runoff from Monitoring Point 049A through Outfall 049 (DRO). Outfall 049 (DRO) discharges to the Detroit River. Such discharge shall be limited and monitored by the GLWA as specified below.

Monitoring Point 049A is a primary treated effluent conduit. There shall be no discharge from Monitoring Point 049A directly to the Detroit River through Outfall 049 (DRO) unless the discharge from Monitoring Point 049B exceeds a peak hourly flow of 930 MGD (which includes recycle) or in accordance with an approved GLWA Wet Weather Operational Plan (see Part I.A.11.). Discharges from Monitoring Point 049A shall be limited and monitored by the permittees as specified below.

<u>Parameter</u>	<u>Maximum Limits for Quantity or Loading</u>			<u>Maximum Limits for Quality or Concentration</u>			<u>Monitoring Frequency</u>	<u>Sample Type</u>
	<u>Monthly</u>	<u>Daily</u>	<u>Units</u>	<u>Monthly</u>	<u>Daily</u>	<u>Units</u>

	<u>12-Month Rolling Average</u>			<u>12-Month Rolling Average</u>				
Total Mercury	0.19	---	lbs/day	25	---	ng/l	Monthly	Calculation

- a. Sampling Locations
The sampling locations for the pollutants in Part 1.A.2. of this permit shall be representative of the effluent and consistent with the locations approved by the Department. Samples for CBOD₅, Total Suspended Solids, Ammonia Nitrogen, Total Mercury, and Total Phosphorus shall be taken prior to mixing with other waste streams. The Department may approve alternate sampling locations that are demonstrated by the permittees to be representative of the effluent
- b. Sampling of Short-Term Wet Weather Events
If the first calendar day of the discharge event through Monitoring Point 049A includes less than three hours of flow but continues into the next calendar day, the sampling can be included as a part of the subsequent event the following day.
- c. Final Effluent Limitation for Total Mercury
The final limit for total mercury is the Discharge Specific Level Currently Achievable (LCA) based on a multiple discharger variance from the WQBEL of 1.3 ng/l, pursuant to Rule 1103(9) of the Water Quality Standards. Compliance with the LCA shall be determined as a 12-month rolling average, the calculation of which may be done using blank-corrected sample results. The 12-month rolling average shall be determined by adding the present monthly average result to the preceding 11 monthly average results then dividing the sum by 12. For facilities with quarterly monitoring requirements for total mercury, quarterly monitoring shall be equivalent to three (3) months of monitoring in calculating the

12-month rolling average. Facilities that monitor more frequently than monthly for total mercury must determine the monthly average result, which is the sum of the results of all data obtained in a given month divided by the total number of samples taken, in order to calculate the 12-month rolling average. If the 12-month rolling average for any month is less than or equal to the LCA, the GLWA will be considered to be in compliance for total mercury for that month, provided the GLWA is also in full compliance with the Pollutant Minimization Program for Total Mercury, set forth in Part I.A.10. of this permit.

The permittee may choose to demonstrate that an alternate site-specific LCA is appropriate and request a permit modification. Such request and supporting documentation shall be submitted in writing to the Department. Supporting documentation shall include a minimum of 12 samples taken over 12-month period in accordance with EPA Method 1631. Upon approval, this permit may be modified in accordance with applicable laws and rules to incorporate the alternate site-specific LCA as the effluent limitation for Total Mercury.

After a minimum of 12 monthly data points have been collected, the permittees may request a reduction in the monitoring frequency for total mercury. This request shall contain an explanation as to why the reduced monitoring is appropriate and shall be submitted to the Department. Upon receipt of written approval and consistent with such approval, the permittees may reduce the monitoring frequency for total mercury indicated in Part I.A.2. of this permit. The Department may revoke the approval for reduced monitoring at any time upon notification to the permittees.

d. Total Mercury Testing and Additional Reporting Requirements

The analytical protocol for total mercury shall be in accordance with EPA Method 1631, Revision E, "Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Fluorescence Spectrometry." The quantification level for total mercury shall be 0.5 ng/l, unless a higher level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination.

The use of clean technique sampling procedures is required unless the permittees can demonstrate to the Department that an alternate sampling procedure is representative of the discharge. Guidance for clean technique sampling is contained in EPA Method 1669, Sampling Ambient Water for Trace Metals at EPA Water Quality Criteria Levels (Sampling Guidance), EPA-821-R96-001, July 1996. Information and data documenting the permittee's sampling and analytical protocols and data acceptability shall be submitted to the Department upon request.

In order to demonstrate compliance with EPA Method 1631E and EPA Method 1669, the permittees shall report, on the daily sheet, the analytical results of all field blanks and field duplicates collected in conjunction with each sampling event, as well as laboratory method blanks when used for blank correction. The permittees shall collect at least one (1) field blank and at least one (1) field duplicate per sampling event. If more than ten (10) samples are collected during a sampling event, the permittees shall collect at least one (1) additional field blank AND field duplicate for every ten (10) samples collected. Only field blanks or laboratory method blanks may be used to calculate a concentration lower than the actual sample analytical results (i.e., a blank correction). Only one (1) blank (field OR laboratory method) may be used for blank correction of a given sample result, and only if the blank meets the quality control acceptance criteria. If blank correction is not performed on a given sample analytical result, the permittees shall report under "Total Mercury – Corrected" the same value reported under "Total Mercury – Uncorrected." The field duplicate is for quality control purposes only; its analytical result shall not be averaged with the sample result.

3. Effluent Limitations, Monitoring Point 049B

During the period beginning on the effective date of this permit and lasting until the expiration date of this permit, the permittees are authorized to discharge treated municipal wastewater from Monitoring Point 049B through Outfall 049 (DRO), or through Outfall 050 (RRO) when there is reduced hydraulic capacity through DRO or during wet weather, once the RRO Disinfection Project is completed. Outfall 049 (DRO) discharges to the Detroit River. Outfall 050 (RRO) discharges to the Rouge River. In addition, the permittees are authorized to discharge treated municipal wastewater from Monitoring Point 049B through Outfall 050 to the Rouge River as provided in Part I.A.4.

Outfall 049B is the combined secondary treated effluent conduit for all dry weather flows and all wet weather flows up to and including a peak hourly flow of 930 MGD (which includes recycle).

Discharges from Monitoring Point 049B shall be limited and monitored by the permittees as specified below.

Parameter	Maximum Limits for Quantity or Loading				Maximum Limits for Quality or Concentration				Monitoring Frequency	Sample Type
	Monthly	7-Day	Daily	Units	Monthly	7-Day	Daily	Units		
Flow (This flow measurement is all secondary flow minus recycle and buffer flows)	(report)	---	(report)	MGD	---	---	---	---	Daily	Report Total Daily Flow
Recycled Flow (Screened Final Effluent)	(report)	---	(report)	MGD	---	---	---	---	Daily	Report Total Daily SFE Flow

				Minimum Monthly					
CBOD ₅ Minimum % Removal	---	---	---	85	---	(report)	%	Monthly	Calculation
Total Suspended Solids Minimum % Removal			---	85	---	(report)	%	Monthly	Calculation

- a. **Sampling Locations**
Samples for CBOD₅, Total Suspended Solids, Ammonia Nitrogen, Total Phosphorus, Total Mercury and pH shall be taken prior to mixing with other waste streams. Samples for pH shall be collected only during periods of discharge from Monitoring Point 049A through Outfall 049 (DRO).
- b. **Percent Removal Requirements**
These requirements shall be calculated based on the monthly (30-day) effluent CBOD₅ and TSS concentrations and the monthly influent concentrations for approximately the same period.
- c. **Total Phosphorus Six Month Average Limit (April - September)**
The six month average shall be determined by adding the six monthly average results from April through September and dividing the sum by six. For the purpose of reporting on the Discharge Monitoring Reports, the permittees shall calculate and report the six month average on the October Discharge Monitoring Report.
- d. **Quarterly Monitoring**
Quarterly samples shall be taken during the months of January, April, July, and October. If the facility does not discharge during these months, the permittee shall sample the next discharge occurring during the period in question. If the facility does not discharge during the period in question, a sample is not required for that period. For any month in which a sample is not taken, the permittee shall enter "*G" on the Discharge Monitoring Report (DMR). (For purposes of reporting on the Daily tab of the DMR, the permittee shall enter "*G" on the first day of the month only).
- e. **Final Effluent Limitation for Total Mercury**
The final limit for total mercury is the Discharge Specific Level Currently Achievable (LCA) based on a multiple discharger variance from the WQBEL of 1.3 ng/l, pursuant to Rule 1103(9) of the Water Quality Standards. Compliance with the LCA shall be determined as a 12-month rolling average, the calculation of which may be done using blank-corrected sample results. The 12-month rolling average shall be determined by adding the present monthly average result to the preceding 11 monthly average results then dividing the sum by 12. For facilities with quarterly monitoring requirements for total mercury, quarterly monitoring shall be equivalent to three (3) months of monitoring in calculating the 12-month rolling average. Facilities that monitor more frequently than monthly for total mercury must determine the monthly average result, which is the sum of the results of all data obtained in a given month divided by the total number of samples taken, in order to calculate the 12-month rolling average. If the 12-month rolling average for any month is less than or equal to the LCA, the permittees will be considered to be in compliance for total mercury for that month, provided the permittees are also in full compliance with the Pollutant Minimization Program for Total Mercury, set forth in Part I.A.10. of this permit.

The permittee may choose to demonstrate that an alternate site-specific LCA is appropriate and request a permit modification. Such request and supporting documentation shall be submitted in writing to the Department. Supporting documentation shall include a minimum of 12 samples taken over 12-month period in accordance with EPA Method 1631. Upon approval, this permit may be modified in accordance with applicable laws and rules to incorporate the alternate site-specific LCA as the effluent limitation for Total Mercury.

After a minimum of 12 monthly data points have been collected, the permittees may request a reduction in the monitoring frequency for total mercury. This request shall contain an explanation as to why the reduced monitoring is appropriate and shall be submitted to the Department. Upon receipt of written approval and consistent with such approval, the permittees may reduce the monitoring frequency for total mercury indicated in Part I.A.3. of this permit. The Department may revoke the approval for reduced monitoring at any time upon notification to the permittees.

f. Total Mercury Testing and Additional Reporting Requirements

The analytical protocol for total mercury shall be in accordance with EPA Method 1631, Revision E, "Mercury in Water by Oxidation, Purge and Trap, and Cold Vapor Atomic Fluorescence Spectrometry." The quantification level for total mercury shall be 0.5 ng/l, unless a higher level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination.

The use of clean technique sampling procedures is required unless the permittees can demonstrate to the Department that an alternate sampling procedure is representative of the discharge. Guidance for clean technique sampling is contained in EPA Method 1669, Sampling Ambient Water for Trace Metals at EPA Water Quality Criteria Levels (Sampling Guidance), EPA-821-R96-001, July 1996. Information and data documenting the permittee's sampling and analytical protocols and data acceptability shall be submitted to the Department upon request.

In order to demonstrate compliance with EPA Method 1631E and EPA Method 1669, the permittees shall report, on the daily sheet, the analytical results of all field blanks and field duplicates collected in conjunction with each sampling event, as well as laboratory method blanks when used for blank correction. The permittees shall collect at least one (1) field blank and at least one (1) field duplicate per sampling event. If more than ten (10) samples are collected during a sampling event, the permittees shall collect at least one (1) additional field blank AND field duplicate for every ten (10) samples collected. Only field blanks or laboratory method blanks may be used to calculate a concentration lower than the actual sample analytical results (i.e., a blank correction). Only one (1) blank (field OR laboratory method) may be used for blank correction of a given sample result, and only if the blank meets the quality control acceptance criteria. If blank correction is not performed on a given sample analytical result, the permittees shall report under "Total Mercury – Corrected" the same value reported under "Total Mercury – Uncorrected." The field duplicate is for quality control purposes only; its analytical result shall not be averaged with the sample result.

4. Interim Effluent Limitations, Monitoring Point 050A

During the period beginning on the effective date of this permit and lasting until initiation of operation of the RRO Disinfection Project, the permittees are approved to discharge treated municipal wastewater and treated storm water runoff from Monitoring Point 050A through Outfall 050 (RRO). Normally, the discharge may consist of only primary treated effluent when the discharge is necessary due to hydraulic constraints resulting from wet weather events. There shall be no discharge from Monitoring Point 050A unless the discharge from Monitoring Point 049B exceeds a peak hourly flow of 930 MGD (which includes recycle) or in accordance with an approved GLWA WRRF Wet Weather Operational Plan (see Part I.A.11.). Discharge from Outfall 050 (RRO) is not allowed unless hydraulically or structurally necessary. Outfall 050 (RRO) discharges to the Rouge River.

Other options for discharge from Outfall 050 include, 1) when Outfall 049 (DRO) is out-of-service, the discharge may consist of secondary or secondary and primary treated wastewater, 2) when Outfall 049 (DRO) has reduced hydraulic capacity the discharge may consist of secondary or secondary and primary treated wastewater, and 3) when there is department approved limited secondary capacity when Outfall 049 cannot be used due to construction, the discharge may consist of secondary or secondary and primary treated wastewater. Discharges from Monitoring Point 050A shall be limited and monitored by the permittees as specified below.

Parameter	Maximum Limits for Quantity or Loading				Maximum Limits for Quality or Concentration				Monitoring Frequency	Sample Type
	Monthly	7-Day	Daily	Units	Monthly	7-Day	Daily	Units		

Limitations and monitoring requirements in effect when Outfall 049 is out-of-service and prior to initiation of operation of the RRO Disinfection Project:

All limitations and monitoring specified in Part I.A.1. apply except for the Available Cyanide monitoring requirement, Total Residual Chlorine requirement, and the Fecal Coliform Bacteria limitations, which are replaced with the limitations and monitoring requirements specified below with the Total Residual Chlorine monitoring and limitation removed:

Available Cyanide	---	---	---	---	---	---	89	µg/l	Daily	Grab
Fecal Coliform Bacteria	---	---	---	---	(report)	(report)	---	cts/100 ml	Daily	Grab

- a. Sampling of Short-Term Wet Weather Events
If the first calendar day of the discharge event through Monitoring Point 050A includes less than three hours of flow but continues into the next calendar day, the sampling can be included as a part of the subsequent event the following day.

4. Interim Effluent Limitations, Monitoring Point 050A (continued)

Parameter	Maximum Limits for Quantity or Loading				Maximum Limits for Quality or Concentration				Monitoring Frequency	Sample Type
	Monthly	7-Day	Daily	Units	Monthly	7-Day	Daily	Units		
Limitations and monitoring requirements in effect during other periods of discharge from Monitoring Point 050A and prior to Initiation of operation of the RRO Disinfection Project:										
Flow	(report)	---	(report)	MGD	---	---	---	---	Daily	Report Total Daily Flow

- a. Narrative Standard
The receiving water shall contain no turbidity, color, oil films, floating solids, foams, settleable solids, or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.

- b. **Sampling Locations**
The sampling locations for the pollutants in Part 1.A.4. of this permit shall be representative of the effluent and consistent with the locations approved by the Department. The Department may approve alternate sampling locations that are demonstrated by the GLWA to be representative of the effluent.
- c. **Sampling of Short-Term Wet Weather Events**
If the first calendar day of the discharge event through Monitoring Point 050A includes less than three hours of flow but continues into the next calendar day, the sampling can be included as a part of the subsequent event the following day.
- d. **Analytical Methods and Quantification Levels for Available Cyanide and Total Copper**
The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Available Cyanide shall be in accordance with EPA Method OIA-1677. The quantification levels for Available Cyanide and Total Copper shall be 2.0 µg/l and 1.0 µg/l respectively unless a higher level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination. Upon approval of the Department, the permittees may use alternate analytical methods (for parameters with methods specified in 40 CFR 136, the alternate methods are restricted to those listed in 40 CFR 136).
- e. **Limits Below the Quantification Level – Total Polychlorinated Biphenyls (PCBs)** The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Total PCBs shall be in accordance with EPA Method 608.3. Upon approval from the Department, the permittees may use alternate analytical methods (for parameters with methods specified in 40 CFR, Part 136, the alternate methods are restricted to those listed in 40 CFR, Part 136). The quantification level shall be 0.1 ug/l unless a higher level is appropriate because of sample matrix interference. Justification for a higher quantification level shall be submitted to the Department within 30 days of such determination.

For the purpose of reporting on the Daily tab of the DMR, individual aroclor results less than the quantification level shall be reported as "<0.1." For the purpose of reporting on the Summary tab of the DMR, the value reported under PCB Aroclor shall be the highest individual aroclor concentration observed during the monitoring period. This permit condition does not authorize the discharge of PCBs at levels that are injurious to the designated uses of the waters of the state or that constitute a threat to the public health or welfare.

5. Final Effluent Limitations, Monitoring Point 050A

Upon initiation of operation of the RRO Disinfection Project, the permittees are approved to discharge secondary treated municipal wastewater and primary treated municipal wastewater when hydraulically necessary from Monitoring Point 050A through Outfall 050 (RRO). Outfall 050 (RRO) discharges to the Rouge River. Discharge from Outfall 050 (RRO) is approved when the hydraulic capacity of Outfall 049 (DRO) is not sufficient to meet the approved GLWA wet weather operational plan (see Part I.A.11.). Such discharge shall be limited and monitored by the permittees as specified below.

<u>Parameter</u>	<u>Maximum Limits for Quantity or Loading</u>				<u>Maximum Limits for Quality or Concentration</u>				<u>Monitoring Frequency</u>	<u>Sample Type</u>
	<u>Monthly</u>	<u>7-Day</u>	<u>Daily</u>	<u>Units</u>	<u>Monthly</u>	<u>7-Day</u>	<u>Daily</u>	<u>Units</u>

PCB Aroclor 1016	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1221	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1232	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1242	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1248	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1254	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
PCB Aroclor 1260	---	---	---	---	---	---	(report)	µg/l	Weekly	24-Hr Composite
Maximum PCB Aroclor										
PCB Aroclor (See I.A.5.f.)	---	---	---	---	<0.1	---	---	µg/l	Monthly	See I.A.5.f.
Minimum Daily Maximum Daily										
pH	---	---	---	---	6.0	---	9.0	S.U.	Daily	
Dissolved Oxygen	---	---	---	---	3.0	---	---	mg/l	Daily	Grab

- a. Narrative Standard
The receiving water shall contain no turbidity, color, oil films, floating solids, foams, settleable solids, suspended solids, or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.
- b. Sampling Locations
The sampling locations for the pollutants in Part I.A.5. of this permit shall be representative of the effluent and consistent with the locations approved by the Department. The Department may approve alternate sampling locations that are demonstrated by the permittees to be representative of the effluent.
- c. Sampling of Short-Term Wet Weather Events
If the first calendar day of the discharge event includes less than three hours of flow but continues into the next calendar day, the sampling can be included as part of the subsequent event the following day.

- d. Total Residual Chlorine (TRC)
Compliance with the TRC limit shall be determined on the basis of one or more grab samples. If more than one (1) sample per day is taken, the additional samples shall be collected in near equal intervals over approximately eight (8) hours. The samples shall be analyzed immediately upon collection and the average reported as the daily concentration. Samples shall be analyzed in accordance with Part II.B.2. of this permit.
- e. Analytical Methods and Quantification Levels for Available Cyanide and Total Copper
The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Available Cyanide shall be in accordance with EPA Method OIA-1677. The quantification levels for Available Cyanide and Total Copper shall be 2.0 µg/l and 1.0 µg/l, respectively, unless a higher level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination. Upon approval of the Department, the permittees may use alternate analytical methods (for parameters with methods specified in 40 CFR 136, the alternate methods are restricted to those listed in 40 CFR 136).
- f. Limits Below the Quantification Level – Total Polychlorinated Biphenyls (PCBs)
The sampling procedures, preservation and handling, and analytical protocol for compliance monitoring for Total PCBs shall be in accordance with EPA Method 608.3. Upon approval from the Department, the permittees may use alternate analytical methods (for parameters with methods specified in 40 CFR, Part 136, the alternate methods are restricted to those listed in 40 CFR, Part 136). The quantification level shall be 0.1 ug/l unless a higher level is appropriate because of sample matrix interference. Justification for a higher quantification level shall be submitted to the Department within 30 days of such determination.

The water quality-based effluent limitation for Total PCBs is 2.6×10^{-5} µg/l (2.0×10^{-4} lbs/day) maximum monthly average. This is less than the quantification level. Control requirements are therefore established consistent with R 323.1213. **The discharge of any individual aroclor at or above the quantification level of 0.1 ug/l is a specific violation of this permit.** If concentrations of all aroclors representing a monitoring period are less than their quantification levels, the permittees will be considered to be in compliance with the permit for the monitoring period that the analyses represent, provided that the permittees are also in full compliance with the Pollutant Minimization Program for Total PCBs set forth in Part I.A.10 of this permit. For the purpose of reporting on the Daily tab of the DMR, individual aroclor results less than the quantification level shall be reported as "<0.1." For the purpose of reporting on the Summary tab of the DMR, the value reported under PCB Aroclor shall be the highest aroclor concentration observed during the monitoring period. This permit condition does not authorize the discharge of PCBs at levels that are injurious to the designated uses of the waters of the state or that constitute a threat to the public health or welfare.

- g. Schedule of Implementation
The permittees shall implement the following for Outfall 050 (RRO) Disinfection Program:
- 1) On or before February 1, 2010 (submitted), the permittees shall submit for review and approval a basis of design report for the previously proposed Outfall 084 (RRO2).
 - 2) On or before March 1, 2011 (submitted), the permittees shall submit for review and approval complete plans and specifications for Segment 1 of the previously proposed Outfall 084 (RRO2) project. Segment 1 consists of improvements undertaken at the WRRF consistent with the approved Basis of Design report.
 - 3) On or before July 1, 2012 (submitted), the permittees shall commence construction of Segment 1, consistent with the approved plans and specifications.
 - 4) On or before July 1, 2013 (submitted), the permittees shall submit a construction progress report for Segment 1 of the previously proposed Outfall 084 (RRO2).
 - 5) On or before March 1, 2015, (completed) the permittees shall complete construction of Segment 1 of the previously proposed Outfall 084 (RRO2) project.

- 6) On or before June 1, 2016, (submitted) the permittees shall submit for review and approval a complete basis of design report, and complete plans and specifications, for the Outfall 050 (RRO) Disinfection Project (if design, bid, build). Alternatively, if DWSD chooses to pursue design-build for the Outfall 050 (RRO) Disinfection Project, DWSD shall submit on or before June 1, 2016, (submitted) a detailed engineering report for the overall project, a permitting plan (that includes a description of the construction segments), a timetable for Part 41 permit application submittal, and sufficient project schematics for the overall project.
- 7) On or before November 1, 2016, (completed) the permittees shall submit complete plans and specifications for at a minimum the first segment to be construction under a design-build contract.
- 8) On or before April 1, 2017, (commenced) the permittees shall commence construction of the RRO Disinfection Project, consistent with the approved plans and specifications.
- 9) On or before April 1, 2018, (submitted) the permittees shall submit a construction progress report for RRO Disinfection Project.
- 10) On or before April 1, 2019, (completed) the permittees shall complete construction of RRO Disinfection Project and place into full operation the facilities to achieve final effluent limits specified in Part I.A.5.

6. Combined Sewer Overflow Retention Treatment Basin Discharge Authorization, Monitoring Points 101A, 102A, 103A, 104A, 108A and 109A

During the period beginning on the effective date of this permit and lasting until the expiration date of this permit, the permittees are authorized to discharge treated combined sewage from the Hubbell/Southfield Combined Sewer Overflow (CSO) Retention Treatment Basin (RTB), Monitoring Point 101A, through Outfall 101; from the Puritan/Fenkell CSO RTB, Monitoring Point 102A, through Outfall 102; from the Seven Mile CSO RTB, Monitoring Point 103A, through Outfall 103; from the Belle Isle RTB, Monitoring Point 108A, through Outfall 108; from the Oakwood RTB, Monitoring Point 109A, through Outfall 109; and from the Conner Creek CSO RTB Monitoring Point 104A, through Outfall 104 when the basins are full and wastewater flows exceed downstream interceptor capacity. Outfall 101, Outfall 102, Outfall 103, and Outfall 109 discharge to the Rouge River. Outfall 108 discharges to the Detroit River. Outfall 104 discharges to Conner Creek. Such discharges shall be limited and monitored by the permittees as specified below:

Influent Characteristics	Maximum Limits for Quantity or Loading				Maximum Limits for Quality or Concentration				Monitoring Frequency	Sample Type
	Monthly	7-Day	Daily	Units	Monthly	7-Day	Event	Units		
Flow	(report)	---	(report)	MGD	---	---	---	---	Daily	Report Total Daily Flow

Dissolved Oxygen	---	---	---	---	(report)	---	---	mg/l	Daily During Discharge	Grab

a. Retention Basin Monitoring and Reporting

The permittee shall conduct retention basin monitoring and report consistent with the requirements of Part II.C.2. of this permit. The permittee shall supply the results of each sample analyzed during each discharge period.

An Event starts when combined sewage is discharged into a facility, and ends when effluent flow (if any) ceases and does not resume within 24 hours.

Influent flow shall be reported for all wet weather events where combined sewage is discharged into the facility. Influent flow reporting shall also indicate the component of the total influent flow that is dewatered to the interceptor from the facility during an event and shall be reported in the comment section of the monthly Discharge Monitoring Reports (DMR). Alternate procedures may be approved by the Department.

Effluent flow shall be reported for all events that cause discharge from the facility to the receiving waters.

Effluent sampling for CBOD₅, TSS, Ammonia Nitrogen (as N), and Total Phosphorus (as P) shall be by effluent flow-weighted composite sampling over the entire event. Alternate procedures for determining an event composite may be approved by the Department if existing equipment cannot reliably determine a flow-weighted composite. For purposes of reporting for a discharge event that occurs on multiple calendar days, the composite pollutant concentrations for the event shall be reported on the day the discharge event ended. Individual events shall be determined by a lack of effluent discharge for 24 hours.

For **effluent pH**, report the maximum value of any individual sample taken during the month in the "Maximum" column under "Quality or Concentration" on the monthly DMRs and the minimum value of any individual sample taken during the month in the "Minimum" column under "Quality or Concentration" on the monthly DMRs. The individual values taken during the month shall be reported on the daily DMRs.

For **effluent dissolved oxygen**, report the lowest concentration of any individual sample in the "Minimum" column under the "Quantity or Concentration" on the monthly DMRs. The individual values taken during the month shall be reported on the daily DMRs.

For **effluent Fecal Coliform Bacteria and Total Residual Chlorine**, grab samples shall be collected every two (2) hours for the first six (6) hours of the discharge and every four (4) hours thereafter for the duration of the discharge; the first sample shall be collected as soon as practical after the discharge begins. For fecal coliform, the "event maximum" shall be reported on the daily DMRs as the geometric mean of all samples taken during an event, provided that three (3) or more samples are collected. For TRC, report the average of all samples in an event as the "Event Average" and the maximum individual sample in an event as the "Event Maximum" on the daily DMRs. The goal of the effluent sampling program is to collect at least three samples during each discharge event, and samples shall be collected at shorter intervals at the onset of the event, if the permittee estimates that the event duration may be less than six hours. For purposes of reporting for a discharge event that occurs on multiple calendar days, the pollutant concentrations for the event shall be reported on the day the discharge event ended. The highest event averages for Fecal Coliform and TRC shall also be reported in the "Maximum" columns under "Quality and Concentration" on the monthly DMRs.

b. Retention Treatment Basin Dewatering

The retention treatment basin shall be promptly dewatered as in accordance with the Department Approved Consolidated Annual Report following the need to divert flow to the basin and shall be maintained in readiness for use. The discharge of sludge or residual accumulations from the basin to the surface waters is prohibited. These sludges shall be promptly removed and disposed in accordance with procedures approved by the Department.

For this permit while the Regional Operational Plan is being revised, if up to 930 MGD (including recycle) is being processed with secondary treatment at the WRRF and no primary flow is being discharged, then tributary combined or sanitary storage basins in the GLWA system may be dewatered. Such dewatering will not be considered a violation of this permit, even if contrary to the Wet Weather Event definition (see Part II.A.). Once a revised Regional Operation Plan is developed, it shall be implemented once reviewed and approved by the Department.

c. Narrative Standard

The receiving water shall contain no turbidity, color, oil films, floating solids, foams, settleable solids, or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.

d. Operation and Maintenance Plan

The permittee shall assure that discharges only occur in response to rainfall (or snowmelt) events and cease soon thereafter. Any rehabilitation and maintenance needs shall be addressed to ensure adequate sewer capacity and functionality. This may be accomplished through continued implementation of the approved Operation and Maintenance Plan.

7. Combined Sewer Overflow Screening and Disinfection Facilities Discharge Authorization, Monitoring Points 105A, 106A and 107A

During the period beginning on the effective date of this permit and lasting until the expiration date of this permit, the permittees are authorized to discharge treated combined sewage from the Leib Combined Sewer Overflow (CSO) Screening and Disinfection Facility Monitoring Point 105A through Outfall 105, from the St. Aubin CSO Screening and Disinfection Facility Monitoring Point 106A through Outfall 106, and from the Baby Creek CSO Screening and Disinfection Facility Monitoring Point 107A through Outfall 107 when the wastewater flows exceed downstream interceptor capacities. Outfall 105 and Outfall 106 discharge to the Detroit River. Outfall 107 discharges to the Rouge River. Such discharges shall be limited and monitored by the permittees as specified below:

Effluent Characteristics	Maximum Limits for Quantity or Loading				Maximum Limits for Quality or Concentration				Monitoring Frequency	Sample Type
	Monthly	7-Day	Daily	Units	Monthly	7-Day	Daily	Units		
Flow	(report)	---	(report)	MGD	---	---	---	---	Daily	Report Total Daily Flow
Carbonaceous Biochemical Oxygen Demand (CBOD ₅)	---	---	---	---	(report)	---	(report)	mg/l	Quarterly	Grab
Total Suspended Solids	---	---	---	---	(report)	---	(report)	mg/l	Quarterly	Grab
Ammonia Nitrogen (as N)	---	---	---	---	(report)	---	(report)	mg/l	Quarterly	Grab
Total Phosphorus (as P)	---	---	---	---	(report)	---	(report)	mg/l	Quarterly	Grab

Dissolved Oxygen	---	---	---	---	(report)	---	---	mg/l	Daily During Discharge	Grab

- a. Screening and Disinfection Facilities Monitoring and Reporting
The permittees shall monitor screening and disinfection facilities performance and report the monitoring consistent with the requirements of Part II.C.2. of this permit. The permittees shall supply the results of each sample taken during each discharge period.

Effluent flow shall be reported for all events that cause discharge from the facility to the receiving waters.

For **effluent pH**, report the maximum value of any individual sample taken during the month in the "Maximum" column under "Quality or Concentration" on the monthly DMRs and the minimum value of any individual sample taken during the month in the "Minimum" column under "Quality or Concentration" on the monthly DMRs. The individual values taken during the month shall be reported on the daily DMRs.

For **effluent dissolved oxygen**, report the lowest concentration of any individual sample in the "Minimum" column under the "Quantity or Concentration" on the monthly DMRs. The individual values taken during the month shall be reported on the daily DMRs.

For **effluent Fecal Coliform Bacteria and Total Residual Chlorine**, grab samples shall be collected every two (2) hours for the first six (6) hours of the discharge and every four (4) hours thereafter for the duration of the discharge; the first sample shall be collected as soon as practical after the discharge begins. For fecal coliform, the "event maximum" shall be reported on the daily DMRs as the geometric mean of all samples taken during an event, provided that three (3) or more samples are collected. For TRC, report the average of all samples in an event as the "Event Average" and the maximum individual sample in an event as the "Event Maximum" on the daily DMRs. The goal of the effluent sampling program is to collect at least three samples during each discharge event, and samples shall be collected at shorter intervals at the onset of the event, if the permittees estimate that the event duration may be less than six hours. For purposes of reporting for a discharge event that occurs on multiple calendar days, the pollutant concentrations for the event shall be reported on the day the discharge event ended. The highest event averages for Fecal Coliform and TRC shall also be reported in the "Maximum" columns under "Quality and Concentration" on the monthly DMRs.

b. **Narrative Standard**

The receiving water shall contain no turbidity, color, oil films, floating solids, foams, settleable solids, or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.

Consider for Leib screen evaluation

c. **Sampling Locations**

The sampling locations for the pollutants indicated in Part I.A.7 of this permit shall be representative of the effluent and consistent with the locations approved by the Department.

d. **Operation and Maintenance Plan**

The permittees shall assure that discharges only occur in response to rainfall (or snowmelt) events and cease soon thereafter. Any rehabilitation and maintenance needs shall be addressed to ensure adequate sewer capacity and functionality. This may be accomplished through continued implementation of the approved Operation and Maintenance Plan.

e. **Treatment Facility Dewatering**

The treatment facility shall be promptly dewatered (if applicable) in accordance with the Department Approved Consolidated Annual Report possible following the need to divert flow to the facility and shall be maintained in readiness for use. The discharge of sludge or residual accumulations from the facility to the surface waters is prohibited.

For this permit while the Regional Operational Plan is being revised, if up to 930 MGD (including recycle) is being processed with secondary treatment at the WRRF and no primary flow is being discharged, then tributary combined or sanitary storage basins in the GLWA system may be dewatered. Such dewatering will not be considered a violation of this permit, even if contrary to the Wet Weather Event definition (see Part II.A). Once a revised Regional Operation Plan is developed, it shall be implemented once reviewed and approved by the Department.

f. **Quarterly Monitoring**

Quarterly samples shall be taken during the months of January, April, July, and October. If the facility does not discharge during these months, the permittee shall sample the next discharge occurring during the period in question. If the facility does not discharge during the period in question, a sample is not required for that period. For any month in which a sample is not taken, the permittee shall enter "*G" on the Discharge Monitoring Report (DMR). (For purposes of reporting on the Daily tab of the DMR, the permittee shall enter "*G" on the first day of the month only).

8. Total Residual Chlorine Minimization Program

Section 8. Applies to all the CSO facilities

The goal of the Total Residual Chlorine (TRC) Minimization Program is operate the CSO RTBs and the CSO screening and disinfection facilities in a manner that will provide consistent, effective disinfection while minimizing the discharge of TRC, recognizing the overall goal is compliance with the TRC Final Acute Value of 0.038 mg/l at any point in the receiving stream, unless it is determined by the Department by a permit action that a higher level is acceptable.

In addition, the Operational Goals for this facility are 1.5 mg/l TRC as an event average value and 2.0 mg/l (November – April) or 3.0 mg/l (May – October) TRC as an event instantaneous maximum value.

- a. TRC Minimization Assessment (Assessment) (submitted)  These were completed by CDM Smith as a sub to METCO. (Oakwood was not included in the report)
- The permittees shall prepare and conduct a program to assess the capability of each of the 5 CSO RTBs and screening and disinfection facilities as agreed to (a subset of those listed in Part I.A.6. and Part I.A.7.), to minimize the discharge of TRC. Each Assessment shall be conducted according to a schedule acceptable to the Department. Compliance with the Fecal Coliform Bacteria effluent limits set forth in Part I.A.6. and Part I.A.7. of this permit shall be maintained during each Assessment. Each Assessment shall include an evaluation of various operational practices under a variety of wet weather events to identify measures which can be taken to reduce TRC discharge concentrations. Upon notification by the Department, the permittees shall begin conducting each Assessment over an 18-month period and shall submit a report summarizing the results to the Department within 60 days of completion. An extension of an Assessment period beyond 18 months may be requested by the permittees for approval by the Department in the event that a sufficient number of CSO discharge events have not occurred to allow for an adequate assessment of operational procedures.

Each Assessment report shall include the expected achievable TRC discharge concentrations, recommendations as to specific protocols to be used to manage sodium hypochlorite (NaOCl) dosage rates under various conditions to achieve the Operational Goals, and recommended facility modifications to enhance the ability to control TRC levels while maintaining compliance with the Fecal Coliform Bacteria limits. Specific procedures for adjustment of NaOCl feed rates to minimize the discharge of TRC shall be submitted as part of the Operational Plan (and revised as appropriate in annual updates), as required by Part I.A.15.e. of this permit. The TRC minimization procedures, developed as part of each Assessment, shall be implemented upon approval by the Department.

- b. Operational Goals
- Upon completion of each Assessment, the permittees shall operate the facility with a goal of 1.5 mg/l TRC as an event average value and a goal of 2.0 mg/l (November – April) or 3.0 mg/l (May – October) TRC as an event instantaneous maximum value. If upon completion of an Assessment, the permittees determine the facility can achieve lower TRC goals than those specified above, then the permittees shall operate the facility to achieve the lower TRC levels. If either TRC goal is exceeded for a CSO discharge event, the permittees shall submit a written report to the Department within seven (7) days explaining the cause of the exceedance and describing the corrective measures that will be undertaken to prevent a future recurrence.

- c. In-Stream TRC Effluent Plume Evaluation (submitted)  These were completed by CDM Smith as a sub to Hinshon Environmental Co. (preceded Ed Hogan, Wade Trim as .compliance consultant)
- The permittees shall conduct an evaluation of the in-stream TRC effluent plume attributable to each of the agreed-to 5 CSO RTBs screening and disinfection facility discharges. The evaluation shall identify the location and size of the TRC effluent plume during and after CSO discharge events and identify the maximum TRC concentrations in-stream at various downstream locations. Upon notification by the Department to begin conducting each Assessment (Part I.A.8.a.), the permittees shall have 60 days to submit a TRC effluent plume work plan describing the proposed evaluation including sampling locations and a proposed implementation schedule such that the In-Stream TRC Effluent Plume Evaluation shall occur after completion of each Assessment and when the operational goals begin. The permittees shall implement the In-Stream TRC Effluent Plume Evaluation following the schedule upon Department approval of the TRC effluent plume work plan. The permittees shall submit a report documenting the results of the TRC Effluent Plume Evaluation within 90 days after completion of the field work.

- d. Permit Re-Opener Clause
- Upon completion of each TRC Minimization Assessment and each In-Stream TRC Effluent Plume Evaluation, the Department may reevaluate the need for TRC effluent limitations. This permit may be

modified in accordance with applicable laws and rules to incorporate such revisions as may be necessary to comply with Water Quality Standards at the time of discharge.

- e. Best Management Practices/Operator Coordination Work Group (Work Group)
The permittees shall attend and participate in at least quarterly Work Group meetings with representatives from other CSO facilities in Southeast Michigan to exchange information and share experiences relating to the operation and maintenance of CSO control facilities. Such Work Group meetings shall be used to develop Best Management Practices (BMPs) relating to CSO RTB operation, with an initial focus on actions to minimize the TRC discharge levels. At a minimum, the Work Group shall include representatives of the following CSO facilities: Birmingham CSO RTB, Bloomfield Village CSO RTB, Dearborn CSO, GLWA WRRF CSO Facilities, Inkster-Dearborn Heights CSO, Oakland County-Acacia Park (Acacia Park CSO Drainage District, Village of Beverly Hills, City of Birmingham), Redford Township CSO, River Rouge CSO, Wayne County – Dearborn Heights CSO, Wayne County – Inkster CSO, Wayne County – Inkster – Dearborn Heights CSO, and Wayne County – Redford – Livonia CSO. The Work Group shall submit an annual report summarizing the meetings and BMPs developed to the Department by March 1st of each year.

9. Additional Monitoring Requirements This applies to WRRF Outfalls (Not CSOs)

As a condition of this permit, the permittees shall monitor the discharge from monitoring points 049F and 050A for the constituents identified below. This monitoring is an application requirement of 40 CFR 122.21(j), effective December 2, 1999. Testing shall be conducted in October 2019, May 2020, March 2021, and August 2021. Grab samples shall be collected for total phenols, and the Volatile Organic Compounds identified below. For all other parameters, 24-hour composite samples shall be collected.

Test species for whole effluent toxicity monitoring shall include fathead minnow **and** *Ceriodaphnia dubia*. If the permittees have received Department approval to conduct chronic toxicity testing using the more sensitive species identified in the toxicity database, the first three (3) tests required above may be performed using the more sensitive species. The last (4th) test shall be conducted using both species. Testing and reporting procedures shall follow procedures contained in EPA-821-R-02-013, "Short-term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms" (Fourth Edition). When the effluent ammonia nitrogen (as N) concentration is greater than 3 mg/l, the pH of the toxicity test shall be maintained at a pH of 8 Standard Units. Acute and chronic toxicity data shall be included in the reporting for the toxicity test results. Toxicity test data acceptability is contingent upon the validation of the test method by the testing laboratory. Such validation shall be submitted to the Department upon request.

For selected parameters required under this section, the maximum acceptable quantification levels and analytical methods shall be as specified under Quantification Levels and Analytical Methods for Selected Parameters, below, unless a higher quantification level is appropriate because of sample matrix interference. Justification for higher quantification levels shall be submitted to the Department within 30 days of such determination.

The results of such additional monitoring shall be submitted with the application for reissuance (see the cover page of this permit for the application due date). The permittees shall notify the Department within 14 days of completing the monitoring for each month specified above in accordance with Part II.C.5. Additional reporting requirements are specified in Part II.C.11. The permittees shall report to the Department any whole effluent toxicity test results greater than 1.0 TU_A or 1.0 TU_C within five (5) days of becoming aware of the result. If, upon review of the analysis, it is determined that additional requirements are needed to protect the receiving waters in accordance with applicable water quality standards, the permit may then be modified by the Department in accordance with applicable laws and rules.

10. Pollutant Minimization Program for Total Mercury and PCBs

The goal of the Pollutant Minimization Program is to maintain the effluent concentration of total mercury at or below 1.3 ng/l and the final effluent limitations for Total Polychlorinated Biphenyls (PCBs). The permittees shall continue to implement the Pollutant Minimization Program approved on November 9, 1995, and updated in October, 1996, and modifications thereto, to proceed toward the goal. The Pollutant Minimization Program includes the following:

- an annual review and semi-annual monitoring of potential sources of mercury and PCBs entering the wastewater collection system, including wet weather sources such as runoff/contributions from contaminated sites in the collection area;
- a program for quarterly monitoring of influent and periodic monitoring of sludge for mercury and PCBs; and
- implementation of reasonable cost-effective control measures when sources of mercury and/or PCBs are discovered. Factors to be considered include significance of sources, economic considerations, and technical and treatability considerations.

On or before October 1st of each year, the permittees shall submit a status report for the previous calendar year to the Department that includes 1) the monitoring results for the previous year, 2) an updated list of potential mercury and/or PCB sources, and 3) a summary of all actions taken to reduce or eliminate identified sources of mercury and/or PCBs.

Any information generated as a result of the Pollutant Minimization Program set forth in this permit may be used to support a request to modify the approved program or to demonstrate that the Pollutant Minimization Program requirement has been completed satisfactorily.

A request for modification of the approved program and supporting documentation shall be submitted in writing to the Department for review and approval. The Department may approve modifications to the approved program (approval of a program modification does not require a permit modification), including a reduction in the frequency of the requirements under items a. and b.

This permit may be modified in accordance with applicable laws and rules to include additional mercury and/or PCB conditions and/or limitations as necessary.

11. Water Resource Recovery Facility Wet Weather Operational Plan

The approved Water Resource Recovery Facility Wet Weather Operational Plan provides the protocol for operations during the interim period before full completion of the Long-term CSO Control Plan. This plan details the necessary requirements to maximize wet weather treatment at the WRRF, while complying with effluent limits and all other conditions of this permit, and minimizing untreated combined sewage discharges in the tributary collection system.

The GLWA WRRF Wet Weather Operational Plan shall be coordinated with the Collection System and CSO Treatment Facilities Operational Plan that is required in accordance with Part I.A.15.d. of this permit. Annually, on or before April 1st, the permittees shall submit an update of the Water Resource Recovery Facility Wet Weather Operational Plan in conjunction with the Collection System and CSO Treatment Facilities Operational Plan update as part of the Consolidated Annual Report to the Department for review and approval.

12. Facilities Improvement Program

The permittees shall continue to meet the sludge dewatering, conveyance, and final disposal requirements; submit and implement the solids disposal plans; correct the alum sludge issue; submit the WRRF shutdown schedules; and develop and implement the asset management program as detailed below.

a. WRRF Solids Processing Requirements and Corrections

- 1) Capacity for sludge dewatering, conveyance, and final disposal; Required maximum solids inventory loads.

The permittees shall ensure that sludge dewatering equipment, sludge conveyance equipment, and final sludge disposal capability is available at the GLWA WRRF as follows:

- a) The permittees shall ensure that the WRRF sludge dewatering equipment, sludge conveyance equipment, and final sludge disposal capability are maintained for use; and in good operational working order to meet the following requirements:
- (1) Average capacity of 500 dry tons per day (dtpd), calculated as a calendar monthly average;
 - (2) Peak capacity of 850 dtpd, calculated as a 10-day average;
 - (3) The peak 10-day average shall be available during any wet weather event when the WRRF is operated in the "Storm Period" of the currently approved WRRF Wet Weather Operational Plan as required by Part I.A.11.

The permittees shall also:

- (4) Notify the Department within one business day if solids are recycled from the gravity thickeners to the head of the WRRF for more than 72 hours and provide an explanation for the recycled solids. Recycled solids are defined as a TSS overflow concentration of 1000 mg/l or greater from Complex A thickeners;
- (5) Maintain a monthly average solids inventory of less than 750 dtpd, when there are less than 5 days of discharge from Outfall 049A during the month, and maintain a calendar quarterly average solids inventory not to exceed 1000 dtpd. Solids inventory is defined as the total solids in gravity thickener complexes A and B, determined daily in dtpd;
- (6) This Section will be reviewed during the next NPDES reissuance based on WRRF performance; and
- (7) The permittees are allowed to submit to the Department for review and approval a request to modify the numerical levels specified in Part I.A.12.a. of this permit. This modification request shall include supporting rationale for the revised numerical levels.

2) Long-Term Solids Disposal Plan

- a) The permittees submitted to the Department for review and approval a Long-Term Solids Disposal Plan (LTSDP). This Solids Disposal Plan is designed to ensure the availability of sufficient sludge dewatering equipment and sludge disposal capability to meet the capacity requirements specified in Parts I.A.12.a.1).a).(1)&(2) of this permit. The permittees shall implement the LTSDP in accordance with the following schedule:

- (1) On or before December 31, 2018, (submitted) the permittees shall submit for approval, a disposal plan for 250 dtpd. This requirement is based on the LTSDP approved on September 24, 2013. Upon notification from the Department, the permittees shall implement the approved disposal plan;
- (2) On or before December 31, 2025, the permittees shall complete implementation of the approved plan referenced in item (1) above;

- b) The GLWA are advised that implementation of individual elements of the LTSDP may require Part 41 wastewater construction permits or may require other Department approvals.

3) Alum Sludge Correction

The permittees shall continue to implement the approved plan to correct the solids dewatering concerns at the WRRF due to alum sludge discharges from GLWA water treatment plants (WTPs) into the collection system.

Annually, on or before September 1st the permittees shall submit a report to the Department describing if the implemented plan continued to meet the conditions specified above for the preceding fiscal year (July 1 – June 30).

Part 41 construction permits at the WRRF and/or Act 399 construction permits at the specific WTPs may be needed depending on the components of the approved plan.

b. WRRF Quarterly Shutdown Schedules

On or before December 1, March 1, June 1, and September 1, the permittees shall submit quarterly WRRF Shutdown Schedules, until notified in writing by the Department. Consistent with the quarterly dates indicated above, these schedules shall be submitted to the Department in a mutually agreeable format one month prior to the start of each calendar quarter for review and approval. Each quarterly schedule shall detail the primary treatment capacity, secondary treatment capacity, and sludge processing capacity that is planned to be available during the upcoming quarter, considering coordinated shutdowns necessary to complete all rehabilitation and other projects. The shutdown schedules shall be proposed to minimize environmental impact and maximize available treatment during construction of all projects, consistent with the requirements of the rules associated with Act 451, Part 41, being 299.2943 and 299.2955(1) and (3).

c. Operation, Maintenance & Replacement/Asset Management

The permittees shall at all times properly operate and maintain all facilities (i.e., sewer system, treatment works, as defined in Part 41 of Act 451, 1994 as amended, and control systems) that are installed or used by the permittees to operate the treatment works and sewer system and achieve and maintain compliance with the conditions of this permit. The requirements of an asset management program contain goals of effective performance, adequate funding, and adequate operator staffing and training. Asset management is a planning process focused on gaining optimum value for each asset and providing the financial resources to rehabilitate and replace them when necessary; Asset management is centered on a framework of five (5) core elements: the current state of the assets, the required sustainable level of service, the assets critical to sustained performance, the best-value life-cycle costs, and the best long-term funding strategy.

- 1) The permittees shall continue to implement the approved Asset Management Program that addresses the following items:

- A comprehensive fixed asset inventory that is maintained, managed, and updated within a computerized maintenance management system (CMMS),

- A comprehensive inventory of the collection system fixed assets and collection system map,
- A Preventive Maintenance Program that may include predictive and reliability centered maintenance,
- A Needs Assessment updated every five years as part of the Project Plan (due on or before October 1, 2021), including condition assessment and evaluation of service level,
- An assessment of asset criticality and risk management,
- A capital planning process,
- A Scheduled Replacement Program (SRP) for assets,
- Monitoring and periodic performance evaluation through Key Performance Indicators (KPIs),
- Management oversight of system performance.

The permittees' Asset Management Program submitted on January 1, 2014, was approved on January 14, 2014, and substantially revised on September 29, 2017.

2) An Annual Report covering implementation of the Asset Management Program during the prior Fiscal Year (July 1 – June 30) shall be prepared by the permittees and submitted to the Department on or before October 1st. The Annual Report shall include:

- a) A description and evaluation of the sufficiency of the staffing levels maintained during the year,
- b) A description and evaluation of the sufficiency and adequacy of inspections and maintenance activities conducted and corrective actions taken during the previous year,
- c) Expenditures for collection system maintenance activities, treatment works maintenance activities, corrective actions, and capital investment during the previous year, compared with budgeted/projected expenditures, including an evaluation of the sufficiency of expenditures,
- d) A summary of asset/areas identified for inspection/action (including capital improvement) in the upcoming year based on the five (5) core elements and the criticality and risk analysis,
- e) A maintenance budget and capital improvement budget for the upcoming year, based on implementation of an effective asset management program that meets the five (5) core elements,
- f) An updated estimate of the revenue necessary to complete anticipated OM&R activities, the associated rate schedule impact, and an assessment of the adequacy of the revenue to perform necessary OM&R work, and
- g) A description of the progress made towards completion of the outstanding tasks as described in the previous year's Asset Management Annual Report and an updated schedule for completion of any outstanding tasks.

d. Staffing Plan

A Staffing Plan, as required by ACO-00131, has been approved by the Department. The GLWA shall provide an adequate staffing level, in accordance with the approved Staffing Plan, to carry out the operation, maintenance, repair, and testing functions required to ensure compliance with the terms and conditions of this permit. During the term of ACO-00131, a change in the minimum staffing level may be requested by the GLWA by submittal of a revised Staffing Plan, including training requirements, and may be revised only by mutual agreement in writing between the GLWA and the Department. Should ACO-00131 be terminated, then the staffing plan shall be updated as required by the Operations and Maintenance Manual (Part II.C.14 of this permit), and an up to date copy of the manual shall be kept at the WRRF. The Department may review the manual in whole or in part (i.e. staffing) at their discretion and require modifications to it if portions are determined to be inadequate.

- e. Key Performance Indicator Monthly Report
The permittee shall update the Key Performance Indicator (KPI) report monthly. If Administrative Consent Order No. ACO-000131, as amended, is terminated, the KPI report shall be submitted by the last day of the month following the termination of the ACO.
- f. Public Participation
The permittees will participate in Department initiated public outreach meetings during the term of this permit as resources allow and provided there is adequate notification by the Department.

13. Reopener for Primary and Secondary Treatment Capacity

The permittees are required to maintain a wet weather primary treatment capacity of 1700 MGD (raw) and wet weather secondary treatment capacity of 930 MGD (which includes recycle). When the elevation of the influent wet well is greater than 85 feet and the facility is not pumping at 1700 MGD (raw), the discharge from untreated combined sewage overflow (CSO) upstream of the facility are not authorized, unless caused by localized storm conditions.

These required wet weather treatment capacities may be revised if new/altered wet weather conditions (such as initiation of operation of upstream CSO facilities, etc.) indicate that either less or more flow can be effectively processed. The criteria used to determine whether the required wet weather primary treatment capacities should be revised must include additional plant evaluation under the updated conditions, using testing procedures approved by the Department.

For reference, outfall/monitoring point designations are shown on the following diagrams:

Prior to Initiation of Operation of RRO Disinfection Project

After Initiation of Operation of RRO Disinfection Project

14. Outfalls Prohibited from Discharge to Combined Sewer System

The following Outfalls are prohibited from discharge except as provided for in Part II.C.9.:

<u>OUTFALL</u>	<u>LOCATION</u>	<u>LAT/LONG</u>	<u>RECEIVING STREAM</u>
004	Fairview (DWF) Pump Station (P28 through P31) Parkview & Detroit River - Emergency only	42°21'20" 082°58'01"	Discharge to Detroit River (Stop-logged)
014	Dubois (B12) Dubois & Detroit River	42°20'01" 083°01'19"	Detroit River
051	Carbon (B46) Carbon & Rouge River	42°17'07" 083°08'17"	Rouge River
054	Fort St. (DWSD Northwest) Interceptor) (B50) South Fort St. & Rouge River (West Shore)	42°17'25" 083°08'35"	Rouge River
056	Fort St. (Oakwood District) (B49) South Fort St. & Rouge River (West Shore)	42°17'27" 083°08'33"	Rouge River
080	Fox Creek Backwater Gates (B01) East Jefferson & Fox Creek.	42°22'28" 082°56'27"	Fox Creek to Detroit River

The permittees shall provide for ongoing monitoring (Flow, Duration) for these outfalls should they discharge. This monitoring shall be used to comply with the requirements of Section 324.3112(a) of The Michigan Act (See Part I.A.16.).

15. Discharges from Combined Sewer System

a. Limited Discharge Authorization

The permittees are required to utilize, to the maximum extent practicable, available sewerage system transportation capabilities for the delivery of combined sewage to treatment facilities. For an interim period during which the amended Long-Term CSO Control Plan is to be implemented, the permittees are authorized to discharge during wet weather events (see Part II.A.) combined sewage from the outfalls and locations listed below in accordance with the following conditions:

- 1) a flow rate equivalent to the peak dry weather flow rate has been conveyed to the secondary treatment facilities for treatment without bypass,
- 2) the total sewerage system storage and transportation capacity for conveyance of wet weather flows to the treatment facilities for treatment has been utilized within the hydraulic design constraints of the system,
- 3) all primary treatment plant capacity and secondary treatment plant capacity has been utilized in accordance with the approved WRRF Wet Weather Operation Plan (Part 1.A.11.), unless a storm event is localized to the extent that the hydraulic capacity of a portion of the collection system (considering storage) is exceeded prior to reaching plant capacities, and
- 4) the permittees are in full compliance with all requirements as set forth in Part I.A.16. Combined Sewer Overflow discharges to the Rouge River, the Detroit River, and the Old Channel of the Rouge River are authorized until prohibited, eliminated, or adequately treated to meet water quality standards at times of discharge in accordance with the requirements below, and as specified in Part 1.A.15.f. and g.
- 5) the outfalls that immediately follow this paragraph are included in the Limited Discharge Authorization. There are some untreated CSO outfalls that appear to discharge only during extreme events. Extreme is defined as; (a) no more than one untreated discharge in ten years from a CSO outfall during the April 1 through October 31 growth period, (b) modeled to not discharge at the 25 year – 24 hour event (during growth period, with normal soil moisture, rainfall distributed to a SCS Type II distribution), or (c) monitored to occur only at rainfalls greater than 4 inches in a 24 hour period. The Department does not intend to require construction of treatment facilities at the following outfalls should they continue to only discharge at the extreme event. This addresses CSO outfalls consistently with SSO outfalls according to the 2002 SSO Policy and 2003 Clarification Statement. The list of untreated CSO outfalls that only discharge at the extreme event is flexible and may be adjusted with the adaptive management CSO correction program.

<u>OUTFALL</u>	<u>LOCATION</u>	<u>LAT/LONG</u>	<u>RECEIVING STREAM</u>
029	Rosa Parks (B27) Rosa Parks & Detroit River	42°19'13" 083°03'56"	Detroit River
030	Vermont (B28) Vermont (extended) & Detroit River	42°19'06" 083°04'09"	Detroit River
037	McKinstry (B35) McKinstry & Detroit River	42°18'19" 083°05'13"	Detroit River
042	Campbell (B40) Campbell & Detroit River	42°18'01" 083°05'30"	Detroit River
048	Pulaski (B59A &B) Pulaski & Rouge River	42°17'21" 083°07'11"	Old Channel Rouge River

6) the outfalls that immediately follow this paragraph are also included in the Limited Discharge Authorization. There are some untreated CSOs that appear to discharge at a minimal frequency and volume. Minimal discharge is defined as actual monitoring of a volume less than 0.3 MG of discharge over a five year period. The Department does not intend to require construction of treatment facilities at the following outfalls should they continue to only discharge at this minimal frequency and volume. The list of untreated CSO outfalls that only discharge at a minimal frequency and volume is flexible and may be adjusted with the adaptive management CSO correction program.

<u>OUTFALL</u>	<u>LOCATION</u>	<u>LAT/LONG</u>	<u>RECEIVING STREAM</u>
024	Griswold (B22) Griswold & Detroit River	42°19'35" 083°02'28"	Detroit River

Nothing in this section of the permit shall be construed to limit the State of Michigan's ability to pursue remedies under the Michigan Act.

- b. **Qualified Operations and Maintenance Manager for CSO Discharges**
The permittees shall place the wastewater collection system under the supervision of a qualified Operations and Maintenance Manager who shall serve as the contact person for the Department regarding combined sewer discharges. The permittees may replace the manager at any time and shall notify the Department within ten days after the replacement.
- c. **Disconnection of Eaves Troughs and Roof Downspouts**
The permittees shall eliminate direct connections of eaves troughs and roof downspouts to the sewer system throughout the service area tributary to the Upper Rouge CSO outfalls (Outfalls 059-069, 072-075, 077, and 079). This requirement shall be completed for residential property and commercial and industrial properties or as approved by the Department consistent with the permittees' implementation of the Green Storm Water Infrastructure program. In addition, the permittees shall eliminate direct connections of eave troughs and roof downspouts in the service areas tributary to the CSO RTBs, to the CSO Screening & Disinfection Facilities, and to the remaining untreated CSOs based upon the plan detailed in the revised Long-term Control Program. This requirement does not apply if the permittees demonstrates that the disconnection of eaves troughs and roof downspouts is not a cost-effective means of reducing the frequency or duration of combined sewer overflows or of maintaining compliance with this permit. Such a demonstration and supporting documentation shall be submitted to the Department for approval.
- d. **Collection System and CSO Treatment Facilities Operational Plan**
The permittees shall continue implementation of the approved Collection System and CSO Treatment Facilities Operational Plan (Operational Plan). The implementation of the Operational Plan shall be coordinated with the WRRF Wet Weather Operational Plan that is required for development and implementation in accordance with Part I.A.11. of this permit.

On or before April 1 (annually), the permittees shall submit a revised Operational Plan for Department review and approval, which incorporates all changes made to the plan during the last calendar year (items 1-12 below), and supplies the annual discharge documentation (item 13 below). Any changes to the Operational Plan that affect the rate, volume, or characteristics of the discharge, or the system

storage and transportation for conveyance of wet weather flows, shall be submitted to the Department and approved prior to implementation. The operational plan shall define the hydraulic design constraints of the system during both dry and wet weather operation.

The plan shall include:

- 1) the procedures utilized at the permittees' CSO RTBs and Screening & Disinfection Facilities for adjustment of NaOCl disinfectant feed rates to minimize the discharge of total residual chlorine,
- 2) the procedures and schedule for sampling/monitoring the stored NaOCl disinfectant at the permittees' CSO RTBs and Screening & Disinfection Facilities to determine the concentration of available chlorine and assure that the stored NaOCl is of sufficient strength to provide effective disinfection,
- 3) the procedures for sampling/monitoring the available chlorine concentration of each load of NaOCl delivered to the permittees' CSO RTBs and Screening & Disinfection Facilities,
- 4) if applicable, the procedures utilized at the permittees' CSO RTBs and Screening & Disinfection Facilities for adjustment of dehalogenating reagent feed rates to minimize the discharge of excess reagent,
- 5) the procedures to ensure that the collection and treatment systems are operated to maximize treatment,
- 6) the procedures to ensure that all dry weather flows are conveyed to the treatment facilities for treatment without bypass,
- 7) the hydraulic profile and hydraulic operational elevations for system pump stations, regulators, diversion devices, gates, level sensors, interceptors, etc., to ensure the conveyance of all dry weather flows to the treatment facilities for treatment without bypass,
- 8) the procedures to ensure that the sewerage system hydraulic and storage capacity is identified and fully utilized during wet weather events with eventual treatment of stored flows,
- 9) the procedures to ensure that the greatest quantity of wet weather flow is conveyed to the treatment facilities for treatment to minimize untreated wastewater discharges within the region tributary to the GLWA WRRF,
- 10) the hydraulic profile and hydraulic operational elevations for system pump stations, regulators, diversion devices, gates, level sensors, interceptors, etc., to ensure that the greatest quantity of wet weather flow is conveyed to the treatment facilities for treatment to minimize combined sewage discharges,
- 11) the procedures for ongoing inspection of the sewer system within the permittees' jurisdiction for excessive inflow and infiltration and, where necessary, reduction of the excessive infiltration and inflow sources, and the elimination of unauthorized sewer system connections, and
- 12) identification of the location of the rain gauges.
- 13) The permittees shall submit annual reports that supply the documentation of rainfall and the frequency, duration, and volume of all discharge events during the previous 12-month period (from January 1st through December 31st of the previous year).

The permittees shall continue to pursue the coordination of operational plans (Regional Operational Plan) with tributary communities with the intent of maximizing flow conveyance to the GLWA system and minimizing regional CSOs. Once the Regional Operational Plan is approved by the Department, it shall be implemented.

e. New Wastewater Flows

Increased levels of discharge of sanitary sewage from the combined sewer overflow outfalls listed in Part I.A.15.a. of this permit, the CSO RTBs (see Part I.A.6. of this permit), and the CSO Screening and Disinfection Facilities (see Part I.A.7. of this permit) are prohibited unless:

- 1) the increased discharges are the result of new sanitary wastewater flows which, on the basis of sound professional judgment, are within design peak dry weather transportation capacity, or
- 2) the permittees have officially adopted and are timely implementing a definite program, satisfactory to the Department, leading to the construction and operation of necessary collection, transportation, or treatment devices.

f. CSO Control Projects This is related to uncontrolled CSO Outfalls and not pertinent to the CSO treatment facilities.1) Pertinent CSO Program History

The permittees are continuing to implement CSO Control Programs for the various CSO outfalls that discharge to the Rouge River and the Detroit River. Depending upon the particular CSO Control Program and outfall, the permittees are required to provide for the prohibition, elimination, or adequate treatment of combined sewage discharges containing raw sewage, to comply with the Water Quality Standards at times of discharge.

For the CSO outfalls discharging to the Rouge River, the development and implementation of the CSO Control Programs for the various outfalls was initially established based upon the goals of the Rouge River Remedial Action Plan (RAP), which called for a phased approach to solving the water quality problems of the river. Phase I of the Rouge River RAP extended to 1993 and included 1) monitoring and optimization of the existing combined sewer system, 2) detailed local planning for CSO controls and 3) resolution of financing and institutional problems. Phase II of the Rouge River RAP extended to 2005 (2012 for a few limited outfalls) and called for facility construction based on the goal of protection of public health through the elimination of raw sewage discharges and the control of toxic pollutants. Phase III of the Rouge River RAP follows completion of Phase II facilities and includes further improvements, if necessary, to comply with water quality standards at the time of discharge. Due to the demonstrated financial capability of the permittees for City of Detroit residents in 2009, 2012 and 2017, the CSO Control Program for the CSOs discharging to the Rouge River has been revised as reflected below.

For the CSO outfalls discharging to the Detroit River and the Old Channel of the Rouge River, Department approval of the CSO Control Programs is determined on a case-by-case basis with considerations for environmental impacts, public health impacts, technical feasibility, and economic affordability. As was the case for the Rouge River program, the demonstrated financial capability of the permittees for City of Detroit residents in 2009, 2012 and 2017 also affected the CSO Control Program for the Detroit River and the Old Channel of the Rouge River, and has been revised as reflected below.

In addition, the CSO Control Program now includes significant Green Storm water Infrastructure (GSI) requirements that are an important component of the approved Long-Term CSO Control Program.

Previous Long-Term CSO Control Program Documents include:

- Original Long-Term CSO Control Plan (1996)
- Long-Term CSO Control Plan Update (2002)
- Amendment Rouge (2008)
- Amendment Detroit (2008)
- Evaluation of CSO Control Alternative (for the Upper Rouge Outfalls) (December 15, 2009)

- Supplemental Report on Alternative CSO Controls for the Upper Rouge Outfalls) (April 30, 2010)

The implementation and completion of the CSO Control Program indicated in Part I.A.15.f. and g. are a necessary and essential requirement of this permit.

2) CSO Correction Program Moving Forward

The permittees shall control remaining combined sewer discharges, that are not classified as either extreme or minimal (see Part 1.A.15.a.5) & 6)), to eliminate the discharges or provide adequate treatment of the combined sewage discharges to comply with Water Quality Standards at times of discharge. Upon completion of the RRO disinfection project at the GLWA WRRF and commencing final use of Outfall 050A, the permittees will have completed core elements of their CSO control program and will have achieved a very high level of CSO control. It has been determined that this core level of control has routinely achieved adequate treatment of 95% of the annual combined sewer volume to the collection system. While additional CSO control measures are needed to fully comply with Michigan's Water Quality Standards, as the permittees moves into the final phases of the CSO control program it is appropriate to plan and schedule the remaining control measures, taking into account what has been put in place to date and lessons learned, the unique technical and financial situation of the city of Detroit, and the nature of the remaining CSO challenges.

Based on the foregoing, the permittees shall proceed with remaining CSO corrections using an adaptive management approach. This means that as new information is gained from: (1) evaluation of existing CSO projects and new treatment technologies, (2) evaluation of real-time collection system controls, (3) more accurate and complete data on CSO discharge frequency and volume, (4) benefits of less flow to the collection system from green storm water infrastructure (GSI), (5) benefits of less flow to the collection system due to the City's drainage charge program and new storm water ordinance, (6) benefits of less flow to the collection system as the City continues its sewer rehabilitation program, and (7) any other pertinent information, future CSO controls can be adapted to best provide cost-effective elimination of discharges, adequate treatment of discharges, or classification of discharges as minimal or extreme. Note that for purposes of designing CSO correction projects, minimal discharge is defined as less than 0.3 MG of discharge over a five year period, and extreme is defined as; (a) no more than one untreated discharge in ten years from a CSO outfall during the April 1 through October 31 growth period, (b) modeled to not discharge at the 25 year – 24 hour event (during growth period, with normal soil moisture, rainfall distributed to a SCS Type II distribution), or (c) monitored to occur only at rainfalls greater than 4 inches in a 24 hour period. The performance standard can be based on actual monitoring data normalized for a typical and representative 10-year period of rainfall record or predictively determined based on a calibrated and verified continuous model using a typical and representative 10-year period of rainfall record or other method as determined acceptable by the Department.

The permittees shall propose the non-core CSO correction projects to be designed, constructed, and operated to provide CSO elimination or adequate treatment during the subsequent five-year permit cycle, with each permit reapplication beginning in April 2022. High priority non-core outfalls should generally be addressed first, and outfalls thought of as high priority can change at any time due to implementation of the adaptive management approach. City of Detroit residents within the DWSD service area are "high burden" status based on sewer fees paid as a percentage of median annual household income. Planning of CSO control measures may reflect the permittees' financial capacity for City of Detroit residents determined in the Financial Capability Evaluation that is submitted with each permit reapplication. Based on current and projected CSO capital revenue requirements, and the current average cost per Detroit household for wastewater treatment and CSO control as a percentage of Detroit median household income, the Department does not expect the permittees to propose non-core CSO correction projects with this permit. The permittees shall next propose non-core CSO correction projects for review and approval with the permit reapplication required by April 4, 2022 (and then on April 4, 2027, and April 4, 2032). However, this first tier of non-core projects during 2023 through 2027 is expected to be relatively low cost. Discussion between the permittees and the Department have determined that low cost projects can include connection of CSO discharges to existing CSO treatment facilities, limited storage projects based on the performance standard with no disinfection, outfall gates and in-system storage projects, increased regulator flow capacity, separation projects that use smaller sanitary pipes in existing larger combined sewers to carry sanitary sewage to

GLWA interceptors while the existing combined sewer becomes a storm sewer, and others. At each application submittal in 2022, 2027, and 2032, the project proposal shall include an updated Financial Capability Evaluation that may also include other financial factors as appropriate. Reissued permits will then be drafted and issued with schedules for approved CSO correction projects that provide continuing progress toward meeting water quality standards. The permittees shall prepare an evaluation of Financial Capability, consistent with state and federal guidance, and shall submit the evaluation with the applications for reissuance of this permit (see the cover page of this permit for the next application due date). The Financial Capability Report shall be in the form of previous reports utilizing the EPA Financial Capability Guidance Document (USEPA 832-B-97-004; February, 1997), and updated with information as may be available in order to assess the permittees' ability to undertake future capital improvement projects related to the Long-Term CSO Control Program. This permit may be modified in accordance with applicable law and rules to incorporate revisions to conform to pertinent laws or rules, or as necessary to address prevailing situations.

Based on information currently available, the following are lists by water body that are high priority CSOs that require control. These outfalls can be revised at any time by the permittees or the Department, reflecting adaptive management considerations. While either the permittees or Department can propose changes at any time, an agreement between the two parties is required and shall be made in writing. The goal will be to complete projects fully addressing all high priority outfalls before October 1, 2037.

Rouge River non-core CSOs (these can be changed by mutual agreement between the permittees and the Department)

High Priority Outfalls
059, 061, 064, 065, 074

Detroit River non-core CSOs (these can be changed by mutual agreement between the permittees and the Department)

High Priority Outfalls
005, 007, 009, 012, 022, 025, 031, 038

3) Adaptive Management Program for this Permit

The adaptive management approach for this permit, before beginning relatively low cost CSO correction projects from 2023-2027, looks at the (1) evaluation of existing CSO projects and new treatment technologies, (2) evaluation of real-time collection system controls, (3) more accurate and complete data on CSO discharge frequency and volume, (4) benefits of less flow to the collection system from green storm water infrastructure (GSI), (5) benefits of less flow to the collection system due to the City's drainage charge program and new storm water ordinance, (6) benefits of less flow to the collection system as the City continues its sewer rehabilitation program, and (7) any other pertinent information. The permittees shall use the above measures, as appropriate, to further reduce untreated CSO discharges on an ongoing basis from the collection system before starting CSO projects from 2023 - 2037.

On or before April 1st (annually starting in 2020), the permittees shall prepare a joint Progress Report that summarizes; 1) significant real time controls that occurred during the preceding calendar year, 2) GSI implementation work during the preceding year that has been undertaken and completed, including a work plan for GSI implementation projects for the next year, documentation of the annual expenditure for the preceding year, and documentation of a cumulative total-spent-to-date on the GSI program, 3) benefits from the new storm water ordinance and green credit program, and 4) benefits from the City sewer rehabilitation program. The report shall summarize the total benefits from all programs by including; a) an updated estimate of the annual volume of wet weather flow that has been removed from the combined sewer system, b) the resulting frequency, volume and duration of CSO discharges (based on actual monitoring), and c) the predicted change modeled continuously and at design events to frequency, volume and duration of CSO discharges based on the calibrated hydraulic model developed in the Master Plan effort. The report shall reference the CSO discharge report submitted under Part I.A.15.d.(13) of this permit and include the pertinent data as a reference. As part of this reporting process, it shall be documented that an average of \$3 million dollars per fiscal year was spent for 2018

and 2019, and \$2 million dollars per year for 2020, 2021, and 2022 for the GSI program (these expenditures are an enforceable requirement of this permit).

A more complete description of the adaptive management approach includes:

a) Real-time Control

The GLWA is in the process of determining if real-time control can be used to help further minimize or even eliminate some untreated CSO discharges. One real-time control discussion currently taking place is the Interim Wet Weather Operations Plan (IWOP). The operational changes agreed to between the permittees and the Department in the IWOP will be reported in the Operational Plan Annual Update (Part 1.A.15 d.). The IWOP is evaluating if critical system regulators, gates, pumps, etc., can be adjusted to allow for more treated CSO, and less untreated CSO from the remaining CSO outfalls. Approved adjustments will be at least acceptable until completion of all non-core CSO correction projects and shall be included in Operational Plan Annual Updates. The evaluation shall include all necessary supporting documentation, including hydraulic model runs if appropriate.

b) Green Storm Water Infrastructure (GSI)

For the west side of the City, there is a GSI program in the tributary area to Rouge River Outfalls 059-069, 072-075, 077, and 079. DWSD has developed and is implementing a Department approved GSI Plan for this area consistent with the "Evaluation of CSO Control Alternatives" report dated December 15, 2009. The GSI Plan describes a process for locating, designing, constructing, operating, and evaluating GSI in these sewersheds. GSI implementation shall be planned to capture, reduce, or otherwise control wet weather flows that would otherwise flow into the sewer system and contribute to CSOs, at the permittees' direction. The Plan includes the following elements:

- (1) Provisions for disconnection of residential downspouts and disconnection of commercial and industrial downspouts where feasible (see Part I.A.15.c.).
- (2) Provisions for demolition and removal of vacant structures and replacement with pervious land cover. Where demolition is planned and implemented at sites that will be re-purposed for GSI, the demolition specifications shall ensure that basements and other impervious surfaces at the sites are removed, that the site is raked to remove large rocks and construction debris, and that engineered soils consisting of an appropriate mix of topsoil, compost, and sand is applied following the demolition to support plant growth and promote infiltration.
- (3) Provisions for installation of bioswales along roadways and parking lots to intercept runoff and reduce storm water inputs to the combined sewer system from impervious surfaces.
- (4) Provisions for installation of GSI and/or BMPs at commercial and residential properties to capture and retard storm water runoff.
- (5) Provisions for tree planting for uptake and evapotranspiration along roadways and open spaces.
- (6) Provisions for other GSI implementation projects as determined to be appropriate.
- (8) Processes for public outreach and public participation in selecting sites and implementing GSI practices.
- (9) Procedures/methods for tracking GSI implementation and measuring effects.
- (10) Provisions for ensuring appropriate maintenance of sites where GSI has been implemented, including roles and schedules for maintenance.
- (11) Provisions for ensuring storm water management (runoff reduction) benefits associated with GSI implementation continue over time, even as redevelopment may occur in the sewersheds.

The permittees shall continue to implement GSI in these sewersheds. The investment in GSI in these sewersheds shall be an average of 3 million dollars per fiscal year for the ten-year period ending 2019

(for a total of \$30 million), and an average of 2 million dollars per year for the following 10 years (for a total of \$20 million). GSI implementation will be in accordance with the GSI Plan.

For the near-east side of the City, there has been another GSI program in the tributary area to Detroit River Outfalls 005 - 009, 011, and 012. Because of the potential for some larger-scale green projects due to a relatively large amount of vacant land in the area, it may be possible to eliminate or reduce the size of some previously envisioned CSO treatment facilities for this area using the combination of GSI implementation along with possible sewer separation, and other engineering solutions. With GSI implementation now spreading across the city, it is acceptable for the city to use one-third (1/3) of the total GSI expenditures on projects upstream of untreated CSOs other than Rouge River Outfalls 059-069, 072-075, 077, and 079.

c) Storm Water Control

1) On or before April 1, 2018, (submitted) the permittees shall submit to the Department for review and approval a storm water control requirement for areas of new development and/or redevelopment. This storm water control requirement is primarily a focus within the Rouge Sewer District and Central Sewer District, as it is these two Districts that have untreated CSOs. Therefore, the permittees shall propose a level of storm water control for new development and redevelopment in these two sewer districts, and for the circumstances stated above, that is designed to help further reduce the volume and frequency of untreated CSO discharges, and a procedure and schedule for implementing this control requirement.

2) Storm water runoff from new development and redevelopment that will be conveyed through storm sewers to DWSD's combined sewers will require control to help further reduce volume and frequency of untreated CSO discharges. These are projects that will require construction plan review by the permittees, and a Part 41 construction permit issued by the Department. Please note that in most cases, new combined sewers will no longer be permitted under Part 41 (except for combined sewer relocation projects). Note that this is not a requirement for storm sewers subject to Permit No. MIS040000 issued to the City of Detroit, as the storm sewers under MIS040000 discharge directly to surface waters and are not owned by the DWSD.

d) City Sewer Rehabilitation

DWSD is currently working on a more robust annual program to remove infiltration/inflow (I/I) from its combined collection system. It is the Department's understanding that this program has a budget of about \$20 million per year.

g. Combined Sewer Overflow Control Program Schedule

1) West-side Model; Rouge River Outfalls 059-069, Outfalls 072-075, Outfall 077, and Outfall 079. For untreated combined sewer overflows from Outfalls 059-069, Outfalls 072-075, Outfall 077, and Outfall 079, the permittees shall determine the accurate frequency and volume of untreated CSO discharges and amend the "Supplemental Report on Alternative CSO Controls for the Upper Rouge River," dated April 30, 2010 according to the following schedule:

- a) The work plan has been approved by the Department that (1) sets forth the monitoring of the 17 CSOs that will be accomplished to accurately determine the frequency and volume of these untreated CSO discharges, (2) uses this monitoring along with the current Ovation monitoring as appropriate in a calibrated and verified model to accurately detail the volume and frequency of the 17 CSOs during a representative and typical 10-year period of rainfall record, and (3) to determine the peak hour flow at the 10 yr – 1 hr event of each of the 17 CSOs. The permittees shall continue to implement the approved work plan.
- b) On or before April 15, 2019, (submitted) the permittees shall submit a report to the Department for review and approval that summarizes the determination and provides the volume and frequency of these 17 CSOs over a representative and typical 10-year period of rainfall record and provides the peak hour flow at the 10 yr – 1 hr event for each of these 17 CSOs;

- c) On or before November 15, 2022, the permittees shall submit an amendment for Department review and approval to the "Supplemental Report on Alternative CSO Controls for the Upper Rouge River" (dated April 30, 2010) that describes any changes to the recommended long-term CSO control projects for the 17 CSOs. This plan may propose an alternative to the use of 10 minutes of detention at the 10 year – 1 hour event, at the permittees' discretion;
- 2) Near eastside; Detroit River Outfalls 005-009, 011, and 012. The permittees shall develop a revised CSO Control Plan for this tributary area in accordance with the following schedule:

On or before November 15, 2022, the permittees shall submit to the Department for review and approval an update to their Long-term CSO Control program (Detroit update 2008) for providing elimination or adequate treatment of CSO Outfalls 005-009, Outfall 011, and Outfall 012 to meet water quality standards at times of discharge. This plan shall consider the GI recommendations and potential for storm water reduction from the completed 205(j) report for this area. This plan may propose an alternative control requirement for the Long-term CSO control program.
- 3) The permittees may choose to offer an entire updated Long-term CSO Control program for all Detroit River CSOs. This updated plan can include a totally revised Detroit update (2008) for all remaining CSOs. Note that CSOs can be prohibited, eliminated, or adequately treated to meet water quality standards at times of discharge. If the permittees decide to pursue this approach, then the revised plan is due on or before November 15, 2022, for Department review and approval.

Following implementation of any phase of any of the approved Control Programs contained in Part I.A.15.f. and g. of this permit, the Control Program(s) may be reevaluated by the permittees or the Department. Future permits may include requirements to conduct water quality evaluations designed to verify that the overall CSO control program is providing adequate treatment to meet water quality standards. This permit may be modified in accordance with applicable laws and rules, to incorporate revisions necessary to conform to pertinent rules or laws, or as necessary to address prevailing situations, such as technical or financial constraints.

h. Notification and Testing Requirements

The federal rule promulgated by the United States Environmental Protection Agency in 40 CFR Part 122 establishing the public notification requirements for CSO discharges to the Great Lakes basin took effect February 7, 2018.

On or before August 7, 2018, (submitted) the permittees shall submit to the Department for approval, a public notification plan in accordance with 40 CFR 122.38(c). Additionally, on or before April 4, 2022, with the application for reissuance, the permittees shall submit to the Department for approval, an updated public notification plan.

Beginning November 7, 2018, all permittees authorized to discharge untreated or treated CSO to the Great Lakes Basin must provide public notification of CSO discharges in accordance with 40 CFR 122.38(a) and the approved public notification plan. The requirements include but are not limited to the following: notification of the local public health department, other potentially affected public entities and the public; and signage, where feasible at discharge points and other potentially impacted public access areas. In addition, in accordance with Section 324.3112a of the NREPA, the permittees shall provide notification to a newspaper of general circulation in the county in which the discharge occurred or is occurring. To the extent that a conflict may arise between Part I.A.15.h. and Part I.A.16., the Department approved Public Notification Plan shall govern.

16. Untreated or Partially Treated Sewage Discharge Reporting and Testing Requirements

In accordance with Section 324.3112a of the NREPA, if untreated or partially treated sewage is directly or indirectly discharged from a sewer system onto land or into the waters of the state, the entity responsible for the sewer system shall immediately, but not more than 24 hours after the discharge begins, notify, by telephone, the Department, local health departments, a daily newspaper of general circulation in the county in which the permittees are located, and a daily newspaper of general circulation in the county or counties in which the municipalities whose waters may be affected by the discharge are located that the discharge is occurring.

The permittees shall also annually contact municipalities, including the superintendent of a public drinking water supply with potentially affected intakes, whose waters may be affected by the permittees' discharge of untreated or partially treated sewage, and, if those municipalities wish to be notified in the same manner as specified above, the permittees shall provide such notification. Such notification shall also include a daily newspaper in the county of the affected municipality.

At the conclusion of the discharge, written notification shall be submitted in accordance with and on the "Report of Discharge Form" available via the internet at: <http://www.deq.state.mi.us/csosso/>, or, alternatively for combined sewer overflow discharges, in accordance with notification procedures approved by the Department.

In addition, in accordance with Section 324.3112a of the NREPA, each time a discharge of untreated or partially treated sewage occurs, the permittees shall test the affected waters for *Escherichia coli* to assess the risk to the public health as a result of the discharge and shall provide the test results to the affected local county health departments and to the Department. The testing shall be done at locations specified by each affected local county health department but shall not exceed ten (10) tests for each separate discharge event. The affected local county health department may waive this testing requirement, if it determines that such testing is not needed to assess the risk to the public health as a result of the discharge event. The results of this testing shall be submitted with the written notification required above, or, if the results are not yet available, submitted as soon as they become available. This testing is not required, if the testing has been waived by the local health department, or if the discharge(s) did not affect surface waters.

Permittees accepting sanitary or municipal sewage from other sewage collection systems are encouraged to notify the owners of those systems of the above reporting and testing requirements.

17. Pollutant Minimization and Source Evaluation Program for Perfluorooctane Sulfonate (PFOS) and/or Perfluorooctanoic Acid (PFOA)

The goal of the Pollutant Minimization and Source Evaluation Program is to identify and address sources of perfluorooctane sulfonate (PFOS) and/or perfluorooctanoic acid (PFOA) and to reduce and maintain the effluent concentrations of PFOS and/or PFOA at or below the water quality standards (WQS) and/or the Water Quality-Based Effluent limit (WQBEL). The WQS is 11 ng/L for PFOS and the WQBEL for PFOA is 8.04 ug/l.

On or before October 1, 2019, the permittee shall submit an approvable Pollutant Minimization and Source Evaluation Program for PFOS and/or PFOA to proceed toward the goal. The Pollutant Minimization and Source Evaluation Program shall continue work under the IPP Interim Initiative and shall include the following at a minimum:

- a. Identification of and strategies to identify any additional potential and probable PFOS and/or PFOA sources
- b. Monitoring plan for the permitted facility's influent and effluent and effluent from potential sources
- c. Implemented measures thus far to eliminate, reduce, and/or control sources, and an assessment of the degree of success and the strategies used to measure success
- d. Proposed measures and implementation schedules for elimination, control, and/or reduction of the identified sources (prioritizing highest loadings and concentrations), and the strategies that will be used to measure success

The Pollutant Minimization and Source Evaluation Program shall be implemented upon approval by the Department.

On or before May 1 of each year following Pollutant Minimization and Source Evaluation Program implementation, the permittee shall submit to the Department a status report for the previous calendar year. Upon written notification by the Department, the permittee may be required to submit more frequent status reports. Status reports at a minimum shall include:

- a. Complete listing of PFOS and/or PFOA sources
- b. Summary of influent and effluent monitoring data
- c. Summary of monitoring data from known or potential sources
- d. History and compliance status for sources
- e. Implemented measures to eliminate, reduce, or control sources, (prioritizing highest loadings and concentrations), and an assessment of the degree of success and the strategies used to measure success
- f. Proposed measures and schedules for elimination, control, or reduction of any newly identified PFOS and/or PFOA sources (prioritizing highest loadings and concentrations), and the strategies that will be used to measure success
- g. Barriers to implementation and revisions to the implementation schedule
- h. Laboratory reports, if not previously supplied

Any information generated as a result of the Pollutant Minimization and Source Evaluation Program set forth in this permit may be used to support a request to modify the Pollutant Minimization and Source Evaluation Program or to demonstrate that the requirement has been completed satisfactorily.

A request for modification of the approved Pollutant Minimization and Source Evaluation Program shall be submitted in writing to the Department along with supporting documentation for review and approval. The Department may approve modifications to the approved Pollutant Minimization and Source Evaluation Program, including a reduction in the frequency of the influent and known or potential source monitoring requirements. Approval of a Pollutant Minimization and Source Evaluation Program modification does not require a permit modification.

This permit may be modified in accordance with applicable laws and rules to include additional PFOS and/or PFOA conditions and/or limitations as necessary.

18. Collection System Contingency Plan

An emergency condition at the WRRF might occur that requires reduced (or even no) influent flows to the WRRF. Under Rule 299.2959 of Part 41, the permittee is required to minimize discharge of excessive pollutants. On or before July 1, 2020, the permittee shall submit to the Department for review and approval, a report that documents how the collection system and WRRF would be operated if an emergency condition required reduced influent flow (or no flow) to the WRRF to minimize discharge of excessive pollutants per Rule 299.2959 of Part 41 of PA 451. This could involve in-system storage of flows, use of Retention Treatment Basins for storage and potentially treated discharge, rerouting of flow, use of portions of the WRRF as appropriate, etc. The report shall evaluate operation of the collection system and WRRF, considering at least two hypothetical conditions with no influent flow to the WRRF; a duration of six (6) hours of no influent flow, and a duration of 24 hours of no influent flow.

19. Facility Contact

The "Facility Contact" was specified in the application. The permittees may replace the facility contact at any time, and shall notify the Department in writing within 10 days after replacement (including the name, address and telephone number of the new facility contact).

- a. The facility contact shall be (or a duly authorized representative of this person):
 - for a corporation, a principal executive officer of at least the level of vice president; or a designated representative if the representative is responsible for the overall operation of the facility from which the discharge originates, as described in the permit application or other NPDES form,
 - for a partnership, a general partner,
 - for a sole proprietorship, the proprietor, or
 - for a municipal, state, or other public facility, either a principal executive officer, the mayor, village president, city or village manager or other duly authorized employee.
- b. A person is a duly authorized representative only if:
 - the authorization is made in writing to the Department by a person described in paragraph a. of this section; and
 - the authorization specifies either an individual or a position having responsibility for the overall operation of the regulated facility or activity such as the position of plant manager, operator of a well or a well field, superintendent, position of equivalent responsibility, or an individual or position having overall responsibility for environmental matters for the facility (a duly authorized representative may thus be either a named individual or any individual occupying a named position).

Nothing in this section obviates the permittees from properly submitting reports and forms as required by law.

20. Monthly Operating Reports

Part 41 of Act 451 of 1994 as amended, specifically Section 324.4106 and associated R 299.2953, requires that the permittees file with the Department, on forms prescribed by the Department, operating reports showing the effectiveness of the treatment facility operation and the quantity and quality of liquid wastes discharged into waters of the state.

Within thirty (30) days of the effective date of this permit, the permittees shall submit to the Department a revised treatment facility monitoring program to address monitoring requirement changes reflected in this permit, or submit justification explaining why monitoring requirement changes reflected in this permit do not necessitate revisions to the treatment facility monitoring program. The permittees shall implement the revised treatment facility monitoring program upon approval from the Department. Applicable forms and guidance are available on the Department's web site at http://www.michigan.gov/deq/0,1607,7-135-3313_44117---,00.html. The permittees may use alternate forms if they are consistent with the approved treatment facility monitoring program. Unless the Department provides written notification to the permittees that monthly submittal of operating reports is required, operating reports that result from implementation of the approved treatment facility monitoring program shall be maintained on site for a minimum of three (3) years and shall be made available to the Department for review upon request.

21. Discharge Monitoring Report – Quality Assurance Study Program

The permittees shall participate in the Discharge Monitoring Report – Quality Assurance (DMR-QA) Study Program. The purpose of the DMR-QA Study Program is to annually evaluate the proficiency of all in-house and/or contract laboratory(ies) that perform, on behalf of the facility authorized to discharge under this permit, the analytical testing required under this permit. In accordance with Section 308 of the Clean Water Act (33 U.S.C. § 1318); and R 323.2138 and R 323.2154 of Part 21, Wastewater Discharge Permits, promulgated under Part 31 of the NREPA, participation in the DMR-QA Study Program is required for all major facilities, and for minor facilities selected for participation by the Department.

Annually and in accordance with DMR-QA Study Program requirements and submittal due dates, the permittees shall submit to the Michigan DMR-QA Study Program state coordinator all documentation required by the DMR-QA Study. DMR-QA Study Program participation is required only for the analytes required under this permit and only when those analytes are also identified in the DMR-QA Study.

If the permitted facility's status as a major facility should change, participation in the DMR-QA Study Program may be reevaluated. Questions concerning participation in the DMR-QA Study Program should be directed to the Michigan DMR-QA Study Program state coordinator.

All forms and instructions required for participation in the DMR-QA Study Program, including submittal due dates and state coordinator contact information, can be found at <http://www.epa.gov/compliance/discharge-monitoring-report-quality-assurance-study-program>.

Section B. Storm Water Pollution Prevention

This section is not required.

PART I**Section C. Industrial Waste Pretreatment Program****1. Federal Industrial Pretreatment Program**

- a. The permittees shall implement the Federal Industrial Pretreatment Program approved on June 26, 1997, and any subsequent modifications approved up to the issuance of this permit. Approval of substantial program modifications after the issuance of this permit shall be incorporated into this permit by minor modification in accordance with 40 CFR 122.63.
- b. The permittees shall comply with R 323.2301 through R 323.2317 of the Michigan Administrative Code (Part 23 Rules), the General Pretreatment Regulations for Existing and New Sources of Pollution (40 CFR Part 403), and the approved Federal Industrial Pretreatment Program.
- c. The permittees shall have the legal authority and necessary interjurisdictional agreements that provide the basis for the implementation and enforcement of the approved Federal Industrial Pretreatment Program throughout the service area. The legal authority and necessary interjurisdictional agreements shall include, at a minimum, the authority to carry out the activities specified in R 323.2306(a).
- d. The permittees shall develop procedures which describe, in sufficient detail, program commitments which enable implementation of the approved Federal Industrial Pretreatment Program, 40 CFR Part 403, and the Part 23 Rules in accordance with R 323.2306(c).
- e. The permittees shall establish an interjurisdictional agreement (or comparable document) with all tributary governmental jurisdictions. Each interjurisdictional agreement shall contain, at a minimum, the following:
 - 1) identification of the agency responsible for the implementation and enforcement of the approved Federal Industrial Pretreatment Program within the tributary governmental jurisdiction's boundaries; and
 - 2) the provision of the legal authority which provides the basis for the implementation and enforcement of the approved Federal Industrial Pretreatment Program within the tributary governmental jurisdiction's boundaries.
- f. The permittees shall prohibit discharges that:
 - 1) cause, in whole or in part, the permittees, failure to comply with any condition of this permit or the NREPA;
 - 2) restrict, in whole or in part, the permittee's management of biosolids;
 - 3) cause, in whole or in part, operational problems at the treatment facility or in its collection system;
 - 4) violate any of the general or specific prohibitions identified in R 323.2303(1) and (2);
 - 5) violate categorical standards identified in R 323.2311; and
 - 6) violate local limits established in accordance with R 323.2303(4).
- g. The permittees shall maintain a list of its nondomestic users that meet the criteria of a significant industrial user as identified in R 323.2302(cc).
- h. The permittees shall develop an enforcement response plan which describes, in sufficient detail, program commitments which will enable the enforcement of the approved Federal Industrial Pretreatment Program, 40 CFR Part 403, and the Part 23 Rules in accordance with R 323.2306(g).

- i. The Department may require modifications to the approved Federal Industrial Pretreatment Program which are necessary to ensure compliance with 40 CFR Part 403 and the Part 23 Rules in accordance with R 323.2309.
- j. The permittees shall not implement changes or modifications to the approved Federal Industrial Pretreatment Program without notification to the Department. Any substantial modification shall be subject to Department public noticing and approval in accordance with R 323.2309.
- k. The permittees shall maintain an adequate revenue structure and staffing level for effective implementation of the approved Federal Industrial Pretreatment Program.
- l. The permittees shall develop and maintain, for a minimum of three (3) years, all records and information necessary to determine nondomestic user compliance with 40 CFR Part 403, Part 23 Rules and the approved Federal Industrial Pretreatment Program. This period of retention shall be extended during the course of any unresolved enforcement action or litigation regarding a nondomestic user or when requested by the Department or the United States Environmental Protection Agency. All of the aforementioned records and information shall be made available upon request for inspection and copying by the Department and the United States Environmental Protection Agency.
- m. The permittees shall evaluate the approved Federal Industrial Pretreatment Program for compliance with the 40 CFR Part 403, Part 23 Rules and the prohibitions stated in item f. (above). Based upon this evaluation, the permittees shall propose to the Department all necessary changes or modifications to the approved Federal Industrial Pretreatment Program no later than the next Industrial Pretreatment Program Annual Report due date (see item o. below).
- n. The permittees shall develop and enforce local limits to implement the prohibitions listed in item f above. Local limits shall be based upon data representative of actual conditions demonstrated in a maximum allowable headworks loading analysis. An evaluation of whether the existing local limits need to be revised shall be submitted to the Department by June 1, 2021. The submittal shall provide a technical evaluation of the basis upon which this determination was made which includes information regarding the maximum allowable headworks loading, collection system protection criteria, and worker health and safety, based upon data collected since the last local limits review.

The following pollutants shall be evaluated:

- 1) Arsenic, Cadmium, Chromium, Copper, Cyanide, Lead, Mercury, Nickel, Silver, and Zinc;
 - 2) Pollutants that are subject to limits or monitoring in this permit;
 - 3) Pollutants that have an existing local limit; and,
 - 4) Other pollutants of concern which would reasonably be expected to be discharged or transported by truck or rail or otherwise introduced into the POTW.
- o. On or before April 1 of each year, the permittees shall submit to the Department, as required by R 323.2310(8), an Industrial Pretreatment Program Annual Report on the status of program implementation and enforcement activities. The reporting period shall begin on January 1 and end on December 31. At a minimum, the Industrial Pretreatment Program Annual Report shall include:
- 1) the Pretreatment Program Report data identified in Appendix A to 40 CFR part 127 – NPDES Electronic Reporting;
 - 2) a summary of changes to the approved IPP that have not been previously reported to the Department;

- 3) a summary of results of all the sampling and analyses performed of the WRRF's influent, effluent, and biosolids conducted in accordance with approved methods during the reporting period. The summary shall include the monthly average, daily maximum, quantification level, and number of samples analyzed for each pollutant. At a minimum, the results of analyses for all locally limited parameters for at least one monitoring event that tests influent, effluent and biosolids during the reporting period shall be submitted with each report, unless otherwise required by the Department. Sample collection shall be at intervals sufficient to provide pollutant removal rates, unless the pollutant is not measurable; and;
 - 4) any other relevant information requested by the Department.
- p. The permittee is required under this permit and R 323.2303(4) of the Michigan Administrative Code to review and update their local limits when:
- 1) New pollutants are introduced.
 - 2) New pollutants that were previously unevaluated are identified
 - 3) New water quality or biosolids standards are established or additional information becomes available about the nature of pollutants, such as removal rates and accumulation in biosolids. Substantial increases of pollutants are proposed as required in the notification of new or increased uses in accordance with the provisions of 40 CFR 122.42.

2. Schedule for Notification to Contributing Jurisdictions

On or before May 1st and November 1st of each year, the permittees shall submit to the Department a report demonstrating the efforts and progress toward achieving the requirement of having all contributing jurisdictions adopt a legal authority that is equivalent to or more restrictive than the permittees', including the revised local limits to be incorporated by the permittees as result of the requirements of Part I.C.2. of this permit. This legal authority includes the provisions of Ordinance 08-05 (Detroit City Code Chapter 56, Article III. Division 3) and subsequent revisions to the local limits. These progress reports shall be submitted every six months until the requirement is achieved. The biannual progress reports shall contain:

- a. a listing of all contributing jurisdictions,
- b. the status of each contributing jurisdiction's adoption of adequate legal authority, and
- c. for contributing jurisdictions who have not yet adopted adequate legal authority, a description of the steps/actions the permittees have taken to assure progress toward the contributing jurisdiction's adoption of adequate legal authority.

The permittees shall, to the best of its ability, work with those contributing jurisdictions who did not adopt adequate legal authority by January 1, 2008, to obtain such legal authority.

PART I**Section D. Residuals Management Program****1. Residuals Management Program for Land Application of Biosolids**

The permittees are authorized to land-apply bulk biosolids or prepare bulk biosolids for land application in accordance with the permittees' approved Residuals Management Program (RMP) approved on April 22, 2008, and approved modifications thereto, in accordance with the requirements established in R 323.2401 through R 323.2418 of the Michigan Administrative Code (Part 24 Rules). The approved RMP, and any approved modifications thereto, are enforceable requirements of this permit. Incineration, landfilling and other residual disposal activities shall be conducted in accordance with Part II.D.7. of this permit. The Part 24 Rules can be obtained via the internet (<http://www.michigan.gov/deq/> and on the left side of the screen click on Water, Biosolids & Industrial Pretreatment, Biosolids then click on Biosolids Laws and Rules Information which is under the Laws & Rules banner in the center of the screen).

a. Annual Report

On or before October 30 of each year, the permittees shall submit an annual report to the Department for the previous fiscal year of October 1 through September 30. The report shall be submitted electronically via the Department's MiWaters system at <https://miwaters.deq.state.mi.us>. At a minimum, the report shall contain:

- 1) a certification that current residuals management practices are in accordance with the approved RMP, or a proposal for modification to the approved RMP; and
- 2) a completed Biosolids Annual Report Form, available at <https://miwaters.deq.state.mi.us>.

b. Modifications to the Approved RMP

Prior to implementation of modifications to the RMP, the permittees shall submit proposed modifications to the Department for approval. The approved modification shall become effective upon the date of approval. Upon written notification, the Department may impose additional requirements and/or limitations to the approved RMP as necessary to protect public health and the environment from any adverse effect of a pollutant in the biosolids.

c. Record Keeping

Records required by the Part 24 Rules shall be kept for a minimum of five years. However, the records documenting cumulative loading for sites subject to cumulative pollutant loading rates shall be kept as long as the site receives biosolids.

d. Contact Information

RMP related submittals to the Department shall be to the Southeast Michigan District Supervisor of the Water Resources Division. The Southeast Michigan District Office is located at 27700 Donald Court, Warren Michigan, 48092-2793, Telephone: 586-753-3750, Fax: 586-753-3751.

PART II

Part II may include terms and /or conditions not applicable to discharges covered under this permit.

Section A. Definitions

Acute toxic unit (TU_A) means $100/LC_{50}$ where the LC_{50} is determined from a whole effluent toxicity (WET) test which produces a result that is statistically or graphically estimated to be lethal to 50% of the test organisms.

Annual monitoring frequency refers to a calendar year beginning on January 1 and ending on December 31. When required by this permit, an analytical result, reading, value or observation shall be reported for that period if a discharge occurs during that period.

Authorized public agency means a state, local, or county agency that is designated pursuant to the provisions of section 9110 of Part 91 of the NREPA to implement soil erosion and sedimentation control requirements with regard to construction activities undertaken by that agency.

Best management practices (BMPs) means structural devices or nonstructural practices that are designed to prevent pollutants from entering into storm water, to direct the flow of storm water, or to treat polluted storm water.

Bioaccumulative chemical of concern (BCC) means a chemical which, upon entering the surface waters, by itself or as its toxic transformation product, accumulates in aquatic organisms by a human health bioaccumulation factor of more than 1000 after considering metabolism and other physiochemical properties that might enhance or inhibit bioaccumulation. The human health bioaccumulation factor shall be derived according to R 323.1057(5). Chemicals with half-lives of less than 8 weeks in the water column, sediment, and biota are not BCCs. The minimum bioaccumulation concentration factor (BAF) information needed to define an organic chemical as a BCC is either a field-measured BAF or a BAF derived using the biota-sediment accumulation factor (BSAF) methodology. The minimum BAF information needed to define an inorganic chemical as a BCC, including an organometal, is either a field-measured BAF or a laboratory-measured bioconcentration factor (BCF). The BCCs to which these rules apply are identified in Table 5 of R 323.1057 of the Water Quality Standards.

Biosolids are the solid, semisolid, or liquid residues generated during the treatment of sanitary sewage or domestic sewage in a treatment works. This includes, but is not limited to, scum or solids removed in primary, secondary, or advanced wastewater treatment processes and a derivative of the removed scum or solids.

Bulk biosolids means biosolids that are not sold or given away in a bag or other container for application to a lawn or home garden.

Certificate of Coverage (COC) is a document, issued by the Department, which authorizes a discharge under a general permit.

Chronic toxic unit (TU_C) means $100/MATC$ or $100/IC_{25}$, where the maximum acceptable toxicant concentration (MATC) and IC_{25} are expressed as a percent effluent in the test medium.

Class B biosolids refers to material that has met the Class B pathogen reduction requirements or equivalent treatment by a Process to Significantly Reduce Pathogens (PSRP) in accordance with the Part 24 Rules. Processes include aerobic digestion, composting, anaerobic digestion, lime stabilization and air drying.

Combined sewer system is a sewer system in which storm water runoff is combined with sanitary wastes.

Daily concentration is the sum of the concentrations of the individual samples of a parameter divided by the number of samples taken during any calendar day. If the parameter concentration in any sample is less than the quantification limit, regard that value as zero when calculating the daily concentration. The daily concentration will be used to determine compliance with any maximum and minimum daily concentration limitations (except for pH and dissolved oxygen). When required by the permit, report the maximum calculated daily concentration for the month in the "MAXIMUM" column under "QUALITY OR CONCENTRATION" on the Discharge Monitoring Reports (DMRs).

For pH, report the maximum value of any *individual* sample taken during the month in the "MAXIMUM" column under "QUALITY OR CONCENTRATION" on the DMRs and the minimum value of any *individual* sample taken during the month in the "MINIMUM" column under "QUALITY OR CONCENTRATION" on the DMRs. For dissolved oxygen, report the minimum concentration of any *individual* sample in the "MINIMUM" column under "QUALITY OR CONCENTRATION" on the DMRs.

Daily loading is the total discharge by weight of a parameter discharged during any calendar day. This value is calculated by multiplying the daily concentration by the total daily flow and by the appropriate conversion factor. The daily loading will be used to determine compliance with any maximum daily loading limitations. When required by the permit, report the maximum calculated daily loading for the month in the "MAXIMUM" column under "QUANTITY OR LOADING" on the DMRs.

Daily monitoring frequency refers to a 24-hour day. When required by this permit, an analytical result, reading, value or observation shall be reported for that period if a discharge occurs during that period.

Department means the Michigan Department of Environment, Great Lakes, and Energy.

Detection level means the lowest concentration or amount of the target analyte that can be determined to be different from zero by a single measurement at a stated level of probability.

Discharge means the addition of any waste, waste effluent, wastewater, pollutant, or any combination thereof to any surface water of the state.

EC₅₀ means a statistically or graphically estimated concentration that is expected to cause 1 or more specified effects in 50% of a group of organisms under specified conditions.

Fecal coliform bacteria monthly

FOR WWSLs THAT COLLECT AND STORE WASTEWATER AND ARE AUTHORIZED TO DISCHARGE ONLY IN THE SPRING AND/OR FALL ON AN INTERMITTENT BASIS – Fecal coliform bacteria monthly is the geometric mean of all daily concentrations determined during a discharge event. Days on which no daily concentration is determined shall not be used to determine the calculated monthly value. The calculated monthly value will be used to determine compliance with the maximum monthly fecal coliform bacteria limitations. When required by the permit, report the calculated monthly value in the "AVERAGE" column under "QUALITY OR CONCENTRATION" on the DMR. If the period in which the discharge event occurred was partially in each of two months, the calculated monthly value shall be reported on the DMR of the month in which the last day of discharge occurred.

FOR ALL OTHER DISCHARGES – Fecal coliform bacteria monthly is the geometric mean of all daily concentrations determined during a reporting month. Days on which no daily concentration is determined shall not be used to determine the calculated monthly value. The calculated monthly value will be used to determine compliance with the maximum monthly fecal coliform bacteria limitations. When required by the permit, report the calculated monthly value in the "AVERAGE" column under "QUALITY OR CONCENTRATION" on the DMR.

Fecal coliform bacteria 7-day

FOR WWSLs THAT COLLECT AND STORE WASTEWATER AND ARE AUTHORIZED TO DISCHARGE ONLY IN THE SPRING AND/OR FALL ON AN INTERMITTENT BASIS – Fecal coliform bacteria 7-day is the geometric mean of the daily concentrations determined during any 7 consecutive days of discharge during a discharge event. If the number of daily concentrations determined during the discharge event is less than 7 days, the number of actual daily concentrations determined shall be used for the calculation. Days on which no daily concentration is determined shall not be used to determine the value. The calculated 7-day value will be used to determine compliance with the maximum 7-day fecal coliform bacteria limitations. When required by the permit, report the maximum calculated 7-day geometric mean value for the month in the “MAXIMUM” column under “QUALITY OR CONCENTRATION” on the DMRs. If the 7-day period was partially in each of two months, the value shall be reported on the DMR of the month in which the last day of discharge occurred.

FOR ALL OTHER DISCHARGES – Fecal coliform bacteria 7-day is the geometric mean of the daily concentrations determined during any 7 consecutive days in a reporting month. If the number of daily concentrations determined is less than 7, the actual number of daily concentrations determined shall be used for the calculation. Days on which no daily concentration is determined shall not be used to determine the value. The calculated 7-day value will be used to determine compliance with the maximum 7-day fecal coliform bacteria limitations. When required by the permit, report the maximum calculated 7-day geometric mean for the month in the “MAXIMUM” column under “QUALITY OR CONCENTRATION” on the DMRs. The first calculation shall be made on day 7 of the reporting month, and the last calculation shall be made on the last day of the reporting month.

Flow-proportioned sample is a composite sample with the sample volume proportional to the effluent flow.

General permit means a National Pollutant Discharge Elimination System permit issued authorizing a category of similar discharges.

Geometric mean is the average of the logarithmic values of a base 10 data set, converted back to a base 10 number.

Grab sample is a single sample taken at neither a set time nor flow.

IC₂₅ means the toxicant concentration that would cause a 25% reduction in a nonquantal biological measurement for the test population.

Illicit connection means a physical connection to a municipal separate storm sewer system that primarily conveys non-storm water discharges other than uncontaminated groundwater into the storm sewer; or a physical connection not authorized or permitted by the local authority, where a local authority requires authorization or a permit for physical connections.

Illicit discharge means any discharge to, or seepage into, a municipal separate storm sewer system that is not composed entirely of storm water or uncontaminated groundwater. Illicit discharges include non-storm water discharges through pipes or other physical connections; dumping of motor vehicle fluids, household hazardous wastes, domestic animal wastes, or litter; collection and intentional dumping of grass clippings or leaf litter; or unauthorized discharges of sewage, industrial waste, restaurant wastes, or any other non-storm water waste directly into a separate storm sewer.

Individual permit means a site-specific NPDES permit.

Inlet means a catch basin, roof drain, conduit, drain tile, retention pond riser pipe, sump pump, or other point where storm water or wastewater enters into a closed conveyance system prior to discharge off site or into waters of the state.

Interference is a discharge which, alone or in conjunction with a discharge or discharges from other sources, both: 1) inhibits or disrupts the POTW, its treatment processes or operations, or its sludge processes, use or disposal; and 2) therefore, is a cause of a violation of any requirement of the POTW's NPDES permit (including an increase in the magnitude or duration of a violation) or, of the prevention of sewage sludge use or disposal in compliance with the following statutory provisions and regulations or permits issued thereunder (or more stringent state or local regulations): Section 405 of the Clean Water Act, the Solid Waste Disposal Act (SWDA) (including Title II, more commonly referred to as the Resource Conservation and Recovery Act (RCRA), and including state regulations contained in any state sludge management plan prepared pursuant to Subtitle D of the SWDA), the Clean Air Act, the Toxic Substances Control Act, and the Marine Protection, Research and Sanctuaries Act. [This definition does not apply to sample matrix interference].

Land application means spraying or spreading biosolids or a biosolids derivative onto the land surface, injecting below the land surface, or incorporating into the soil so that the biosolids or biosolids derivative can either condition the soil or fertilize crops or vegetation grown in the soil.

LC₅₀ means a statistically or graphically estimated concentration that is expected to be lethal to 50% of a group of organisms under specified conditions.

Maximum acceptable toxicant concentration (MATC) means the concentration obtained by calculating the geometric mean of the lower and upper chronic limits from a chronic test. A lower chronic limit is the highest tested concentration that did not cause the occurrence of a specific adverse effect. An upper chronic limit is the lowest tested concentration which did cause the occurrence of a specific adverse effect and above which all tested concentrations caused such an occurrence.

Maximum extent practicable means implementation of best management practices by a public body to comply with an approved storm water management program as required by a national permit for a municipal separate storm sewer system, in a manner that is environmentally beneficial, technically feasible, and within the public body's legal authority.

MGD means million gallons per day.

Monthly concentration is the sum of the daily concentrations determined during a reporting period divided by the number of daily concentrations determined. The calculated monthly concentration will be used to determine compliance with any maximum monthly concentration limitations. Days with no discharge shall not be used to determine the value. When required by the permit, report the calculated monthly concentration in the "AVERAGE" column under "QUALITY OR CONCENTRATION" on the DMR.

For minimum percent removal requirements, the monthly influent concentration and the monthly effluent concentration shall be determined. The calculated monthly percent removal, which is equal to 100 times the quantity [1 minus the quantity (monthly effluent concentration divided by the monthly influent concentration)], shall be reported in the "MINIMUM" column under "QUALITY OR CONCENTRATION" on the DMRs.

Monthly loading is the sum of the daily loadings of a parameter divided by the number of daily loadings determined during a reporting period. The calculated monthly loading will be used to determine compliance with any maximum monthly loading limitations. Days with no discharge shall not be used to determine the value. When required by the permit, report the calculated monthly loading in the "AVERAGE" column under "QUANTITY OR LOADING" on the DMR.

Monthly monitoring frequency refers to a calendar month. When required by this permit, an analytical result, reading, value or observation shall be reported for that period if a discharge occurs during that period.

Municipal separate storm sewer means a conveyance or system of conveyances designed or used for collecting or conveying storm water which is not a combined sewer and which is not part of a publicly-owned treatment works as defined in the Code of Federal Regulations at 40 CFR 122.2.

Municipal separate storm sewer system (MS4) means all separate storm sewers that are owned or operated by the United States, a state, city, village, township, county, district, association, or other public body created by or pursuant to state law, having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under state law, such as a sewer district, flood control district, or drainage district, or similar entity, or a designated or approved management agency under Section 208 of the Federal Act that discharges to the waters of the state. This term includes systems similar to separate storm sewer systems in municipalities, such as systems at military bases, large hospital or prison complexes, and highways and other thoroughfares. The term does not include separate storm sewers in very discrete areas, such as individual buildings.

National Pretreatment Standards are the regulations promulgated by or to be promulgated by the Federal Environmental Protection Agency pursuant to Section 307(b) and (c) of the Federal Act. The standards establish nationwide limits for specific industrial categories for discharge to a POTW.

No observed adverse effect level (NOAEL) means the highest tested dose or concentration of a substance which results in no observed adverse effect in exposed test organisms where higher doses or concentrations result in an adverse effect.

Noncontact cooling water is water used for cooling which does not come into direct contact with any raw material, intermediate product, by-product, waste product or finished product.

Nondomestic user is any discharger to a POTW that discharges wastes other than or in addition to water-carried wastes from toilet, kitchen, laundry, bathing or other facilities used for household purposes.

Outfall is the location at which a point source discharge enters the surface waters of the state.

Part 91 agency means an agency that is designated by a county board of commissioners pursuant to the provisions of section 9105 of Part 91 of the NREPA; an agency that is designated by a city, village, or township in accordance with the provisions of section 9106 of Part 91 of the NREPA; or the Department for soil erosion and sedimentation activities under Part 615, Part 631, or Part 632 pursuant to the provisions of section 9115 of Part 91 of the NREPA.

Part 91 permit means a soil erosion and sedimentation control permit issued by a Part 91 agency pursuant to the provisions of Part 91 of the NREPA.

Partially treated sewage is any sewage, sewage and storm water, or sewage and wastewater, from domestic or industrial sources that is treated to a level less than that required by the permittees' National Pollutant Discharge Elimination System permit, or that is not treated to national secondary treatment standards for wastewater, including discharges to surface waters from retention treatment facilities.

Point of discharge is the location of a point source discharge where storm water is discharged directly into a separate storm sewer system.

Point source discharge means a discharge from any discernible, confined, discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, or rolling stock. Changing the surface of land or establishing grading patterns on land will result in a point source discharge where the runoff from the site is ultimately discharged to waters of the state.

Polluting material means any material, in solid or liquid form, identified as a polluting material under the Part 5 Rules (R 324.2001 through R 324.2009 of the Michigan Administrative Code).

POTW is a publicly owned treatment work.

Pretreatment is reducing the amount of pollutants, eliminating pollutants, or altering the nature of pollutant properties to a less harmful state prior to discharge into a public sewer. The reduction or alteration can be by physical, chemical, or biological processes, process changes, or by other means. Dilution is not considered pretreatment unless expressly authorized by an applicable National Pretreatment Standard for a particular industrial category.

Public (as used in the MS4 individual permit) means all persons who potentially could affect the authorized storm water discharges, including, but not limited to, residents, visitors to the area, public employees, businesses, industries, and construction contractors and developers.

Public body means the United States; the state of Michigan; a city, village, township, county, school district, public college or university, or single-purpose governmental agency; or any other body which is created by federal or state statute or law.

Qualified Personnel means an individual who meets qualifications acceptable to the Department and who is authorized by an Industrial Storm Water Certified Operator to collect the storm water sample.

Qualifying storm event means a storm event causing greater than 0.1 inch of rainfall and occurring at least 72 hours after the previous measurable storm event that also caused greater than 0.1 inch of rainfall. Upon request, the Department may approve an alternate definition meeting the condition of a qualifying storm event.

Quantification level means the measurement of the concentration of a contaminant obtained by using a specified laboratory procedure calculated at a specified concentration above the detection level. It is considered the lowest concentration at which a particular contaminant can be quantitatively measured using a specified laboratory procedure for monitoring of the contaminant.

Quarterly monitoring frequency refers to a three month period, defined as January through March, April through June, July through September, and October through December. When required by this permit, an analytical result, reading, value or observation shall be reported for that period if a discharge occurs during that period.

Regional Administrator is the Region 5 Administrator, U.S. EPA, located at R-19J, 77 W. Jackson Blvd., Chicago, Illinois 60604.

Regulated area means the permittee's urbanized area, where urbanized area is defined as a place and its adjacent densely-populated territory that together have a minimum population of 50,000 people as defined by the United States Bureau of the Census and as determined by the latest available decennial census.

Secondary containment structure means a unit, other than the primary container, in which significant materials are packaged or held, which is required by State or Federal law to prevent the escape of significant materials by gravity into sewers, drains, or otherwise directly or indirectly into any sewer system or to the surface or ground waters of this state.

Separate storm sewer system means a system of drainage, including, but not limited to, roads, catch basins, curbs, gutters, parking lots, ditches, conduits, pumping devices, or man-made channels, which is not a combined sewer where storm water mixes with sanitary wastes, and is not part of a POTW.

Significant industrial user is a nondomestic user that: 1) is subject to Categorical Pretreatment Standards under 40 CFR 403.6 and 40 CFR Chapter I, Subchapter N; or 2) discharges an average of 25,000 gallons per day or more of process wastewater to a POTW (excluding sanitary, noncontact cooling and boiler blowdown wastewater); contributes a process waste stream which makes up five (5) percent or more of the average dry weather hydraulic or organic capacity of the POTW treatment plant; or is designated as such by the permittees as defined in 40 CFR 403.12(a) on the basis that the industrial user has a reasonable potential for adversely affecting the POTW's treatment plant operation or violating any pretreatment standard or requirement (in accordance with 40 CFR 403.8(f)(6)).

Significant materials Significant Materials means any material which could degrade or impair water quality, including but not limited to: raw materials; fuels; solvents, detergents, and plastic pellets; finished materials such as metallic products; hazardous substances designated under Section 101(14) of Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) (see 40 CFR 372.65); any chemical the facility is required to report pursuant to Section 313 of Emergency Planning and Community Right-to-Know Act (EPCRA); polluting materials as identified under the Part 5 Rules (R 324.2001 through R 324.2009 of the Michigan Administrative Code); Hazardous Wastes as defined in Part 111 of the NREPA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharges.

Significant spills and significant leaks means any release of a polluting material reportable under the Part 5 Rules (R 324.2001 through R 324.2009 of the Michigan Administrative Code).

Special-use area means secondary containment structures required by state or federal law; lands on Michigan's List of Sites of Environmental Contamination pursuant to Part 201, Environmental Remediation, of the NREPA; and/or areas with other activities that may contribute pollutants to the storm water for which the Department determines monitoring is needed.

Stoichiometric means the quantity of a reagent calculated to be necessary and sufficient for a given chemical reaction.

Storm water means storm water runoff, snow melt runoff, surface runoff and drainage, and non-storm water included under the conditions of this permit.

Storm water discharge point is the location where the point source discharge of storm water is directed to surface waters of the state or to a separate storm sewer. It includes the location of all point source discharges where storm water exits the facility, including *outfalls* which discharge directly to surface waters of the state, and *points of discharge* which discharge directly into separate storm sewer systems.

SWPPP means the Storm Water Pollution Prevention Plan prepared in accordance with this permit.

Tier I value means a value for aquatic life, human health or wildlife calculated under R 323.1057 of the Water Quality Standards using a tier I toxicity database.

Tier II value means a value for aquatic life, human health or wildlife calculated under R 323.1057 of the Water Quality Standards using a tier II toxicity database.

Total maximum daily loads (TMDLs) are required by the Federal Act for waterbodies that do not meet water quality standards. TMDLs represent the maximum daily load of a pollutant that a waterbody can assimilate and meet water quality standards, and an allocation of that load among point sources, nonpoint sources, and a margin of safety.

Toxicity reduction evaluation (TRE) means a site-specific study conducted in a stepwise process designed to identify the causative agents of effluent toxicity, isolate the sources of toxicity, evaluate the effectiveness of toxicity control options, and then confirm the reduction in effluent toxicity.

Water Quality Standards means the Part 4 Water Quality Standards promulgated pursuant to Part 31 of the NREPA, being R 323.1041 through R 323.1117 of the Michigan Administrative Code.

Weekly monitoring frequency refers to a calendar week which begins on Sunday and ends on Saturday. When required by this permit, an analytical result, reading, value or observation shall be reported for that period if a discharge occurs during that period.

Wet Weather Flow is the wastewater flow (domestic, industrial, commercial and institutional) including infiltration and inflow that occurs as the result of a precipitation or snowmelt event.

Wet Weather Event, for the interim period, is defined as those days on which an average 0.10 inches or more of precipitation was recorded by six strategically located rainfall gauges (as defined in Part I.9.c.(10) of the Operational Plan) in the WRRF's service area, plus two days immediately following days of 0.10 inch to 1.00 inch days of precipitation or three days following days of 1.00 inch or more precipitation. Rainfall days are further limited to those days in which the air temperature exceeds 32° F (0° C) for at least an eight hour period. The permittee may demonstrate that certain events such as snowmelt, and other unforeseen events will be considered rainfall days.

The above definition of wet weather event is not adequate on a long term basis, or for the purposes of planning, designing, or implementing the combined sewer overflow improvements required in this permit. For purposes of planning and designing future CSO improvements, the permittee shall consider the effect of dewatering tributary storage basins on overall system recovery, both at the WRRF and CSO overflow points in the collection system.

For this permit while the Regional Operational Plan is being revised, if up to 930 MGD (including recycle) is being processed with secondary treatment at the WRRF and no primary flow is being discharged, then tributary combined or sanitary storage basins in the GLWA system may be dewatered. Such dewatering will not be considered a violation of this permit, even if contrary to the above Wet Weather Event definition. Once a revised Regional Operation Plan is developed, it shall be implemented once reviewed and approved by the Department.

Upon approval of the Department, an alternate "wet weather event" definition may be used.

WWSL is a wastewater stabilization lagoon.

WWSL discharge event is a discrete occurrence during which effluent is discharged to the surface water up to 10 days of a consecutive 14 day period.

3-portion composite sample is a sample consisting of three equal-volume grab samples collected at equal intervals over an 8-hour period.

7-day concentration

FOR WWSLs THAT COLLECT AND STORE WASTEWATER AND ARE AUTHORIZED TO DISCHARGE ONLY IN THE SPRING AND/OR FALL ON AN INTERMITTENT BASIS – The 7-day concentration is the sum of the daily concentrations determined during any 7 consecutive days of discharge during a WWSL discharge event divided by the number of daily concentrations determined. If the number of daily concentrations determined during the WWSL discharge event is less than 7 days, the number of actual daily concentrations determined shall be used for the calculation. The calculated 7-day concentration will be used to determine compliance with any maximum 7-day concentration limitations. When required by the permit, report the maximum calculated 7-day concentration for the WWSL discharge event in the "MAXIMUM" column under "QUALITY OR CONCENTRATION" on the DMR. If the WWSL discharge event was partially in each of two months, the value shall be reported on the DMR of the month in which the last day of discharge occurred.

FOR ALL OTHER DISCHARGES – The 7-day concentration is the sum of the daily concentrations determined during any 7 consecutive days in a reporting month divided by the number of daily concentrations determined. If the number of daily concentrations determined is less than 7, the actual number of daily concentrations determined shall be used for the calculation. The calculated 7-day concentration will be used to determine compliance with any maximum 7-day concentration limitations in the reporting month. When required by the permit, report the maximum calculated 7-day concentration for the month in the "MAXIMUM" column under "QUALITY OR CONCENTRATION" on the DMR. The first 7-day calculation shall be made on day 7 of the reporting month, and the last calculation shall be made on the last day of the reporting month.

7-day loading

FOR WWSLs THAT COLLECT AND STORE WASTEWATER AND ARE AUTHORIZED TO DISCHARGE ONLY IN THE SPRING AND/OR FALL ON AN INTERMITTENT BASIS – The 7-day loading is the sum of the daily loadings determined during any 7 consecutive days of discharge during a WWSL discharge event divided by the number of daily loadings determined. If the number of daily loadings determined during the WWSL discharge event is less than 7 days, the number of actual daily loadings determined shall be used for the calculation. The calculated 7-day loading will be used to determine compliance with any maximum 7-day loading limitations. When required by the permit, report the maximum calculated 7-day loading for the WWSL discharge event in the “MAXIMUM” column under “QUANTITY OR LOADING” on the DMR. If the WWSL discharge event was partially in each of two months, the value shall be reported on the DMR of the month in which the last day of discharge occurred

FOR ALL OTHER DISCHARGES – The 7-day loading is the sum of the daily loadings determined during any 7 consecutive days in a reporting month divided by the number of daily loadings determined. If the number of daily loadings determined is less than 7, the actual number of daily loadings determined shall be used for the calculation. The calculated 7-day loading will be used to determine compliance with any maximum 7-day loading limitations in the reporting month. When required by the permit, report the maximum calculated 7-day loading for the month in the “MAXIMUM” column under “QUANTITY OR LOADING” on the DMR. The first 7-day calculation shall be made on day 7 of the reporting month, and the last calculation shall be made on the last day of the reporting month.

24-hour composite sample is a flow-proportioned composite sample consisting of hourly or more frequent portions that are taken over a 24-hour period. In accordance with the Department Approved Wet Weather Operational Plan (See Part I.A.11.), alternate requirements for 24-hour composite sampling may be utilized to satisfy the monitoring requirements of this permit.

PART II

Section B. Monitoring Procedures

1. Representative Samples

Samples and measurements taken as required herein shall be representative of the volume and nature of the monitored discharge.

2. Test Procedures

Test procedures for the analysis of pollutants shall conform to regulations promulgated pursuant to Section 304(h) of the Federal Act (40 CFR Part 136 – Guidelines Establishing Test Procedures for the Analysis of Pollutants), unless specified otherwise in this permit. **Test procedures used shall be sufficiently sensitive to determine compliance with applicable effluent limitations.** Requests to use test procedures not promulgated under 40 CFR Part 136 for pollutant monitoring required by this permit shall be made in accordance with the Alternate Test Procedures regulations specified in 40 CFR 136.4. These requests shall be submitted to the Section Manager of the Permits Section, Water Resources Division, Michigan Department of Environment, Great Lakes, and Energy, P.O. Box 30458, Lansing, Michigan, 48909-7958. The permittees may use such procedures upon approval.

The permittees shall periodically calibrate and perform maintenance procedures on all analytical instrumentation at intervals to ensure accuracy of measurements. The calibration and maintenance shall be performed as part of the permittees' laboratory Quality Control/Quality Assurance program.

3. Instrumentation

The permittees shall periodically calibrate and perform maintenance procedures on all monitoring instrumentation at intervals to ensure accuracy of measurements.

4. Recording Results

For each measurement or sample taken pursuant to the requirements of this permit, the permittees shall record the following information: 1) the exact place, date, and time of measurement or sampling; 2) the person(s) who performed the measurement or sample collection; 3) the dates the analyses were performed; 4) the person(s) who performed the analyses; 5) the analytical techniques or methods used; 6) the date of and person responsible for equipment calibration; and 7) the results of all required analyses.

5. Records Retention

All records and information resulting from the monitoring activities required by this permit including all records of analyses performed and calibration and maintenance of instrumentation and recordings from continuous monitoring instrumentation shall be retained for a minimum of three (3) years, or longer if requested by the Regional Administrator or the Department.

PART II

Section C. Reporting Requirements

1. Start-up Notification

If the permittees will not discharge during the first 60 days following the effective date of this permit, the permittees shall notify the Department within 14 days following the effective date of this permit, and then 60 days prior to the commencement of the discharge.

2. Submittal Requirements for Self-Monitoring Data

Part 31 of the NREPA (specifically Section 324.3110(7)); and R 323.2155(2) of Part 21, Wastewater Discharge Permits, promulgated under Part 31 of the NREPA, allow the Department to specify the forms to be utilized for reporting the required self-monitoring data. Unless instructed on the effluent limitations page to conduct "Retained Self-Monitoring," the permittees shall submit self-monitoring data via the Department's MiWaters system.

The permittees shall utilize the information provided on the MiWaters website, located at <https://miwaters.deq.state.mi.us>, to access and submit the electronic forms. Both monthly summary and daily data shall be submitted to the Department no later than the 20th day of the month following each month of the authorized discharge period(s). The permittees may be allowed to submit the electronic forms after this date if the Department has granted an extension to the submittal date.

3. Retained Self-Monitoring Requirements

If instructed on the effluent limits page (or otherwise authorized by the Department in accordance with the provisions of this permit) to conduct retained self-monitoring, the permittees shall maintain a year-to-date log of retained self-monitoring results and, upon request, provide such log for inspection to the staff of the Department. Retained self-monitoring results are public information and shall be promptly provided to the public upon request.

The permittees shall certify, in writing, to the Department, on or before January 10th (April 1st for animal feeding operation facilities) of each year, that: 1) all retained self-monitoring requirements have been complied with and a year-to-date log has been maintained; and 2) the application on which this permit is based still accurately describes the discharge. With this annual certification, the permittees shall submit a summary of the previous year's monitoring data. The summary shall include maximum values for samples to be reported as daily maximums and/or monthly maximums and minimum values for any daily minimum samples.

Retained self-monitoring may be denied to permittees by notification in writing from the Department. In such cases, the permittees shall submit self-monitoring data in accordance with Part II.C.2., above. Such a denial may be rescinded by the Department upon written notification to the permittees. Reissuance or modification of this permit or reissuance or modification of an individual permittees' authorization to discharge shall not affect previous approval or denial for retained self-monitoring unless the Department provides notification in writing to the permittees.

4. Additional Monitoring by Permittees

If the permittees monitor any pollutant at the location(s) designated herein more frequently than required by this permit, using approved analytical methods as specified above, the results of such monitoring shall be included in the calculation and reporting of the values required in the Discharge Monitoring Report. Such increased frequency shall also be indicated.

Monitoring required pursuant to Part 41 of the NREPA or Rule 35 of the Mobile Home Park Commission Act (Act 96 of the Public Acts of 1987) for assurance of proper facility operation shall be submitted as required by the Department.

5. Compliance Dates Notification

Within 14 days of every compliance date specified in this permit, the permittees shall submit a *written* notification to the Department indicating whether or not the particular requirement was accomplished. If the requirement was not accomplished, the notification shall include an explanation of the failure to accomplish the requirement, actions taken or planned by the permittees to correct the situation, and an estimate of when the requirement will be accomplished. If a written report is required to be submitted by a specified date and the permittees accomplish this, a separate written notification is not required.

6. Noncompliance Notification

Compliance with all applicable requirements set forth in the Federal Act, Parts 31 and 41 of the NREPA, and related regulations and rules is required. All instances of noncompliance shall be reported as follows:

- a. 24-Hour Reporting
Any noncompliance which may endanger health or the environment (including maximum and/or minimum daily concentration discharge limitation exceedances) shall be reported, verbally, within 24 hours from the time the permittees becomes aware of the noncompliance. A written submission shall also be provided within five (5) days.
- b. Other Reporting
The permittees shall report, in writing, all other instances of noncompliance not described in a. above at the time monitoring reports are submitted; or, in the case of retained self-monitoring, within five (5) days from the time the permittees become aware of the noncompliance.

Written reporting shall include: 1) a description of the discharge and cause of noncompliance; and 2) the period of noncompliance, including exact dates and times, or, if not yet corrected, the anticipated time the noncompliance is expected to continue, and the steps taken to reduce, eliminate and prevent recurrence of the noncomplying discharge.

7. Spill Notification

The permittees shall immediately report any release of any polluting material which occurs to the surface waters or groundwaters of the state, unless the permittees have determined that the release is not in excess of the threshold reporting quantities specified in the Part 5 Rules (R 324.2001 through R 324.2009 of the Michigan Administrative Code), by calling the Department at the number indicated on the second page of this permit (or, if this is a general permit, on the COC); or, if the notice is provided after regular working hours, call the Department's 24-hour Pollution Emergency Alerting System telephone number, 1-800-292-4706 (calls from **out-of-state** dial 1-517-373-7660).

Within ten (10) days of the release, the permittees shall submit to the Department a full written explanation as to the cause of the release, the discovery of the release, response (clean-up and/or recovery) measures taken, and preventive measures taken or a schedule for completion of measures to be taken to prevent reoccurrence of similar releases.

8. Upset Noncompliance Notification

If a process "upset" (defined as an exceptional incident in which there is unintentional and temporary noncompliance with technology based permit effluent limitations because of factors beyond the reasonable control of the permittees) has occurred, the permittees who wishes to establish the affirmative defense of upset, shall notify the Department by telephone within 24 hours of becoming aware of such conditions; and within five (5) days, provide in writing, the following information:

- a. that an upset occurred and that the permittees can identify the specific cause(s) of the upset;
- b. that the permitted wastewater treatment facility was, at the time, being properly operated and maintained (note that an upset does not include noncompliance to the extent caused by operational error, improperly designed treatment facilities, inadequate treatment facilities, lack of preventive maintenance, or careless or improper operation); and
- c. that the permittees has specified and taken action on all responsible steps to minimize or correct any adverse impact in the environment resulting from noncompliance with this permit.

No determination made during administrative review of claims that noncompliance was caused by upset, and before an action for noncompliance, is final administrative action subject to judicial review.

In any enforcement proceedings, the permittees, seeking to establish the occurrence of an upset, has the burden of proof.

9. Bypass Prohibition and Notification

- a. Bypass Prohibition
Bypass is prohibited, and the Department may take an enforcement action, unless:
 - 1) bypass was unavoidable to prevent loss of life, personal injury, or severe property damage;
 - 2) there were no feasible alternatives to the bypass, such as the use of auxiliary treatment facilities, retention of untreated wastes, or maintenance during normal periods of equipment downtime. This condition is not satisfied if adequate backup equipment should have been installed in the exercise of reasonable engineering judgment to prevent a bypass; and
 - 3) the permittees submitted notices as required under 9.b. or 9.c. below.
- b. Notice of Anticipated Bypass
If the permittees know in advance of the need for a bypass, it shall submit prior notice to the Department, if possible at least ten (10) days before the date of the bypass, and provide information about the anticipated bypass as required by the Department. The Department may approve an anticipated bypass, after considering its adverse effects, if it will meet the three (3) conditions listed in 9.a. above.
- c. Notice of Unanticipated Bypass
The permittees shall submit notice to the Department of an unanticipated bypass by calling the Department at the number indicated on the second page of this permit (if the notice is provided after regular working hours, use the following number: 1-800-292-4706) as soon as possible, but no later than 24 hours from the time the permittees becomes aware of the circumstances.

d. Written Report of Bypass

A written submission shall be provided within five (5) working days of commencing any bypass to the Department, and at additional times as directed by the Department. The written submission shall contain a description of the bypass and its cause; the period of bypass, including exact dates and times, and if the bypass has not been corrected, the anticipated time it is expected to continue; steps taken or planned to reduce, eliminate, and prevent reoccurrence of the bypass; and other information as required by the Department.

e. Bypass Not Exceeding Limitations

The permittees may allow any bypass to occur which does not cause effluent limitations to be exceeded, but only if it also is for essential maintenance to ensure efficient operation. These bypasses are not subject to the provisions of 9.a., 9.b., 9.c., and 9.d., above. This provision does not relieve the permittees of any notification responsibilities under Part II.C.11. of this permit.

f. Definitions

1) Bypass means the intentional diversion of waste streams from any portion of a treatment facility.

2) Severe property damage means substantial physical damage to property, damage to the treatment facilities which causes them to become inoperable, or substantial and permanent loss of natural resources which can reasonably be expected to occur in the absence of a bypass. Severe property damage does not mean economic loss caused by delays in production.

10. Bioaccumulative Chemicals of Concern (BCC)

Consistent with the requirements of R 323.1098 and R 323.1215 of the Michigan Administrative Code, the permittees are prohibited from undertaking any action that would result in a lowering of water quality from an increased loading of a BCC unless an increased use request and antidegradation demonstration have been submitted and approved by the Department.

11. Notification of Changes in Discharge

The permittees shall notify the Department, in writing, as soon as possible but no later than 10 days of knowing, or having reason to believe, that any activity or change has occurred or will occur which would result in the discharge of: 1) detectable levels of chemicals on the current Michigan Critical Materials Register, priority pollutants or hazardous substances set forth in 40 CFR 122.21, Appendix D, or the Pollutants of Initial Focus in the Great Lakes Water Quality Initiative specified in 40 CFR 132.6, Table 6, which were not acknowledged in the application or listed in the application at less than detectable levels; 2) detectable levels of any other chemical not listed in the application or listed at less than detection, for which the application specifically requested information; or 3) any chemical at levels greater than five times the average level reported in the complete application (see the first page of this permit, for the date(s) the complete application was submitted). Any other monitoring results obtained as a requirement of this permit shall be reported in accordance with the compliance schedules.

12. Changes in Facility Operations

Any anticipated action or activity, including but not limited to facility expansion, production increases, or process modification, which will result in new or increased loadings of pollutants to the receiving waters must be reported to the Department by a) submission of an increased use request (application) and all information required under R 323.1098 (Antidegradation) of the Water Quality Standards or b) by notice if the following conditions are met: 1) the action or activity will not result in a change in the types of wastewater discharged or result in a greater quantity of wastewater than currently authorized by this permit; 2) the action or activity will not result in violations of the effluent limitations specified in this permit; 3) the action or activity is not prohibited by the requirements of Part II.C.10.; and 4) the action or activity will not require notification pursuant to Part II.C.11. Following such notice, the permit or, if applicable, the facility's COC may be modified according to applicable laws and rules to specify and limit any pollutant not previously limited.

13. Transfer of Ownership or Control

In the event of any change in control or ownership of facilities from which the authorized discharge emanates, the permittees shall submit to the Department 30 days prior to the actual transfer of ownership or control a written agreement between the current permittees and the new permittees containing: 1) the legal name and address of the new owner; 2) a specific date for the effective transfer of permit responsibility, coverage and liability; and 3) a certification of the continuity of or any changes in operations, wastewater discharge, or wastewater treatment.

If the new permittees are proposing changes in operations, wastewater discharge, or wastewater treatment, the Department may propose modification of this permit in accordance with applicable laws and rules.

14. Operations and Maintenance Manual

For wastewater treatment facilities that serve the public (and are thus subject to Part 41 of the NREPA), Section 4104 of Part 41 and associated Rule 2957 of the Michigan Administrative Code allow the Department to require an Operations and Maintenance (O&M) Manual from the facility. An up-to-date copy of the O&M Manual shall be kept at the facility and shall be provided to the Department upon request. The Department may review the O&M Manual in whole or in part at its discretion and require modifications to it if portions are determined to be inadequate.

At a minimum, the O&M Manual shall include the following information: permit standards; descriptions and operation information for all equipment; staffing information; laboratory requirements; record keeping requirements; a maintenance plan for equipment; an emergency operating plan; safety program information; and copies of all pertinent forms, as-built plans, and manufacturer's manuals.

Certification of the existence and accuracy of the O&M Manual shall be submitted to the Department at least sixty days prior to start-up of a new wastewater treatment facility. Recertification shall be submitted sixty days prior to start-up of any substantial improvements or modifications made to an existing wastewater treatment facility.

15. Signatory Requirements

All applications, reports, or information submitted to the Department in accordance with the conditions of this permit and that require a signature shall be signed and certified as described in the Federal Act and the NREPA.

The Federal Act provides that any person who knowingly makes any false statement, representation, or certification in any record or other document submitted or required to be maintained under this permit, including monitoring reports or reports of compliance or noncompliance, shall, upon conviction, be punished by a fine of not more than \$10,000 per violation, or by imprisonment for not more than 6 months per violation, or by both.

The NREPA (Section 3115(2)) provides that a person who at the time of the violation knew or should have known that he or she discharged a substance contrary to this part, or contrary to a permit, COC, or order issued or rule promulgated under this part, or who intentionally makes a false statement, representation, or certification in an application for or form pertaining to a permit or COC or in a notice or report required by the terms and conditions of an issued permit or COC, or who intentionally renders inaccurate a monitoring device or record required to be maintained by the Department, is guilty of a felony and shall be fined not less than \$2,500.00 or more than \$25,000.00 for each violation. The court may impose an additional fine of not more than \$25,000.00 for each day during which the unlawful discharge occurred. If the conviction is for a violation committed after a first conviction of the person under this subsection, the court shall impose a fine of not less than \$25,000.00 per day and not more than \$50,000.00 per day of violation. Upon conviction, in addition to a fine, the court in its discretion may sentence the defendant to imprisonment for not more than 2 years or impose probation upon a person for a violation of this part. With the exception of the issuance of criminal complaints, issuance of warrants, and the holding of an arraignment, the circuit court for the county in which the violation occurred has exclusive jurisdiction. However, the person shall not be subject to the penalties of this subsection if the discharge of the effluent is in conformance with and obedient to a rule, order, permit, or COC of the Department. In addition to a fine, the attorney general may file a civil suit in a court of competent jurisdiction to recover the full value of the injuries done to the natural resources of the state and the costs of surveillance and enforcement by the state resulting from the violation.

16. Electronic Reporting

Upon notice by the Department that electronic reporting tools are available for specific reports or notifications, the permittees shall submit electronically all such reports or notifications as required by this permit, on forms provided by the Department.

PART II

Section D. Management Responsibilities

1. Duty to Comply

All discharges authorized herein shall be consistent with the terms and conditions of this permit. The discharge of any pollutant identified in this permit, more frequently than, or at a level in excess of, that authorized, shall constitute a violation of the permit.

It is the duty of the permittees to comply with all the terms and conditions of this permit. Any noncompliance with the Effluent Limitations, Special Conditions, or terms of this permit constitutes a violation of the NREPA and/or the Federal Act and constitutes grounds for enforcement action; for permit or Certificate of Coverage (COC) termination, revocation and reissuance, or modification; or denial of an application for permit or COC renewal.

It shall not be a defense for permittees in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

2. Operator Certification

The permittees shall have the waste treatment facilities under direct supervision of an operator certified at the appropriate level for the facility certification by the Department, as required by Sections 3110 and 4104 of the NREPA. Permittees authorized to discharge storm water shall have the storm water treatment and/or control measures under direct supervision of a storm water operator certified by the Department, as required by Section 3110 of the NREPA.

3. Facilities Operation

The permittees shall, at all times, properly operate and maintain all treatment or control facilities or systems installed or used by the permittees to achieve compliance with the terms and conditions of this permit. Proper operation and maintenance includes adequate laboratory controls and appropriate quality assurance procedures.

4. Power Failures

In order to maintain compliance with the effluent limitations of this permit and prevent unauthorized discharges, the permittees shall either:

- a. provide an alternative power source sufficient to operate facilities utilized by the permittees to maintain compliance with the effluent limitations and conditions of this permit; or
- b. upon the reduction, loss, or failure of one or more of the primary sources of power to facilities utilized by the permittees to maintain compliance with the effluent limitations and conditions of this permit, the permittees shall halt, reduce or otherwise control production and/or all discharge in order to maintain compliance with the effluent limitations and conditions of this permit.

5. Adverse Impact

The permittees shall take all reasonable steps to minimize or prevent any adverse impact to the surface waters or groundwaters of the state resulting from noncompliance with any effluent limitation specified in this permit including, but not limited to, such accelerated or additional monitoring as necessary to determine the nature and impact of the discharge in noncompliance.

6. Containment Facilities

The permittees shall provide facilities for containment of any accidental losses of polluting materials in accordance with the requirements of the Part 5 Rules (R 324.2001 through R 324.2009 of the Michigan Administrative Code). For a Publicly Owned Treatment Work (POTW), these facilities shall be approved under Part 41 of the NREPA.

7. Waste Treatment Residues

Residuals (i.e. solids, sludges, biosolids, filter backwash, scrubber water, ash, grit, or other pollutants or wastes) removed from or resulting from treatment or control of wastewaters, including those that are generated during treatment or left over after treatment or control has ceased, shall be disposed of in an environmentally compatible manner and according to applicable laws and rules. These laws may include, but are not limited to, the NREPA, Part 31 for protection of water resources, Part 55 for air pollution control, Part 111 for hazardous waste management, Part 115 for solid waste management, Part 121 for liquid industrial wastes, Part 301 for protection of inland lakes and streams, and Part 303 for wetlands protection. Such disposal shall not result in any unlawful pollution of the air, surface waters or groundwaters of the state.

8. Right of Entry

The permittees shall allow the Department, any agent appointed by the Department, or the Regional Administrator, upon the presentation of credentials and, for animal feeding operation facilities, following appropriate biosecurity protocols:

- a. to enter upon the permittee's premises where an effluent source is located or any place in which records are required to be kept under the terms and conditions of this permit; and
- b. at reasonable times to have access to and copy any records required to be kept under the terms and conditions of this permit; to inspect process facilities, treatment works, monitoring methods and equipment regulated or required under this permit; and to sample any discharge of pollutants.

9. Availability of Reports

Except for data determined to be confidential under Section 308 of the Federal Act and Rule 2128 (R 323.2128 of the Michigan Administrative Code), all reports prepared in accordance with the terms of this permit, shall be available for public inspection at the offices of the Department and the Regional Administrator. As required by the Federal Act, effluent data shall not be considered confidential. Knowingly making any false statement on any such report may result in the imposition of criminal penalties as provided for in Section 309 of the Federal Act and Sections 3112, 3115, 4106 and 4110 of the NREPA.

10. Duty to Provide Information

The permittees shall furnish to the Department, within a reasonable time, any information which the Department may request to determine whether cause exists for modifying, revoking and reissuing, or terminating this permit or the facility's COC, or to determine compliance with this permit. The permittees shall also furnish to the Department, upon request, copies of records required to be kept by this permit.

Where the permittees become aware that it failed to submit any relevant facts in a permit application, or submitted incorrect information in a permit application or in any report to the Department, it shall promptly submit such facts or information.

PART II**Section E. Activities Not Authorized by This Permit****1. Discharge to the Groundwaters**

This permit does not authorize any discharge to the groundwaters. Such discharge may be authorized by a groundwater discharge permit issued pursuant to the NREPA.

2. POTW Construction

This permit does not authorize or approve the construction or modification of any physical structures or facilities at a POTW. Approval for the construction or modification of any physical structures or facilities at a POTW shall be by permit issued under Part 41 of the NREPA.

3. Civil and Criminal Liability

Except as provided in permit conditions on "Bypass" (Part II.C.9. pursuant to 40 CFR 122.41(m)), nothing in this permit shall be construed to relieve the permittees from civil or criminal penalties for noncompliance, whether or not such noncompliance is due to factors beyond the permittee's control, such as accidents, equipment breakdowns, or labor disputes.

4. Oil and Hazardous Substance Liability

Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittees from any responsibilities, liabilities, or penalties to which the permittees may be subject under Section 311 of the Federal Act except as are exempted by federal regulations.

5. State Laws

Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittees from any responsibilities, liabilities, or penalties established pursuant to any applicable state law or regulation under authority preserved by Section 510 of the Federal Act.

6. Property Rights

The issuance of this permit does not convey any property rights in either real or personal property, or any exclusive privileges, nor does it authorize violation of any federal, state or local laws or regulations, nor does it obviate the necessity of obtaining such permits, including any other Department of Environment, Great Lakes, and Energy permits, or approvals from other units of government as may be required by law.

4. Process Overview

4.1 General Combined Sewer Overflow Facility Descriptions

The Great Lakes Water Authority (GLWA) operates and maintains nine combined sewer overflow (CSO) facilities. The primary function of the CSO facilities is to screen, settle, skim, and disinfect combined sewer/storm water during rain events before discharge to the receiving water body or return captured water to the Wastewater Resource Recovery Facility (WRRF) for further treatment. These CSO facilities play a vital role in keeping combined sewer water out of residents of the City of Detroit's basements and protecting public health and the environment. All facilities must meet discharge requirements contained in GLWA's National Pollutant Discharge Elimination System (NPDES) permit. Detailed facility descriptions are provided in the following sections.

There are two types of CSO facilities: Retention Treatment Basins (RTBs) and Screening and Disinfection Facilities (SDFs). Both facilities provide screening and disinfection. The RTB provides dedicated settling within a retention basin. The SDFs provide contact time for disinfection within effluent conduits prior to discharge to the river. The effluent conduits are up to 1 mile long.

Table 4-1 presents key design criteria and general information for each facility.

4.2 Project Overview

This project consists of three main activities, which consist of the following:

- Asset Management Planning (Scheduled Replacement Plan)
- Performance Based Planning (Facilities Assessment)
- 20-Year Capital Improvement and Capital Outlay Planning

The three main activities and their relationship is demonstrated in Figure 4-1 and described in Sections 4.2.1 through 4.2.3.

Table 4-1. Key Design Criteria and General Information for GLWA’s CSO Facilities

	Baby Creek	Belle Isle	Conner Creek	Hubbell Southfield	Leib	Oakwood	Puritan-Fenkell	Seven Mile	St. Aubin

Screen Type (size of slot or opening)	Perforated Plate (6-mm)	Perforated Plate (6-mm)	Bar Screen (1.5-inch)	Bar Screen (1.5-inch)	Raked Vertical and Horizontal Bar Screens (4-mm)	Perforated Plate (6-mm)	Bar Screen (0.5-inch)	Bar Screen (0.5-inch)	Raked Vertical Bar Screens (4-mm)
Disinfectant Type	Liquid Sodium Hypochlorite (NaOCl)								
Receiving Water Body	Rouge River	Detroit River	Detroit River	Rouge River	Detroit River	Rouge River	Rouge River	Rouge River	Detroit River

^a Treatment capacity refers to the design capacity of the screening and disinfection systems.

^b Based on Conner Creek Basis of Design report, the screening capacity is 13,963 cfs and disinfection capacity is 13,262 cfs.

^c Based on Hubbell Southfield O&M Manual, the disinfection capacity is 2,200 cfs. The screening capacity is not specifically listed and is assumed to be equal to the hydraulic capacity.

Notes:

cfs = cubic feet per second

MG = million gallon(s)

mm = millimeter(s)

N/A = not applicable

NaOCl = sodium hypochlorite

O&M = operation and maintenance

Figure 4-1. Relationship of Main Project Activities

4.2.1 Asset Management Planning (Scheduled Replacement Plan)

The Asset Management Planning (Scheduled Replacement Plan) is further described and the work was completed in Volume 3 – Asset Audit, Condition Assessment, FMEAs, and Scheduled Replacement Plan. This portion of the work focused on the existing GLWA CSO assets, populated asset information into GLWA's Computerized Maintenance Management System (CMMS) Oracle Work and Asset Management (WAM), gathered asset condition and depreciation information, and then utilized a mathematical model to determine when an asset should be replaced.

The Scheduled Replacement Plan (SRP) is an output of the SRP Model and is a listing of asset replacements and their costs over a 20-year planning period. The SRP utilizes the condition assessment results and asset information to calculate a scheduled replacement plan for each asset. The SRP information is then compared to the Facilities Assessment information to help make decisions on selection of Facilities Assessment alternatives, selected alternative implementation date, and possible bundling of alternatives into larger projects.

The SRP is strictly identifying when an asset should be replaced. This replacement is in-kind or with the current version, often the case of control systems. The SRP does not take into account future conditions such as regulatory change or increased/decreased flows. As shown in Figure 4-1, the SRP information is then coordinated with the Facilities Assessment to avoid duplication of budgets and to optimize bundling and scheduling of replacements and/or projects, while considering both existing and future asset needs.

The work completed in Volume 3 - Asset Audit, Condition Assessment, FMEAs, and Schedule Replacement Plan, specifically the SRP, is the first work completed within the overall CSO CS-299 project. This is the foundation of the condition and replacement of existing assets. This information will be pulled into Volume 2 – Facilities Assessment and used to optimize the overall delivery of existing asset replacement and Facilities Assessment projects. In this process, information in Volume 3 may become out of date if Volume 2 optimizes timing of the scheduled replacement of existing assets due to the Facilities Assessment. Therefore, Volume 3 information may not match the final information found in Volume 2.

4.2.2 Performance Based Planning (Facilities Assessment)

The Performance Based Planning (Facilities Assessment) is further described in this Volume 2 – Facilities Assessment. This portion of the work focuses on the current and future needs of the GLWA CSO Facilities such as improving Operations & Maintenance (O&M), increasing safety, standardizing equipment, anticipated flow requirements, and anticipated regulatory requirements.

Within the Facilities Assessment, site reviews of assets, interviews of O&M staff, and evaluation of current and reasonably anticipated future requirements of the CSO Facilities occurred. This resulted in a list of Facility Needs which should be addressed. Alternatives were developed to address these needs and generally include a Do Nothing alternative and one or more implementation alternatives. Each alternative was scored with non-economic benefit rankings and those benefits were compared to the Net Present Value (NPV) of the alternative. The NPV consists of the alternative's capital cost and annual operations and maintenance cost. The best value alternative consisted of the alternative with the lowest NPV/benefit ratio, which indicates the least amount of money required for the largest benefit.

Generally, the best value alternative was the selected alternative which moved on to Capital Improvement Plan (CIP) consideration. However, occasionally some alternatives had very similar NPV/benefit ratios or had external non-quantified benefits and therefore the best value alternative may not have been selected.

Once the Facilities Assessment alternatives were selected and a project identified, consideration of the accompanying assets from the SRP was completed. Some Facilities Assessment alternatives offered enhancements to existing assets or new assets and some alternatives offered replacement of existing assets. Therefore, consideration of the SRP was critical to avoid double budgeting of assets (replacement and needs) and to develop optimal bundling and scheduling of alternatives and projects to maximize the value of the existing assets. For example, the enhancement of a disinfection system should consider the condition of the existing disinfection system and, if appropriate, the enhancement implementation schedule should coincide with maximizing the life of the existing disinfection system.

The work completed in Volume 2 – Facilities Assessment, is the second phase of work completed with the overall CSO CS-299 project. This is the foundation of the facility performance needs and is impacted by the existing condition of assets and the scheduled replacement plan. Volume 2 – Facilities Assessment will optimize the facility needs and scheduled replacement plan and develop the 20-year CIP and 20-year Capital Outlay Plan on a Facility by Facility basis. This information will ultimately proceed to the Volume 1 – Project Information and Capital Improvement and Capital Outlay Plan.

4.2.3 20-Year Capital Improvement and Capital Outlay Planning

Following the development of the Facilities Assessment and SRP, individual CSO Facility 20-year CIPs and 20-year Capital Outlay Plans were created. This process is further described in this Volume 2 – Facilities Assessment report.

Projects for individual CSO Facilities were bundled and scheduled, and a 20-year CIP was developed. These nine 20-year CIPs are contained in this report in the following sections below. The intent of this report is to develop the nine individual CIPs.

Within the Facilities Assessment, a Capital Outlay Plan is developed for each CSO Facility. This plan was developed following the development of the specific CSO Facility CIP. Assets identified in the SRP, that are not being replaced in the Facilities Assessment selected alternatives, make it into the Capital Outlay Plan. Occasionally, a Facilities Assessment selected alternative may be of low complexity, low capital cost, and/or impacted with asset replacements and, therefore, may be included in the Capital Outlay Plan and not the CIP.

4.3 Purpose of Multi-Disciplinary Facilities Assessment

The purpose of this Multi-Disciplinary Facilities Assessment report is to document the identified improvements or needs at GLWA's nine CSO Control Facilities. A facility need is a required or desired improvement to meet current or anticipated changes to the CSO system such as regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease operation and maintenance (O&M).

Jacobs, in collaboration with GLWA staff, identified and evaluated these needs, developed total project capital costs, and provided information for needs prioritization through GLWA's business case evaluation process. The Facilities Assessment projects, along with projects from the Scheduled Replacement Plan (SRP), described further in the following section, will be incorporated into the CIP or Capital Outlay Plan.

4.4 Approach for Multi-Disciplinary Facilities Assessment

Jacobs Consultants, Inc (Jacobs) assembled a team of discipline-specific engineers to help identify and evaluate improvements at each CSO facility. The disciplines for this assessment included:

- Screening

- Disinfection
- Odor Control
- Flushing and Dewatering
- Heating, Ventilation, and Air Conditioning (HVAC) and Plumbing
- Electrical
- Instrumentation and Control (I&C)
- Site
- Architectural
- Safety
- Supporting Infrastructure
- Sanitary and Storm Pumping, if applicable

The needs were identified through the following activities:

- Review of the Wastewater Master Plan (WWMP) for any planned increased/decreased flows at each facility and the potential need for increased facility capacity or modified operation (i.e., RTBs converted to capture-only basins). The WWMP was completed by CDM Smith Inc. in 2020.
- Discipline-specific meetings with GLWA CSO O&M staff to obtain input on needs and issues within the facilities
- Observations during site visits by Jacobs team staff members
- Review of maintenance work orders from WAM
- Review of supervisory control and data acquisition (SCADA) data
- Review of original equipment manufacturer (OEM) condition assessments conducted under CS-299
- Projects to address the identified needs and issues were developed with two or more alternatives. The approach for alternatives evaluation is described in Section 4.7.

4.5 Organization of Multi-Disciplinary Facilities Assessment

The Multidisciplinary Facilities Assessment is organized by facility (in alphabetical order of facility name). The Facilities Assessment starts at Section 4. Section 4 provides the process overview for the Facilities Assessment and how the work was performed. Section 5 provides the evaluation of issues that are common to multiple facilities, such as standardized chemical feed system replacement. In an effort to reduce repetition, these issues are described once in this section and referred to in the facility-by-facility assessments, where applicable.

Sections 6 through 14 include the facility-by-facility assessment of needs. For each facility assessment, the needs are addressed by discipline in the order presented in Section 4.4.

4.6 Coordination with Scheduled Replacement Plan

In conjunction with the Multi-Disciplinary Facilities Assessment, Jacobs reviewed existing WAM data, as-built record drawings, O&M manuals, and met with GLWA O&M staff to identify assets, develop an asset hierarchy, and populate WAM with updated or new asset information. With current asset information established, GLWA and Jacobs collaboratively identified how condition assessments would be performed, either visually or detailed. The visual condition assessment was performed whether the asset was operating or not. Therefore, this was a less intensive condition assessment and a method commonly employed on lower risk assets. The detailed condition assessment was performed on operating assets and, depending on asset type, included such items as vibration, temperature, voltage, and amperage.

Jacobs performed onsite visual and detailed condition assessments of approximately 3,200 assets. This resulted in an asset condition score of 1 through 5, with 1 being nearly new and 5 being extremely poor or not operating. Utilizing the asset condition score, along with additional asset information such as useful life, install date, and replacement cost, Jacobs was able to calculate the asset's scheduled replacement.

The SRP consists of all the CSO assets and their calculated individual replacement date and costs. While a robust SRP following Asset Management best practices is highly important to balance asset risk and expenditures, the SRP process has a very limited ability to address future needs, such as those mentioned above and consisting of regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease O&M.

The SRP process and the Multi-Disciplinary Facilities Assessment report need to be coordinated to avoid excessive expenditures as well as balancing the upgrading of good condition assets. Once the Multi-Disciplinary Facilities Assessment projects are identified, projects that are directly impacting existing assets will be noted and linked to the asset. This will pull all information together so that GLWA staff and Jacobs can develop the prioritized projects for the CIP. For example, see Table 4-2, which demonstrates how decisions might be made based on the Facilities Assessment and SRP information.

Table 4-2. Example of Facilities Assessment and SRP Interaction

Facilities Assessment		Scheduled Replacement Plan		Recommendation
Description	Need Date	Condition	Replacement Date	
Project No. 1	2021	2	2035	Implement Facilities Assessment Project
Project No. 2	2025	5	2021	Implement SRP Project
Project No. 3	None Identified	3	2024	Implement SRP Project

The prioritization of the Facilities Assessment and SRP projects into the CIP may result in some assets in good condition being replaced early as in Project No. 1 above or some Facilities Assessment projects being implemented sooner based on corresponding poor condition assets such as in Project No. 2. The Facilities Assessment and SRP coordination process will be a manual and iterative process, however it is benefited by the work being completed concurrently.

Finally, Project No. 3 illustrates a project or asset that is not included in the Facilities Assessment and will ultimately be replaced as part of the SRP. As such, the intent of the Facilities Assessment is not to evaluate the replacement of every asset, especially those that will be replaced in-kind. Rather, the Facilities Assessment focuses on those needs associated with new regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease O&M.

4.7 Alternatives Evaluation Approach

Once needs were identified, projects were developed, and each project consisted of several types of alternatives for consideration:

- Do Nothing Alternative – replace existing assets in-kind or do not add enhancement assets
- Improvement Alternative – replace/improve existing assets with new technology or approach (includes standardization). This alternative is benefited by a comparison to the Do Nothing alternative which includes existing asset information.

- Improvement Alternative – enhance existing facility performance by adding new assets. This alternative is not benefited by a comparison to the Do Nothing alternative.

4.7.1 NPV/Benefit Ratio

To evaluate alternatives, a best value approach was established. This approach considers the non-economic benefit scoring of each alternative along with the economic Net Present Value (NPV) of each alternative. Then the ratio of NPV to benefit can be determined and an alternative with the lowest NPV/benefit ratio, is the best value alternative.

The non-economic benefits that were considered include:

- Benefit #1 – Health and Safety
- Benefit #2 - Water Quality and Compliance
- Benefit #3 – Capacity Enhancement
- Benefit #4 - Component Performance
- Benefit #5 - O&M Ease

These non-economic benefits were ranked on a scale of 1 to 5 for each benefit and each alternative, with the least benefit being 1 and greatest benefit being 5. When considering the benefit score, the actual number is not as important as the relationship of the scores between alternatives. For example, an alternative that has a significantly greater benefit should be scored accordingly with regards to other alternatives.

The NPV is determined by understanding the alternatives immediate capital cost along with the projected annual O&M cost. For several projects, the differential in O&M costs between alternatives is negligible so for simplicity, the alternatives did not include O&M costs in the NPV, as it would not change the results of the best value alternative.

This best value alternative works very well to defend and justify project alternative selections. However, occasionally additional external factors or the scale of the NPV versus the scale of the non-economic benefits do not align which results in the NPV/benefit ratio not being the best method of selecting an alternative. In those cases, engineering judgement and knowledge of the CSO facility and needs were utilized to select an alternative.

4.7.2 Do Nothing Alternative

Alternatives generally consisted of improvements to the facility but also considered a Do Nothing alternative. The Do Nothing alternative typically consists of pulling the SRP information for the existing assets associated with the Facilities Assessment project. This information contains total replacement costs of the associated assets. The Do Nothing alternative was then given benefit and NPV scores, and an NPV/benefit ratio was developed and considered against improvement alternatives.

Comparing the NPV/benefit ratios of the Do Nothing alternative against the improvement alternatives helped guide the selection of the best value alternative. In some cases, the improvement alternative was selected and, in some cases, the Do Nothing alternative.

Occasionally the Do Nothing alternative did not relate to existing assets as the project was based strictly on adding new assets. In these cases, the Do Nothing alternative did not have costs or an NPV/benefit ratio and, therefore, a best value alternative was not determined. However, the improvement alternative may have been selected when comparing its NPV/benefit ratio to other alternatives throughout this process and when considering external factors.

The SRP also pulls the information listed below (this information is pulled by assigning the Facilities Assessment project number, for example "BC-DIS-1", to the appropriate assets in the SRP):

- Total number of assets selected
- Maximum Consequence of Failure score of the selected assets
- Average Consequence of Failure score of the selected assets
- Maximum Condition Score of the selected assets
- Average Condition Score of the selected assets
- Maximum Risk Score of the selected assets
- Average Risk Score of the selected assets
- Average Life Expectancy of the selected assets
- Average Replacement Date (based on the condition score) of the selected assets
- Total Replacement Cost of the selected assets

The information listed above for the Do Nothing alternative is extremely helpful in determining the scheduling of projects. For example, when considering the standardization of a chemical feed system, the improvement alternative selected may suggest standardizing the chemical feed system. Then, when considering the asset information of the existing chemical feed system, it may be determined that the existing chemical feed system is projected to reach the end of its useful life in a few years and that time may be the optimal time for chemical feed system standardization.

4.7.3 Improvement Alternative

The improvement alternative typically consists of 1) replacing/improving existing assets with a new technology/ approach or 2) enhancement of the existing facility performance through the addition of new assets.

4.8 Capital Improvement Plan and Capital Outlay Plan Approach

The 20-year CIP and 20-year Capital Outlay Plan approach consists of projects for all nine CSO facilities that are to be debt financed (CIP) or revenue/cash financed (Capital Outlay). The CIP projects generally consists of improvements identified in the Facilities Assessment while the Capital Outlay Plan generally consists of the SRP assets.

4.8.1 Capital Improvement Plan Process Overview

The development of the 20-year CIP is based on the results of the Asset Audit, Asset Condition Assessments, SRP, and the Facilities Assessments. While all of this information influenced the development of the CIP, the greatest influencer is the Facilities Assessments and selected implementation alternatives.

Within the Facilities Assessment, site reviews of assets, interviews of O&M staff, and evaluation of current and reasonably anticipated future requirements of the CSO Facilities occurred. This resulted in a list of Facility Needs which should be addressed. Alternatives were developed to address these needs and generally include a Do Nothing alternative and one or more implementation alternatives. Each alternative was scored with non-economic benefit rankings and those benefits were compared to the Net Present Value (NPV) of the alternative. The NPV consists of the alternative's capital cost and annual O&M cost. The best value alternative consisted of the alternative with the lowest NPV/benefit ratio, which indicates the least amount of money required for the largest benefit.

Generally, the best value alternative was the selected alternative which moved on to CIP consideration. However, occasionally some alternatives had very similar NPV/benefit ratios or had external non-quantified benefits and therefore the best value alternative may not have been selected.

Once the Facilities Assessment alternatives were selected and a project identified, consideration of the accompanying assets from the SRP was completed. Some Facilities Assessment alternatives offered enhancements to existing assets or new assets and some alternatives offered replacement of existing assets. Therefore, consideration of the SRP was critical to avoid double budgeting of assets (replacement and needs) and to develop optimal bundling and scheduling of alternatives and projects to maximize the value of the existing assets. For example, the enhancement of a disinfection system should consider the condition of the existing disinfection system and, if appropriate, the enhancement implementation schedule should coincide with maximizing the life of the existing disinfection system.

4.8.2 Capital Outlay Plan Process Overview

The development of the 20-year Capital Outlay Plan is based on the results of the Asset Audit, Asset Condition Assessments, SRP, and the Facilities Assessments. While all of this information influenced the development of the Capital Outlay Plan, the greatest influencer is the SRP.

Within the Facilities Assessment, a Capital Outlay Plan was developed for each CSO Facility. This plan was developed following the development of the specific CSO Facility CIP. Assets identified in the SRP, that are not being replaced in the Facilities Assessment selected alternatives, make it into the Capital Outlay Plan. Occasionally, a Facilities Assessment selected alternative may be of low complexity, low capital cost, and/or impacted with asset replacements and therefore may be included in the Capital Outlay Plan and not the CIP.

4.9 Capital Cost Estimating Approach

Capital cost estimates were developed for capital improvement projects presented in this Facilities Assessment and for SRP projects (i.e., replace in-kind).

4.9.1 Capital Improvement Project Costs

Capital improvement projects represent those projects that would likely require design and construction assistance by a Professional Engineer and installation/construction by a Contractor. Capital cost estimates (included in Volume 6 – Appendices, Appendix C for all Facilities Assessment projects) used a uniform template with individual construction costs for major components of the project and then typical percentages for planning, design services, services during construction, additional project costs for the contractor, and design and construction contingencies. The total cost presented for each project represents a Total Project Cost. A summary of the cost categories and the associated source of costs is included in Table 4-3.

Table 4-3. Cost Categories for Capital Cost Estimating

Cost Category	Description	Method for Cost Generation
Project Definition, Planning and Preliminary Design	Represents costs for professional services to develop the project definition, planning and preliminary design concepts. Typically, this information would be used in development of the Design Services procurement documents. Budget for this scope is provided for every project, however GLWA staff may choose to complete this scope internally at minimal cost.	5% of Total Construction Cost

Cost Category	Description	Method for Cost Generation
Design Services	Represents costs for professional design services to produce contract documents that can be bid by a Contractor.	The cost of this service is based on a percentage inversely proportional to the total construction cost, with a higher percentage for lower cost projects and a lower percentage for higher cost projects.
Non-Construction Contingency	Contingency for the design phase to include unforeseen issues that need to be included in the design or be evaluated during design.	15% of Total Construction Cost for most projects.
Services During Construction	Represents costs for professional services that are not covered by GLWA staff to provide construction administration services, including submittal reviews, Requests for Information (RFIs), field inspection, material testing, etc.	Similar to Design Services, the cost of this service is based on a percentage inversely proportional to the total construction cost with a higher percentage for lower cost projects and a lower percentage for higher cost projects.
Total Construction Cost	Represents the cost for a Contractor to perform the work, assuming a Design/Bid/Build type of project delivery.	Sum of Project Cost of Work and Additional Project Cost for Construction.
Project Cost of Work	This cost represents the costs for the material, labor, and equipment to construct the scope of work.	Based on vendor quotes, Jacobs construction cost estimating software, and experience.
Additional Project Cost for Construction	Represents the additional costs of the Contractor to manage and deliver the scope of work. Also includes Construction Contingency based on Final Design.	▪ Contractor Overhead – 8% (of Project Cost of Work, typical for all costs in this category) ▪ Contractor Profit – 5% ▪ General Conditions – 10% ▪ Mobilization/Demobilization – 5% ▪ Insurance – 2% ▪ Performance Bond General – 1% ▪ Performance Bond Electrical – 1%
Construction Contingency Based on Final Design	Contingency (30% for most projects) to cover ancillary items not included in the line item costs and unforeseen conditions that are not known in the project planning phase.	30% of Project Cost of Work for most projects
Total Project Cost		Sum of the Project Definition, Planning & Preliminary Design, Design Services, Services During Construction and the Total Construction Costs

The Total Project Costs represent Class 4 estimates, as defined by the Association for the Advancement of Cost Engineering (AACE) International. The expected range of costs is -30% and +50% from the median value. It should be noted that in providing opinions of cost for projects, Jacobs has no control over performance of third party engineers/contractors; cost or price of labor and materials; unknown or latent conditions of existing equipment or structures that may affect operation or maintenance costs; competitive bidding procedures and market conditions; time or quality of performance by operating personnel or third parties; and other economic and operational factors that may materially affect the ultimate project cost or schedule. Therefore, Jacobs makes no warranty that the actual project costs will not vary from Jacobs opinions or estimates of cost.

4.9.2 Scheduled Replacement Plan Asset Replacement Costs

Replacement costs are provided for every asset in the CSO WAM database. These costs are used to provide capital costs in the SRP. The costs are intended to represent installed costs for the in-kind (or latest version) replacement of each asset. To populate these costs, Jacobs used previously generated costs from the 2013 SRP project (inflated to 2021 dollars), which included costs from Schedule of Values from the original construction project for the CSO basins. Where costs were not available, Jacobs obtained costs from construction cost estimating software or vendor quotes. Table 4-4 provides the mark-ups applied to the unit costs to generate the total replacement cost for each asset.

Table 4-4. Cost Categories for SRP Replacement Costs

Cost Category	Method of Cost Generation
Replacement Cost (including installation)	Previous SRP Replacement costs (inflated to 2021 dollars), construction cost estimating software, and vendor quotes
Engineering and Contingency	30% of replacement cost
Contractor Overhead and Profit	15% of replacement cost

5. Common Needs Among Multiple Facilities

5.1 Introduction

This section provides the evaluation of needs that are common or similar among multiple or all facilities. Disciplines with common needs include Disinfection, Electrical, Instrumentation and Controls (I&C), Structural, and Safety. To reduce repetition, these issues are described once in this section and referred to in the facility-by-facility assessments, where applicable. The review of past Maintenance Work Orders for all assets is included at the end of this section.

5.2 Disinfection

5.2.1 Overview and Review of Current Disinfection Performance

This section describes needs related to disinfection that are common among multiple facilities. Common needs for the disinfection systems at each facility include:

- 1) Replacement of Chemical Feed Systems
- 2) Provide Flow-Paced and Total Residual Chlorine (TRC)-Paced Automatic Chemical Feed
- 3) Reduce Costs Associated with Large Quantity of Chemical Induction Mixers

Table 5-1 provides a summary of the disinfection system at each CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G. Table 5-2 provides a summary of the sodium hypochlorite pumps and capacities at each facility.

Table 5-1. Overview of Disinfection Systems

Facility	Type	Install Date	Disinfection System Design Storm Flow (cfs)	Disinfectant Used	Design Feed Strength (% Hypo.)	Max. Dosage at Design Flow (mg/L Cl ₂)	No. of Storage Tanks	Total Vol. of Storage Tanks (gal)	Storage Tank Material	Type of Mixing at Feed Point	Contact Time (min)	No. of Mixers	Model Number/ hp	Manufacturer
Baby Creek	SDF	2006	5,100	Sodium hypochlorite	5	20	4	144,000	Rubber-lined steel	Chemical induction mixers	10	32	SWC15XPL 15 hp	Water Champ
Belle Isle	RTB	2007	33	Sodium hypochlorite	6-8	25	2	2,668	FRP	Chemical induction mixers	10	4	SWC15XP 15 hp	Water Champ
Conner Creek	RTB	2005	13,262	Sodium hypochlorite	10	25	4	380,000	Rubber-lined steel	Chemical induction mixers	5	60	SWC20XP 20 hp	Water Champ
Hubbell-Southfield	RTB	1996	2,200	Sodium hypochlorite	5	10	2	30,000	FRP	Chemical induction mixers	20	3	Series 32 25 hp	Gas Mastrrr
Leib	SDF	2002	1,550	Sodium hypochlorite	7.5	38	2	20,900	FRP	Chemical induction mixers	10	18	SWC15FX 15 hp	Water Champ
Oakwood	RTB	2012	1,660	Sodium hypochlorite	7.5	12	2	23,000	FRP	Diffuser ring	6 w/ 1 basin, 12 w/ 2 basins in service	Hypo added to pump discharge	N/A	N/A
Puritan-Fenkell	RTB	1996	845	Sodium hypochlorite	5	10 @ 845 cfs	2	8,000	FRP	Chemical induction mixers	20	2	SWC5R 5 hp	Water Champ
Seven Mile	RTB	1996	655	Sodium hypochlorite	5	10 @ 655 cfs	2	4,800	FRP	Chemical induction mixers	30	1	Series 32 10 hp	Gas Mastrrr
St. Aubin	SDF	2002	250	Sodium hypochlorite	10	38	2	10,400	FRP	Chemical induction mixers	10	7	SWC7.5FX 7.5 hp	Water Champ

Notes:
% = percent
Cl₂ = chlorine
FRP = fiber-reinforced plastic
hp = horsepower
mg/L = milligram(s) per liter

Table 5-2. Hypochlorite Pump Summary

Facility	Disinfection System Design Storm Flow (cfs)	No. of Pumps	Type of Pump	Capacity of Pump (gpm)	Manufacturer	Drive Type
Baby Creek	5,100	8 Total 2 low-rate 3 mid-rate 3 high-rate	Centrifugal	Low-rate: 0-50 Mid-rate: 0-150 High-rate: 0-400	Corcoran	VFD
Belle Isle	33	3	Diaphragm	10.4	Milton Roy	Adjustable stroke length and speed
Conner Creek	13,262	10	Centrifugal, magnetic drive	197	ITT Goulds Company	Constant speed
Hubbell-Southfield	2,200	5	Gear	10-55	Pulsafeeder (w/ standard coupler/drive)	VFD
Leib	1,550	8 Total 6 low-rate 2 high-rate	Low-rate: Diaphragm High-rate: Centrifugal	Low-rate: 7.6 High-rate: 112	Low-rate: Pulsa Series High-rate: Goulds	VFD
Oakwood	1,660	10 (3 low-rate, 7 high-rate)	Gear	Low-rate: 0-26 High-rate: 1.0-51	Pulsafeeder (with magnetic coupler/drive)	VFD
Puritan-Fenkell	845	4	Gear	20	Liquiflo	VFD
Seven Mile	655	4	Gear	20	Pulsafeeder (w/ standard coupler/drive)	VFD
St. Aubin	250	5 (2 low-rate, 3 high-rate)	Hydraulic diaphragm	Low-rate: 7.6 High-rate: 22.8	Pulsafeeder	VFD

Notes:
gpm = gallon(s) per minute
VFD = variable-frequency drive

NPDES Permit Requirements: The NPDES Permit No. M10022802 contains limits for fecal coliform and goals for TRC for all the CSO facility discharges. The permit specifies event maximum limits for fecal coliform bacteria of 400 counts (cts)/100 milliliter (mL) during the summer and 1000 cts/100 mL during the winter. The event maximum is reported as the geometric mean of all samples taken during an event, provided that three or more samples are collected.

The goals for TRC minimization are to "...operate the CSO retention treatment basins and CSO screening and disinfection facilities in a manner which will provide consistent, effective disinfection while minimizing the discharge of TRC...". The permit specifies operation goals for effluent TRC concentrations of 1.5 mg/L as an event average value and 2.0 mg/L (November 1 – April 30 or "winter") or 3.0 mg/L (May 1 – October 31 or "summer") as event instantaneous maximum values.

The permit defines that an "event" starts when combined sewage is discharged into a facility and ends when effluent flow ceases and does not resume within 24 hours. During an event, grab samples for effluent fecal coliform and TRC are collected every two hours for the first six hours of the discharge and every four hours thereafter for the duration of the discharge. For TRC, the average of all samples in an event is the "Event Average" and the maximum individual sample in an event is the "Event Maximum". On multiday events, the pollutant concentrations for the event are reported on the day the discharge event ends.

Historical Facility Disinfection Performance: Historical facility performance related to disinfection performance from 2016 through 2018 is presented in Volume 6 – Appendices, Appendix D. There are two graphs for each facility:

- 1) Daily Maximum Effluent TRC concentrations
- 2) Effluent Fecal Coliform and Average TRC concentrations

Effluent performance was assessed by comparing the reported event geometric mean fecal coliform concentrations to permit limits and the reported maximum and average TRC measurements to the permit operation goals. Upon review of the TRC data, it was apparent that the measurements were *daily* average and maximum measurements, rather than *event* average and maximum values. Additionally, there were several instances when the recorded maximum TRC value was less than the recorded average TRC value. In such cases, the dataset provided was checked against the Daily Monitoring Reports submitted to Environment, Great Lakes, and Energy (EGLE), and it was determined that the recorded values were simply switched. These errors were corrected by listing the greater value as the daily maximum measurement and the lesser value as the daily average measurement.

A summary of the findings and observations from this evaluation are provided in the following list:

- 1) The fecal coliform limit is typically met for every event, with a few exceptions. The facilities exceeding the limits and the corresponding number of times were as follows: Conner Creek (1), Leib (1), St. Aubin (2), and Baby Creek (2).
- 2) The summer and winter maximum effluent TRC goals of 2 and 3 mg/L are typically met. The SDFs appear to have slightly higher maximum values than the RTBs.
- 3) The operational goal for average TRC of 1.5 mg/L is typically exceeded for all facilities that discharge. This is likely due to the variable nature of CSO influent water quality, the fact that the operators first priority is to achieve permit compliance for fecal coliform, and the lack of automated chemical feed pacing.
- 4) There was no discharge from Puritan-Fenkell or Seven Mile during this period, therefore, the figures indicate "No Data Collected."

5.2.2 Replace Chemical Feed System

5.2.2.1 Introduction

Based on GLWA personnel input and observations during the site visits, the chemical feed systems at most of the facilities are in need of replacement to address one or more of the following:

- Replace aging, unreliable, and/or expensive to maintain chemical feed pumps and mixers
- Address inaccessible valves and appurtenances due to overly complex flow distribution schemes, and poorly laid out piping
- Increase turndown to not overdose during the more typical storm events while providing capacity for the infrequent peak instantaneous design storm flows
- Simplify the chemical feed system to improve manual operations should automated components be unavailable
- Ensure appropriate flow splitting to multiple mixers and diffusers in a given mixing zone including:
 - Replace old and unreliable back pressure valves to each mixer and diffuser
 - Provide a means of measuring pressure to verify back pressure valves are functioning properly and set equally
 - Provide flow indication for visual verification that flow is occurring to each location.

Additional facility specific needs are discussed in the facility-by-facility evaluation in the following sections. The evaluation and identification of chemical feed system alternatives for each facility are presented here and referenced in the facility-by-facility section because this section applies to most facilities.

5.2.2.2 Chemical Feed System Sizing

Based on GLWA observations and historical storm events, the chemical feed systems are generally oversized. The conservative sizing of chemical feed pump capacities is a result of the original facility design storm flows being greater than what has been observed as well as conservative assumptions on the required chlorine dose to meet permit fecal coliform requirements. Turndown of the oversized chemical feed system is exacerbated at Conner Creek where reliability issues with isolation gates results in flow being distributed across all bays regardless of how small the wet weather event is. The lack of isolation gates into the mixing zones results in a similar situation at Leib. Oversized chemical feed systems make it difficult to control dosing during smaller events. This increases the risk of exceeding the operational goals for TRC. Relevant information from past CSO facility studies was considered for sizing the chemical feed pumps for purposes of developing a capital cost budget.

The CSO facilities were originally designed based on modeled peak flow for a 10-year recurrence, 1-hour rainfall. Although continuous flow measurement records are not available, the design capacity at most or all of the facilities has never been reached based on available flow data and observations by GLWA personnel. Collection system modeling tools have improved since the modeling used for the design of these facilities. The most recent design storm results were obtained from the December 2019 Existing Conditions version of the Regional Wastewater Collection System model developed for the 2019 GLWA WWMP. The current predicted 10-year, 1-hour storm flows and the ratio of those flows as a percent of the original design flows are presented in Table 5-3.

Table 5-3. Comparison of Original and Current Predicted CSO Facility Design Storm Peak Flow Rates (10-Year, 1-Hour Flow Rates)

Facility	BC	BLI	CON	HS	Leib	OKW	PF	SM	STA
Original Predicted Facility Design Storm Peak Flow (cfs)	5,100	33	13,262	3,000 ^a	1,550	1,660	655 ^a	493 ^a	250
Current Predicted Facility Design Storm Peak Flow (cfs)	1,661	37	2,569	1,501	194	475	136	82	235
Ratio of Current to Originally Predicted Storm Flows (%)	33%	111%	19%	Not a comparable storm comparison	13%	29%	Not a comparable storm comparison	Not a comparable storm comparison	94%

^a The O&M manual provides the "10-year" Design Flow for 3.5 inch storm. It is assumed this is the 10-year, 24-hour storm event, since the 10-year, 1-hour storm is about 1.8 inches.

For the larger facilities with comparable design storms (i.e., Baby Creek, Conner Creek, Leib, and Oakwood) the predicted flows are less than half what was predicted for the same storm event when the facilities were designed. The generally lower flow predictions are partially explainable by:

- Recently modeled flows are in terms of peak hour while the original modeled flows were a shorter time increment
- The percent imperviousness of many of the service areas has decreased, thus contributing to less runoff
- More conservative assumptions in the original model

However, two concerns prevent revising the chemical feed system sizing based on the recent 10-year 1-hour modeling as follows:

- 1) There have been issues calibrating the model predicted flows to actual measured flows from storm events
- 2) The model predicted flows are less than past observed peak hour flows

At Conner Creek, which is the largest facility, the recently modeled 10-year 1-hour flow is only 19 percent of the original modeled flow. This would indicate that the facility is significantly oversized. However, the WWMP evaluated the flow distribution of 78 storms, 25 from 2005 to January of 2008 from the "Conner Creek CSO Basin Final Evaluation Report", and 53 from 2010 to 2014 discharge records, and found the peak flow at Conner Creek was 8,600 cfs and the average peak flow was 2,600 cfs. Thus, the modeled peak 10-year 1-hour event of 2,569 cfs was essentially equal to the average peak flow and significantly less than the historical peak from the 78 storms analyzed. The 8,600 cfs peak flow identified in the WWMP corresponds to 65 percent of the facility's design capacity. Based on the years analyzed, it would appear that the original design capacity of Conner Creek is overly conservative. However, the more recent modeled peak 10-year 1-hour flow does not appear to be conservative enough. Unfortunately, complete flow data is not available for the last 10 years at the CSO facilities to allow evaluation of the peak 10-year flow. Due to the absence of historical data and the fact that the recently modeled 10-year 1-hour event does not appear sufficiently conservative for design of disinfection facilities, the original facility design capacities will be used for sizing the chemical feed systems for capital budgeting. As additional flow data

becomes available with upgrades to flow measurement and recording, more modeling calibrated to actual flows could be considered during design to avoid oversizing the chemical feed system.

The selected design dose is also important to chemical feed system sizing. The original design doses vary from 10 mg/L as Cl_2 to 38 mg/L between CSO facilities. Experience at other CSO facilities indicates that the high doses assumed at some facilities are overly conservative considering both the improbability of needing the peak dose concurrent with peak flow when fecal coliform concentrations are likely diluted, and test data that would indicate diminishing disinfection benefits above certain doses.

For this evaluation under CS-299, a dose of 20 mg/L was assumed for all facilities except St. Aubin. A dose of 25 mg/L was assumed for St. Aubin because this facility had the highest average dose for the four largest storms evaluated from 2016 through 2018 and because a relatively recent report by another consultant assumed 24 mg/L. However, it is suspected that the higher dosing at St. Aubin was a result of turndown issues and lack of an automated control system and thus conservative. In addition, planning and budgeting for St. Aubin's disinfection system is not required because there is an ongoing design by another consultant at St. Aubin. Therefore, dosing requirements at St. Aubin are not further evaluated in this Facilities Assessment. The dose assumptions are believed to be sufficiently conservative for sizing the chemical feed systems for capital budgeting, especially when used in conjunction with the design peak flow rate. It may be appropriate to assume less conservative doses during design because oversizing the chemical feed system can lead to turndown issues for typical storm events.

The third most significant factor affecting chemical feed system sizing is the sodium hypochlorite strength. The sodium hypochlorite strength can vary either due to degradation or intentional dilution of a new delivery of sodium hypochlorite done to slow the degradation of sodium hypochlorite. The degradation of sodium hypochlorite is unique compared to most other chemicals used in wastewater treatment. The lower the sodium hypochlorite strength the larger the chemical feed system needs to be. The sodium hypochlorite strength is important because twice the feed rate is required for the same TRC if the sodium hypochlorite has degraded from 10 percent to 5 percent. An evaluation of sodium hypochlorite strength reported in recent years for the CSO facilities indicates that the strength has dropped to as low as 2 to 3 percent for all facilities that data was available, except Conner Creek. At Conner Creek the lowest reported strength was 5 percent. The hypochlorite strength has such a significant impact on sizing the chemical feed system that it is important to develop and abide by a policy of replacing the hypochlorite when the strength drops below a certain value. Depending on the quantity stored, this may be achieved by ordering a new delivery and mixing the low strength hypochlorite with the new full strength (e.g., typically on the order of 12.5 percent) hypochlorite. However, if the volume stored will excessively reduce the strength of a new delivery it would be necessary to dispose of the excess hypochlorite. Careful management of hypochlorite can be practiced to minimize the latter. For this evaluation under CS-299, a value of 5 percent was assumed as the minimum strength that sodium hypochlorite would be managed to for sizing the chemical feed pumps for purposes of developing a capital cost budget.

The assumed pump sizing is dependent on the sodium hypochlorite distribution approach and is thus presented in Section 5.2.2.4.

5.2.2.3 Chemical Feed System Pump Type

It is recommended that the existing pumps be replaced with either hose pumps (referred to as peristaltic pumps for smaller sizes) or magnetic drive centrifugal pumps. The advantages and disadvantages of these two types of pumps are noted in the following paragraphs. The final decision between the recommended types of pumps shall be determined during design. The preferred type of pump may also depend on what alternative is selected for flow distribution of sodium hypochlorite.

Hose Pumps: The advantages of hose pumps are listed in the following bullets:

- High turndown: With a totally enclosed non-ventilated motor and 60:1 variable-frequency drive (VFD), the hose pump maximum and minimum acceptable revolutions per minute (rpms) become the limiting factor. Higher than 20:1 turn down can be achieved by designing around atypically high rpms for the design peak flow storm events if this condition is expected to be rare. Turndowns on the order of the 60:1 VFD turndown may be possible by this approach.
- Positive displacement for accurate and repeatable metering
- Self-priming and suction lift capability of up to 30 ft thereby allowing full tank drawdown and allowing the pumps to be elevated on pads for spill protection
- Can pump air during priming, and sodium hypochlorite off-gassing will not bind the pump
- Hoses readily available for sodium hypochlorite (common application)
- No seals, diaphragms, glands, or exposed components to leak, corrode, or replace
- Eliminates need for check valves, seal water flush systems, and run-dry protection
- Standard parts (hose, bearings) for rehab

The disadvantages of hose pumps are listed in the following bullets:

- Higher initial cost than some other pumps
- Requires hose replacement
- Requires pulsation dampener which GLWA has had O&M issues with elsewhere
- If a hose wears through or bursts before replacement, then components of the pump will be exposed to the corrosive sodium hypochlorite
- Requires bumping the pumps per manufacturer's suggested schedule when idle (i.e., during dry weather and spare pumps) because the rollers compressing a fixed point of the hose for an extended period of time reduces hose life

The largest hose pump offered by Bredel is rated for 317 gallons per minute (gpm) continuous duty.

Magnetic Drive Centrifugal Pumps: The advantages of magnetic drive centrifugal pumps are listed in the following bullets:

- Generally lower initial cost than most pumps suitable for sodium hypochlorite
- Smaller footprint for the capacity than most pumps suitable for sodium hypochlorite
- Magnetic drive eliminates seals and leaks from drive shaft
- Centrifugal pumps are generally low maintenance
- GLWA has favorable experience using this type of pump at Conner Creek
- Eliminates need for pulsation dampeners
- Depending on the flow and head condition, higher capacities generally available compared to hose pumps

The disadvantages of magnetic drive centrifugal pumps are listed in the following bullets:

- Significantly less turndown than a positive displacement pump. This can result in the need for more pumps and potentially pumps of different sizes to cover the required range of flows.

- Not self-priming and less suction lift capability than a positive displacement pump. Therefore, these pumps cannot be elevated above the bottom of the tank as much as self-priming pumps for spill protection, and these pumps may not be able to draw a tank down to empty without supplemental priming provisions. The latter issue adds components and complexity and may decrease reliability. Although there are some self-priming models available, there are far fewer offerings than the standard non-self-priming sizes to cover the required range of flow and head conditions.
- Requires some appurtenances not required with a hose pump (e.g., check valves).
- Cannot run dry.
- Possibility of cavitation.

5.2.2.4 Sodium Hypochlorite Distribution Approach

In conjunction with pump replacement, it is recommended that the piping be replaced, and that the new piping be simplified compared to the current arrangement. Reasons for piping replacement include overly complex piping layouts, inaccessible valves and appurtenances, and failing joints in some facilities (e.g., Baby Creek). It is recommended that piping to and from the pumps be as simple as possible while maintaining necessary flexibility. Adding additional flexibility that is unlikely to be used adds complexity including additional valves to be exercised, the need for additional pressure relief valves wherever sodium hypochlorite off-gas could be trapped and can result in inaccessibility of components which is a common problem at the GLWA facilities. It is recommended that these points be carefully considered as the details of the piping are determined during design. A standardized pump per mixing zone or a standardized manifold approach is recommended for all GLWA CSO facilities. The final decision between the recommended options for sodium hypochlorite distribution should be determined during design considering the advantages and disadvantages. Two recommended options and piping arrangements are presented in the following paragraphs.

Option 1—Standardized Pump Distribution

This option would consist of utilizing a positive displacement pump for each mixing zone. The recommended type of positive displacement pump for this option is a hose pump (or peristaltic pump for smaller capacities) because of the advantages noted in Section 5.2.2.3. Each pump would require a VFD to adjust the dose in response to varying storm flows and chlorine demands. Each pump would pump to one mixing zone. One spare pump, or more if desired, is recommended with a tie-in to each primary pump to provide redundancy to each mixing zone without significantly increasing the complexity of the piping. The proposed configuration is illustrated in Figure 5-1.

Flow to each mixing zone would be split between mixers using back pressure valves. New back pressure valves are recommended to split the flow between injection points (e.g., mixers and or diffusers). A setting of 15 pounds per square inch gauge (psig) is recommended by Evoqua for Water Champ induction mixers. A pressure tap is recommended upstream of each back pressure valve to allow a calibrated pressure gauge to be moved between these taps to allow verification that each back pressure valve is set equally and to adjust the back pressure valve setting if not. A flow meter is also recommended to further verify equal flow splitting and to allow calculation of total flow rate to that mixing zone. Minimization of mixers and feed points is recommended as discussed herein to reduce the number of flow splits with back pressure valves, flow meters, and pressure gauge taps.

Figure 5-1. Standardized Pump Distribution

The advantages and disadvantages of this option are as follows:

Advantages:

- Simple and reliable control strategy with linear relationship between the pump speed and pump output (not reliant on flow meters due to the predictable speed vs. output relationship).
- Proven common approach for chemical dosing that will meet the permit requirements at each facility.
- Higher turndown ability than manifold option. Turndown ability is based on pump capabilities and not limited by instrumentation.
- If automated mode is not functional then manual mode would consist of manual pump speed adjustment for each pump in response to changing storm flow and TRC measurement.

Disadvantages:

- Higher number of pumps
 - Higher capital cost
 - Greater floor space required
 - More maintenance because pumps are higher maintenance than actuators in the manifold option
 - More equipment that could fail
 - More operations of equipment

Option 2 - Standardized Manifold Distribution

This option would be expected to allow a reduced number of pumps at facilities with a large number of mixing zones and would consist of the following: One or more pumps would pump to a manifold. Each pump would be controlled by a VFD. The pumps could be magnetic drive centrifugal or hose pumps. There would be one branch from the manifold for each mixing zone plus a spare connected to each to provide the same redundancy as the spare pump in Option 1. Every mixing zone would have its own flow meter and flow control valve. There would be a modulating pressure control valve on a recycle loop downstream of the manifold that is controlled to a pressure setpoint to ensure sufficient pressure to split flow in the manifold. The pumping rate is set sufficiently in excess of the desired sum of the feed rates to all feed points. Flow in excess of that distributed through the manifold is recycled to the feed pump suction header. The proposed configuration is illustrated in Figure 5-2.

Standard Manifold Distribution

Figure 5-2. Standardized Manifold Distribution

Flow to each mixing zone would be split the same as Option 1, except given there will be a magnetic meter to each mixing zone the flow meters to each mixer or diffuser need not be sophisticated nor connected to SCADA. Therefore, a rudimentary visual flow indicator is recommended upstream of each back pressure valve. The flow indicators will allow a visual confirmation that hypochlorite is being provided to each location and an indication of equal flow splitting. Minimization of mixers and feed points is recommended as discussed herein to reduce the number of flow splits with back pressure valves, flow meters, and pressure gauge taps.

The advantages and disadvantages of this option are as follows:

Advantages:

- Minimizes number of pumps
- Proven approach to flow splitting.
 - Similar design by author has been in operation since the early 1990s at a WRRF.
 - There are many large WRRFs using a large number of flow control valve (FCV)/flow meter combinations to split air between aeration grids and multiple parallel aeration basins based on dissolved oxygen monitoring.
- A low number of pumps, and a flow control valve and flow meter combination per mixing zone, typically will have a lower capital and maintenance cost than a dedicated pump per mixing zone.
- Similar redundancy to a spare pump can be achieved with a spare branch from the manifold that ties into the discharge to each mixing zone from the manifold.

Disadvantages:

- Will require utilization of the number of mixing zones to match the storm flows. For example, a small storm event needs to be contained in one mixing zone while the peak storm event can utilize all mixing zones. This will ease the turndown requirements of the control instrumentation and the overall system.
- Lower turndown than possible with a dedicated peristaltic/hose pump approach. Minimum turndown of at least 16:1 and possibly as high as 26:1 per mixing zone.
 - The estimated maximum achievable turndown is based on a maximum allowable velocity of 8 ft/sec through a pipe and magnetic meter. Above this, noise and potential for cavitation in the flow control valve can become problematic.
 - The estimated maximum achievable turndown is based on a minimum velocity of 0.3 to 0.5 ft/sec. Below this, flow measurement can drop off to zero in magnetic meters and thus not be reliable.
 - Accommodating the required turndown from the infrequent design peak storm capacity to the more typical storm events could be problematic. The acceptability of the maximum achievable turndowns with this approach should be compared to ratios of peak design storm capacity to historical flows for each facility considering this approach.
- Must properly tune actuators at startup for steady valve operation.
- Even with well-tuned actuators, the valves must adjust frequently during a storm event to rapidly changing flows and chlorine demands, and to the influence of adjacent valves that are changing position.
- The pipe sizes required will result in small valves with large and heavy actuators that must be independently supported (i.e., pipe supports for the actuators).
- Must maintain multiple modulating actuators.
- If automated mode is not functional then manual mode would consist of manually adjusting the position of each of the flow control valves in response to changing storm flow and chlorine residual measurement, verifying adequacy and changing as necessary the pumping rate (but fewer pumps than the dedicated pump per mixing zone option), and verifying adequacy and changing as necessary the pressure control valve position to maintain sufficient pressure in the distribution manifold.

- Failure of the pressure control valve actuator would require manual valve adjustment that must be monitored and adjusted as necessary as the storm flow varies.
- Although not a high likelihood of failure, there is more length of common header piping than the dedicated pump option. This is because the hypochlorite is in a common header not only to the pumps but from the pumps to the manifold and on the return loop downstream of the pressure control valve. This common header length can be minimized by locating the manifold in the pump room. A failure in a common header would disrupt disinfection everywhere.

5.2.2.5 Pump Sizing for Capital Budgeting

As discussed herein, the original facility's design peak flow, an assumed dose of 20 mg/L chlorine for all but St. Aubin, and an assumed minimum sodium hypochlorite solution strength of 5 percent was assumed to size chemical feed pumps at each facility for soliciting budgetary pricing from the leading manufacturer of hose pumps for the two recommended options for feed distribution, as shown in Table 5-4 and Table 5-5.

Table 5-4. Option 1 – Pump Sizing for Standardized Pump Distribution

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Number of Prechlorination Pumps	0	0	0	0	1	0	2	1
Size of Each Prechlorination Pumps (gpm)	N/A	N/A	N/A	N/A	100	N/A	24	30
Number of Mixing Zone Pumps (includes one spare)	9	3	11	5	5	9	3	3
Size of Each Mixing Zone Pumps (gpm)	95	2	197	70	58	31	24	23

Table 5-5. Option 2- Pump Sizing for Standardized Manifold Distribution Using Hose Pumps

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Total Number of Pumps (includes one spare)	4	2	8	3	3	3	2	2
Size of Pumps (gpm)	253	5	282	164	115	124	48	47

The lack of turndown and resulting higher number of required pumps prevents the magnetic drive centrifugal pumps from being a recommended type of pump for Option 1. However, magnetic drive centrifugal pumps are a viable alternative for Option 2. Larger magnetic drive centrifugal pumps are available than with hose pumps. Therefore, budgetary pricing with fewer larger magnetic drive centrifugal pumps was solicited for Option 2 as shown in Table 5-6.

Table 5-6. Option 2- Pump Sizing for Standardized Manifold Distribution Using Magnetic Drive Centrifugal Pumps

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Total Number of Pumps (includes one spare)	3	2	6	2	2	2	2	2
Size of Pumps (gpm)	378	5	394	326	230	246	47	46

5.2.2.6 Chemical Feed System Alternative Costs for Identified Alternatives

The capital costs for the identified chemical feed system alternatives, including the replace in-kind alternative, are summarized in Table 5-7. Detailed cost estimates for each facility are provided in Volume 6 – Appendices, Appendix C under each facility.

Table 5-7. Capital Costs for the Pump Distribution and Pump Type Options

Identified Alternatives	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Facility	Replace In-Kind	Standardized Pump Distribution (Option 1) with Hose Pumps	Standardized Manifold Distribution (Option 2) with Magnetic Drive Centrifugal Pumps	Standardized Manifold Distribution (Option 2) with Hose Pumps
Baby Creek	\$1,657,000	\$3,325,000	\$1,237,000	\$2,388,000
Belle Isle	\$235,000	\$382,000	\$274,000	\$264,000
Conner Creek	\$2,919,000	\$5,409,000	\$2,300,000	\$4,369,000
Hubbell-Southfield	\$970,000	\$1,130,000	\$534,000	\$843,000
Leib	\$1,262,000	\$1,724,000	\$901,000	\$1,178,000
Oakwood	\$1,964,000	\$1,332,000	\$443,000	\$886,000
Puritan-Fenkell	\$340,000	\$687,000	\$383,000	\$545,000
Seven Mile	Not evaluated since facility will be converted to a Capture-Only			
St. Aubin	Evaluated under Sodium Hypochlorite Feed and Storage System Improvements. See Section 14.2.2.2.			
Total Capital Costs for All Facilities	\$9,348,000	\$13,989,000	\$6,072,000	\$10,473,000

It should be noted that Alternative 4 is not further included in the evaluation as it is nearly double the cost of Alternate 3 with no additional benefits or performance enhancements.

The following additional improvements to the sizing of the disinfection systems should be addressed for either Alternative 2 or 3, but are especially important if implementing the manifold alternative due to the lower turndown:

- Refine the maximum design flow once sufficient influent flow data is available from improved influent flow monitoring. While 10 years of reliable historical data will not be available in time for replacing the chemical feed systems, reliable influent flow data in conjunction with precipitation data should be used to better calibrate the collection system model. The model can then be used to determine an appropriate design flow once the model accurately predicts flow to a facility for a given precipitation event.
- Consider a lower design dose at peak flow. Monitoring influent bacterial counts versus flow and evaluating the probability of the peak dose being required concurrent with peak flow could further reduce the required pump sizing. A lower dose may be required at the design peak flow if bacterial counts decrease due to dilution with increasing flow. For example, if the required dose at the design peak flow was determined to be only 10 mg/L rather than 20 mg/L, this would allow the hypochlorite pump sizing to be half that assumed. This in turn would allow dosing at a much lower rate during small wet weather events and thereby help address the turndown limitation of the manifold compared to the pump distribution alternative.

5.2.3 Flow-Paced and TRC-Paced Automatic Chemical Feed

5.2.3.1 Introduction

Based on GLWA personnel input and observations during the site visits, the chemical feed systems do not operate in automatic as intended at any of the facilities. GLWA desires a simple, automated chemical feed system that will improve GLWA's ability to meet both fecal coliform criteria and TRC goals. Manual control is undesirable for the following reasons:

- Operation in manual requires frequent manual adjustments in response to varying storm flow.
- Operation in manual requires frequent sampling and analysis of TRC which is time consuming. This reduces available time for monitoring the facility and attending to other O&M needs.
- Except for extreme storm events at the facilities designed for 5 to 10 minutes contact time, the effluent sample points represent too long of a time delay between the hypochlorite dosing point and measuring point. Thus, adjustments in response to the TRC sampling and analyses at the effluent permit compliance point inherently results in poor control.

The considerations for automating chemical feed pacing are presented here and referenced in the facility-by-facility section because this section applies to most facilities.

5.2.3.2 Automated Sodium Hypochlorite Feed Approach

Consistent dosing in response to rapid changes in flow requires flow pacing, and refinement of the dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The control strategy would be as follows: The operator inputs a starting chlorine dose in terms of mg/L as Cl_2 . The chemical feed rate to that mixing zone would be controlled automatically to achieve that dose based on total facility flow and number of mixing zones in service. Flow splitting between mixers and or diffusers in a given mixing zone would be by non-automated means as described in Section 5.2.2.4 and thus would not be included in the control loop.

The operator will also input a target TRC. A new TRC analyzer sampling slightly downstream of the dose point (e.g., a certain number of minutes downstream at average flow) will be required for this control. The TRC setpoint would be what is desired after complete mixing and the initial rapid chlorine demand. If the measured TRC is less than the setpoint, then the operator entered target dose, still controlled by flow, would be automatically increased to eliminate the difference between the measured TRC and setpoint TRC (i.e., the primary control parameter will be flow pacing to maintain a target dose and the TRC analyzer will be used to adjust the target dose to account for CSO variability). Operator adjustable time delays would also be provided to allow for the adjusted dose to reach the TRC probe before the measurement is used to make the next adjustment to the dose. This approach is anticipated to control both effluent coliform and effluent TRC to a tighter range than possible based on the current manual approach to chemical dosing.

A second TRC analyzer is recommended at each CSO facility for the final discharge point. This will facilitate tweaking the setpoint for the upstream TRC analyzer discussed above and thereby improve compliance with the TRC goal at the discharge. The effluent TRC analyzer results can either be manually considered in tweaking the upstream TRC set point, or if GLWA prefers, it could be used automatically to adjust the upstream TRC setpoint. For example, if it is desired to target a 1 mg/L effluent TRC and the measured effluent TRC is 2 mg/L, and the upstream TRC setpoint was 5 mg/L, the upstream TRC setpoint could be automatically decreased by this 1 mg/L differential to 4 mg/L. And if the measured effluent TRC is 0 mg/L

the upstream TRC setpoint could be increased in increments (e.g., 0.5 or 1 mg/L) with adequate time delays between adjustments, until the effluent TRC reaches 1 mg/L.

Having online TRC analyzers will not only allow effluent coliform and effluent TRC to be controlled to a tighter range than is possible through manual measurements and feed rate adjustments but it will also free up time spent chemically analyzing TRC during a storm so that operators are able to spend their time attending to other needs and monitoring the facility.

Automated control systems require that the flow measurement and TRC analyzers be well maintained and calibrated. With eight active (i.e., excluding Seven Mile) CSO facilities and the recommendation for two TRC analyzers per facility, it is recommended that a single entity, whether internal or contracted, be responsible for maintaining the TRC analyzers to ensure these instruments are operating properly.

Operator training will be critical for successful transition to automated dosing. It is important that the training convey, and operators implement the following:

- The concept of dose being in terms of a concentration (i.e., mg/L) because of the correlation between dose and residual chlorine.
- Regular measurement and entry of sodium hypochlorite strength into the control system. This is important because twice the feed rate is required for the same TRC if the sodium hypochlorite has degraded from 10 percent to 5 percent. The degradation of sodium hypochlorite is unique compared to most other chemicals used in wastewater treatment.

Good operator training will also facilitate operation in manual mode should the TRC analyzer and or flow measurement be out of service. If the TRC analyzer is out of service, the automation system should be designed to allow the flow pacing control to continue. Manual adjustments of the dose should primarily be based on sampling at the upstream TRC sample point with the effluent TRC sample point being a secondary consideration due to the time delay issue discussed above.

5.2.3.3 Review of TRC Analyzer Manufacturers

There are multiple manufacturers with successfully operating TRC analyzers in wastewater applications. The primary types are colorimetric and amperometric. Some require reagents and some are reagent-less. The decision of which analyzer to choose should be based on consideration of some of the attributes of one analyzer versus another and discussions with personnel at other WRRFs or CSO facilities regarding their satisfaction with the equipment. The following are examples of manufacturers that GLWA may want to consider:

- Swan
- Evoqua Wallace & Tiernan
- Chemsan
- Hach
- Rosemount

GLWA may wish to pilot several to identify a preferred analyzer. Once an analyzer is proven at one facility, it is recommended that all the facilities standardize on this TRC analyzer to simplify calibration and maintenance, and to facilitate operators rotating between CSO facilities.

5.2.3.4 Identified Alternatives

Based on the discussion above, the identified alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

5.2.4 Reduce Cost Associated with Large Quantity of Chemical Induction Mixers

5.2.4.1 Introduction

Based on GLWA personnel input and observations during the site visits, reducing the quantity of induction mixers, especially at the facilities with a large number of induction mixers, is desired for the following reasons:

- The mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance
 - Manufacturer maintenance costs are higher than equipment that can be maintained in house
 - Shipping adds costs
 - Turnaround of the Evoqua induction mixers utilized at the majority of GLWA's CSO facilities takes months before the mixer is returned to service.
- Splitting chemical feed to multiple mixers complicates the chemical feed system (e.g., additional back pressure valves, flow metering, pressure monitoring, and piping)

For these reasons, a mixer evaluation was conducted under CS-299 that is applicable to multiple facilities. The importance is greatest at the facilities with the most mixers as follows:

- Conner Creek: 60 induction mixers
- Baby Creek: 32 induction mixers
- Leib: 18 induction mixers

The next largest number of mixers is St. Aubin with seven induction mixers. After that there are only two to four induction mixers per facility and thus the number of mixers at these facilities is not as significant.

The recommendations for facilities requiring a mixer evaluation are presented here and referenced in the facility-by-facility section because this section applies to multiple facilities.

The following alternatives for reducing costs of mixers at Conner Creek, Baby Creek and Leib are provided in the following list and described in the following sections:

- 1) Use an equivalent, less costly induction mixer (potentially Gas Mastrrr induction mixers) for all facilities
- 2) Reduce quantity of induction mixers
- 3) Use a different type of mixer (i.e., vertical shaft)

5.2.4.2 Comparison of Water Champ and Gas Mastrrr Induction Mixers

There are two manufacturers of induction mixers at the CSO facilities, Evoqua Water Champs and Mastrrr Company Gas Mastrrr induction mixers. There are 123 Water Champs at six CSO facilities compared to

only four Gas Mastrrr mixers at two CSO facilities, therefore the majority of GLWA's experience is with Water Champs. The Water Champs have had a higher purchase price, and it is desired to determine if the two manufacturers can be competitively bid when replacing mixers. Therefore, it was requested that the mixing intensity, as defined by the G-value, be compared for the Gas Mastrrr units versus the Water Champs for a given horsepower (hp) unit.

G-Value: Information was gathered on the cone of influence and corresponding mixing energy (referred to as "G-value") for both manufacturers and it was confirmed that Gas Mastrrr induction mixers provide similar G values to Water Champs for a given hp model.

Modifications for Installation of Gas Mastrrr Mixers: The local Gas Mastrrr representative visited a couple of the GLWA facilities where Water Champs are used and concluded the guide rails and controls would be reusable but new attachment brackets may be required.

Comparison of Maintenance Work Order History: Currently, GLWA has Gas Mastrrr induction mixers at Hubbell-Southfield (3) and Seven Mile (1). However, given the hydraulic issues limiting discharge from Seven Mile, the three Gas Mastrrr induction mixers at Hubbell-Southfield are the primary basis for forming opinions on relative reliability. For comparison there are a combined 123 Water Champ induction mixers at six of the CSO facilities. An evaluation of the number of maintenance work orders for the chemical induction mixers over the past five years is presented in Table 5-8 (as presented in the Maintenance Work Order Review for Facilities Assessment Task report). Although there is a large majority of Water Champ mixers, the annual average number of work orders per mixer is similar.

Table 5-8. Review of Chemical Induction Mixer Work Orders by CSO Facility

CSO Facility	Mixer Manufacturer and Model	Number of Installed Mixers	Total Number of WOs for Chemical Induction Mixers	Average Number of WOs per Mixer Over a 5-Year Period
Baby Creek	Evoqua (Water Champ)	32	38	1.2
Belle Isle	Evoqua (Water Champ)	4	0	0
Conner Creek	Evoqua (Water Champ)	60	51	0.9
Hubbell Southfield	Gas Mastrrr	3	5	1.7
Leib	Evoqua (Water Champ)	18	41	2.2
Puritan-Fenkell	Evoqua (Water Champ)	2	0	0
Seven Mile	Gas Mastrrr	1	0	0
St. Aubin	Evoqua (Water Champ)	7	15	2.1
Total		127	150	1.2

Repair Center: Another consideration for the mixers is the location of the repair center and the associated shipping costs. Gas Mastrrr indicated a local repair shop in Detroit area would be used, whereas Evoqua's repair center was historically located in Louisiana. As of late 2020, however, a repair facility is reportedly located in Belleville, Michigan.

Cost Comparison: Pricing was received from both manufacturers that varied with the number of units purchased, whether existing units were exchanged, and with and without explosion-proof motors. Table 5-9 provides a cost comparison of the two sizes for which explosion-proof motors were quoted by both manufacturers, assuming no existing units are exchanged, and using their bulk pricing discount assuming ten mixers are purchased at a time. The Gas Mastrrr mixers were quoted at 70 percent to 72 percent of the

Water Champ mixers. It is possible that Evoqua will improve their Water Champ pricing in a true competitive bid situation.

Table 5-9. Cost Comparison Between Water Champ and Gas Mastrrr Induction Mixers

Motor hp	Water Champ (\$/mixer)	Gas Mastrrr (\$/mixer)
15	\$37,000	\$26,300
20	\$40,000	\$29,300

Based on the G factor, the apparent interchangeable use of the existing guiderails and controls, work order history on reliability, and a comparison of quotes, GLWA can competitively bid Gas Mastrrr mixers and Water Champ mixers when replacing mixers going forward. The attachment brackets, and any other appurtenances as required to utilize the alternative manufacturer at a given location, can be specified to be included in the bid by that company to ensure all cost for switching to an alternative manufacturer are accounted for.

5.2.4.3 Reduce Quantity of Existing Mixers

This section evaluates the feasibility of reducing the number of mixers at each facility, now that many years of various storm events and operating experience has been obtained.

To understand the basis for the current number of mixers at each facility, it is helpful to review design documents. The basis of design for Conner Creek states:

"The number and size of the mixers was based on data collected during a mixing test conducted by Alden Research Laboratory, Inc in July 1999. The purpose of the test was to define the volume of water affected by the mixer at the design flow...

Mixing effectiveness was determined by measuring the concentration of a fluorescent tracer at two vertical planes, 10 feet (ft) and 58 ft downstream from the impeller of the mixers. The velocity and tracer concentration data were normalized by dividing the measured values by the theoretical average value. The theoretical channel velocity was 3 fps...

At the 10-ft vertical plane, a "uniform mix" was observed to occur within a cross-sectional area of approximately 24 square ft, which was equivalent to 33% of the total cross-sectional area. At the 58-ft vertical plane, the fluorescent tracer dye was observed throughout the 10-ft x 8.5-ft cross sectional flow path. Additionally, at the 58-ft vertical plane, there was an obvious gradation of tracer concentration, the highest concentration being at the water surface. The cross-sectional area of the test channel was approximately 1/6 of the full-scale channel, therefore, it is recommended to equip each of the screening/mixing channels with six, 20-hp induction-type mixers."

In summary, the mixer achieved non-uniform tracer dispersion across the entire cross-sectional area of the test channel at 58 ft and uniform dispersion across 33 percent of the cross-sectional area at 10 ft, the only two vertical planes tested. The basis, and significance if any, of the 58 ft vertical plane sampled is not explained. If one were to extrapolate the dispersion being across 33 percent of the cross-sectional area at 10 ft, then it is possible that dispersion occurred across the whole cross-sectional area at 30 ft. It is not apparent from the basis of design report that interpretation of the dispersion results was used in choosing the number of mixers for full-scale design. Instead, it appears that the determination of how many mixers to incorporate into the full-scale design at Conner Creek was simply a multiplication of the test channel cross-sectional area to the full-scale facility cross-sectional area. This raises the question that if they had instead chosen a pilot facility that was 1/4th the size of the full-scale facility, would they have designed four mixers rather than six mixers per mixing zone?

Computational Fluid Dynamics (CFD) is a powerful hydraulic analysis and design tool that was not available when the CSO facilities were designed. A primary issue with the physical model approach previously taken is how to interpret and apply the test results to design. With CFD modeling, the dispersion of chemical can be determined with relatively high certainty for any given number of mixers and mixer locations. Thus, the required number of mixers can be determined. A required input of CFD modeling is the mixing characteristics of each mixer to be modeled. Therefore, this information would be required from the mixer manufacturers.

CFD modeling is recommended for Baby Creek, Conner, Creek, and Leib, and if desired St. Aubin as well although only a two-mixer reduction would be anticipated there. The small number of mixers at the remaining facilities minimizes potential mixer reductions at those facilities, especially considering the benefit of some redundancy should a mixer become non-operational and not be available during a CSO event. For example, at a facility with only two, three, and four mixers, one mixer out of service represents a 50 percent, 33 percent, and 25 percent reduction in overall facility mixing capacity, respectively. The implications of one or two mixers being out of service at the three facilities with the largest number of mixers are much smaller.

Consultation with the CFD modeler should occur during scoping of the CFD modeling project to decide on the best modeling approach. It should also be determined whether the peak design capacity of the facility is the only condition to be modeled or whether any lower flow rates should also be modeled. The following is a preliminary list for consideration:

- Modeling of the existing number and size of mixers to develop a baseline.
- Modeling with fewer of the existing mixers in existing locations to determine what mixers if any could be eliminated.
- Modeling with fewer of the existing mixers but in optimized locations. Utilization of existing floor openings should be given first preference. If significant benefits are anticipated with alternative mixer locations then interferences and cost implications of a new floor penetration, hatch, and mixer removal infrastructure should be considered when selecting alternative locations to model.
- Modeling of larger (e.g., higher hp) induction mixers. This could be done in conjunction with one or both of the previous two bullets.

Although not recommended because it would rely more on trial and error and extensive sampling, an alternative to CFD modeling would be to remove mixers in one mixing zone and sample at enough points at the discharge end of the mixing zone to analyze the adequacy of chlorine dispersion. This could be accomplished by installing submersible sample pumps or sample pipes connected to self-priming sample pumps located on the operating level. A significant number of sample pumps or sample pipes would be required to adequately cover the cross section leaving the mixing zone. Initial testing could be conducted with the currently installed number of mixers to develop a baseline. Then testing could be conducted with one or more mixers removed. The intermittent and highly variable nature of CSOs make full-scale testing much more challenging than would be the case at a continuously operating wastewater treatment plant. Drawbacks of this approach compared to CFD modeling include:

- The design capacity of the facilities corresponds to a very infrequent event with a flow far in excess of typical peak storms. Therefore, testing at lower flows is unlikely to be fully indicative of the adequacy of mixing at peak design flow.
- The optimum positioning of mixers would be by trial and error and would be limited to positions on existing rails.
- Testing of each configuration would likely need to occur during multiple events, with an emphasis on capturing data during large events. This could require testing in one configuration (e.g., number of

mixers and mixer positioning) for a year or more depending on how soon a peak event occurs after setting a given configuration.

- The lack of access favors installing a matrix of sample points to provide adequate sampling. The associated piping would likely accumulate debris passing through screening and require periodic cleaning.

Without CFD modeling there is not a real basis for estimating whether the number of mixers can be reduced and by how much. Therefore, assumptions are required for estimating the costs of this alternative. Table 5-10 summarizes the assumptions for cost estimating this alternative.

Table 5-10. Reduced Number of Induction Mixers Alternative Summary

Facility	No. of Mixing Channels	Existing Number of Mixers Per Mixing Zone	Existing Total Number of Mixers	Assumed Number of Mixers Per Mixing Zone	Assumed Total Number of Mixers	Cost Per Mixer ^a	Cost Savings per Facility Using Reduced No. of Mixers
Baby Creek	8	4	32	2	16	\$50,000	\$800,000
Conner Creek	10	6	60	4	40	\$50,000	\$1,000,000
Leib	4	4	16 ^b	2	8 ^b	\$50,000	\$400,000

^a Based on existing Water Champ induction mixers with explosion-proof motors (Table 5-9), with a contingency and installation cost.

^b The two prechlorination mixers are not included in this evaluation and would remain.

5.2.4.4 Alternative Mixer Technology – Vertical Shaft Mixer

Vertical shaft mixers are a more common type of mechanical mixer at wastewater and water treatment plants than induction mixers. Vertical shaft mixers are typically very low maintenance and highly reliable. Figure 5-3 shows a vertical shaft mixer potentially applicable to Conner Creek.

Figure 5-3. Vertical Shaft Mixer

The primary concern with this proven mixing technology if applied to a CSO facility is the potential for ragging and questions regarding whether that would cause damage to the mixer or result in significantly greater maintenance. Maintenance on vertical shaft mixers for this application would consist of:

- Change oil every 6 months to a year (potentially less frequent if the oil is sampled and analyzed).
- Grease bearings at the same time as oil changes. There is an upper and a lower bearing in the gearbox.
- Removal of rags from the shaft and impellers periodically. The amount of ragging will vary with CSO facility due to differences in screen openings and the quantity of screenings present in the CSO.
- Service the steady bearing every two years. This is a floor mounted bearing. Steady bearings are custom made for the application and their design will vary. An example of steady bearing is shown in Figure 5-4. Given the presence of solids, this application may involve a water flush to the lower bearing similar to pump seal water in order to maximize bearing life.

For the Leib facility, the belowground location of the mixer chamber and limited headspace would require significant structural modifications above the mixing chambers to allow the vertical shaft mixer to be installed and removed. Based on these constraints, the vertical shaft mixer is not further considered at the Leib facility and only induction mixer alternatives will be considered at Leib.

In addition to vertical shaft mixers typically being very low maintenance and highly reliable, another advantage of vertical shaft mixers over submersible mixers are the first two maintenance tasks noted above are on components located on the operations floor.

Drawings, facility design flows, and other relevant information were provided to Philadelphia Mixing Solutions and recommendations and budgetary pricing requested for the three facilities with the largest number of induction mixers. The three facilities were Conner Creek, Baby Creek, and Leib. The next largest number of mixers is St. Aubin with seven induction mixers. If successfully implemented at the facilities with the largest number of induction mixers, then replacement of six induction mixers with vertical shaft mixers downstream of screening could be considered at St. Aubin in the future. The seventh induction mixer at St. Aubin is a prechlorination mixer upstream of screening and would be assumed to remain. There are only one to four induction mixers per facility at the remaining facilities with induction mixers and thus the number of mixers at these facilities is not significant enough to warrant replacement with vertical shaft mixers.

- Philadelphia Mixing Solutions selected mixer sizes to rapid mix sodium hypochlorite based on the mixing zone size and configuration and the design peak flow of the facility. The proposed vertical shaft motor hp per mixing zone exceeds that of the existing induction mixers. The fact that the energy demand is concentrated in fewer larger motors will require changes to the power distribution thereby affecting capital cost. However, the intermittent nature of the CSO facilities is expected to minimize the life-cycle energy cost differences between the two technologies. Two features were proposed by Philadelphia Mixing Solutions to address the concerns about ragging:
 - 1) Steady bearing. This is provided to prevent shaft deflection from rag accumulation on the shaft and impeller and resulting stress on the upper bearings.
 - 2) Curved-blade turbine impeller intended to minimize ragging. The impeller is illustrated in Figure 5-5.

Figure 5-5. Curved-blade Turbine Impeller

- The mixers are designed to run during fill/drain operations, i.e., as the water level rises, or drops back down, through the level of the impeller(s). Although the mixer could run dry for short periods of time, the manufacturer does not recommend running them dry for any extended period of the time because

if solids are present in the steady bearing, the wear sleeve could be damaged. The mixers at Conner Creek and Baby Creek would have three impellers per shaft to provide rapid mixing at multiple depths. The mixers could run with any combination of impellers being above or below the water level due to water level variation during an event. Two mixers were proposed at each existing mixing zone for all three facilities. Table 5-11 summarizes the vertical shaft mixer concept for the two feasible facilities.

Table 5-11. Vertical Shaft Mixer Alternative

Facility	No. of Mixing Channels	Mixers Proposed Per Channel	Total Mixers Required	Cost Per Mixer	Mixer Equipment Cost Per Facility	Per Mixer Motor hp	Total Mixer Motor hp
Baby Creek	8	2	16	\$70,000	\$1,122,000	50	800
Conner Creek	10	2	20	\$79,000	\$1,578,000	75	1,500

- This alternative would cut the number of mixers from 60 to 20 at Conner Creek and from 32 to 16 at Baby Creek. Vertical baffling was recommended by the mixer manufacturer at each mixer location to facilitate turbulence rather than bulk laminar liquid rotation. Mixer locations (red) and proposed baffles (green) for each facility are illustrated in Figure 5-6, Figure 5-7 and Figure 5-8.

Figure 5-6. Vertical Shaft Mixers (Profile) Conceptual Implementation - Conner Creek

Figure 5-7. Vertical Shaft Mixers (Plan) Conceptual Implementation - Baby Creek

Figure 5-8. Vertical Shaft Mixers (Plan) Conceptual Implementation – Leib (Shown for reference only)

The in-series orientation at Conner Creek and Baby Creek would have the added advantage of providing partial redundancy because rapid mixing, at half the normal energy input, would continue to occur if there was a problem preventing operation of one mixer in that pair.

The advantages and disadvantages of the vertical shaft mixer is as follows:

Advantages:

- Typically very low maintenance
- Typically highly reliable
- Components requiring routine maintenance are located on the operations floor
- Cuts the number of mixers from 60 to 20 at Conner Creek and from 32 to 16 at Baby Creek
- Motor and gear drive are serviceable thereby minimizing the need to ship components to the manufacturer's maintenance facility
- Mixer can be run over the range of water levels during an event. This compares to the need to start and stop induction mixers installed at different elevations depending on water level.
- The in-series orientation at Conner Creek and Baby Creek would provide partial redundancy if one mixer were out of service (i.e., 50 percent mixing intensity)

Disadvantages:

- Requires steady bearing on the floor of the mixing zone due to the application. This is less typical for vertical shaft mixers and the associated maintenance requirements are site-specific and difficult to predict. Maintenance on these requires
- Steady bearing may require seal water to flush debris which could shorten the life of the bearing.
- Requires periodic removal of rags and debris from the shaft and impeller. CSO is not a typical application for vertical shaft mixers and the associated maintenance requirements are site-specific and difficult to predict.

- Requires some baffling additions. The head loss associated with these is anticipated to be insignificant but this should be verified during design.
- Higher total hp than the existing induction mixers. However, the intermittent nature of the CSO facilities is expected to minimize the life-cycle energy cost differences between the two technologies.

5.2.4.5 Alternative Evaluation

The 20-year life-cycle costs are presented in the alternatives evaluations contained in the Disinfection sections of the Baby Creek (Section 6.2.2) and Conner Creek (Section 8.2.2). These are the only two facilities where the vertical shaft mixer is considered feasible. The alternatives evaluation also includes the anticipated annual maintenance costs associated with each mixer.

It is recommended that CFD modeling be conducted as described herein to determine by how much the number of induction mixers can be reduced.

5.2.5 Total Chlorine Residual Reduction

TRC reduction (i.e., dechlorination) is currently not required for CSO discharges at any of the existing CSO facilities. However, the WWMP evaluated the size and location of dechlorination facilities in the section on potential future regulations. The capital cost estimates from the WWMP are presented in Table 5-12. GLWA does not anticipate a TRC requirement in the next 20 years while the Long Term CSO Control Plan is being executed because of finite resources to support other capital expenditures.

Table 5-12. TRC Reduction Capital Cost Estimates From the WWMP

CSO Facility	Estimated Capital Cost ^a (ENR CCI 11500 2019)
Baby Creek SDF	\$ 22.5 million
Conner Creek RTB	\$ 46.2 million
Hubbell Southfield RTB	\$ 16.5 million
Leib SDF	\$ 10.8 million
Puritan-Fenkell RTB	\$ 7.7 million
Oakwood RTB	\$ 10.6 million
Puritan-Fenkell RTB	\$ 7.7 million
Seven Mile RTB	\$ 7.3 million
St Aubin SDF	\$ 5.2 million

^a WWMP estimated TRC reduction capital costs, however these capital costs are not anticipated in the 20 year planning period of this report.

5.3 Electrical

5.3.1 CSO-Wide Lighting Replacement Project

A light-emitting diode (LED) Lighting Replacement project, conducted under Job Order Contract (JOC) No. 9, was completed in late 2020. The project consisted of replacing the originally installed fluorescent and sodium vapor light fixtures with new energy-efficient LED lighting fixtures at all CSO facilities. This project included a 7-year warranty on the new fixtures. Because of this recent project, the existing lighting at the facilities was not evaluated under CS-299.

New and additional lighting locations were discussed with O&M staff at each facility where lighting improvements are desired to better perform maintenance and daily operations activities. If applicable, the locations for additional lighting are presented in the Electrical section of each facility.

5.3.2 Power Quality Monitoring

GLWA currently has an ongoing power monitoring project for all CSO facilities. The project consists of installing a Schneider power monitoring system, which will enable GLWA to monitor the power quality of the electrical systems at each facility. The system will detect abnormal conditions, locate circuit insulation faults, and monitor the electrical equipment. It will allow GLWA to efficiently identify and track power event causes, patterns and system capacity to avoid overloads and failures. The power monitoring system has the ability to capture and record power monitoring data which can be used to troubleshoot and address current and future power issues at the facility.

5.4 Instrumentation and Control

5.4.1 Introduction

There are a number of I&C-related common improvements that could be made at the CSO facilities to standardize their operation, reduce maintenance costs and improve operations. The needs are described in this section and referenced, as appropriate, in the facility-by-facility assessments in the following bullets. The common needs include:

- Control System Improvements
- Evaluation of Level Measurement Technology – Ultrasonic vs Radar Instruments
- Chemical Fill Station Level Indicators
- Evaluation of Valve Control Philosophy – Valve Network (PakScan) vs Hardwired
- Fire Alarm System and Gas Monitoring Minimization
- Open Channel Flowmeter Alternatives
- Process Monitoring Cameras
- Additional Local Control
- Generator Run Status Signals to Historian
- Study for Disabled Motor Moisture Detection Capabilities

SCADA Data Review: In order to better understand the condition of level and flow signals generated from the numerous level sensors and flow meters throughout the nine CSO facilities, Jacobs conducted a detailed SCADA Data Review. This evaluation obtained and reviewed SCADA data from a recent 6-month period (August 2019 to February 2020). This evaluation was used to help determine whether some of the redundant instrumentation could be minimized (for example, see I&C sections of Baby Creek and Conner Creek). Furthermore, this evaluation was used to populate information in the CS-299 Condition Assessment related to whether the instrument “Performed Its Intended Function.”

5.4.2 Control System Improvements

Because the CSO facilities were constructed at various times over the last 25 years, the control systems vary. Table 5-13 provides a summary of the existing control systems at each facility. The table also provides the proposed and recommended upgrades for the control systems at all the facilities to standardize the systems and make operating these facilities more similar from one facility to another.

Table 5-13. Existing and Proposed SCADA Control Systems at Each CSO Facility

Facility	Existing Control System (Version)	Proposed and Recommended Upgrades
Baby Creek	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7 Replace local control panel at Sampling Building and provide control from Sample Building
Belle Isle	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7 Add root switch for network redundancy
Conner Creek	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7
Hubbell Southfield	Rockwell ControlLogix PLC's with Factory Talk software	Replace entire control system (proposed project under CS-299)
Leib	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project
Oakwood	Emerson Ovation (O.V.3.5.0)	Ovation System Upgrade to O.V.3.7
Puritan-Fenkell	Rockwell PLC 5 with RSView software	Replace entire control system (proposed project under CS-299)
Seven Mile	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project
St. Aubin	Rockwell PLC 5 with RSView software	Upgrade is ongoing through "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project

Note:

PLC = programmable logic controller

During CS-299 Facilities Assessment meetings, GLWA personnel requested that the control systems and screen graphics be standardized across facilities so that staff could more easily understand the controls and operation from one facility to another. GLWA SCADA Governance Standards require that all CSO facilities use Ovation workstations with new high-performance graphics. Version 3.7 of Ovation should be used. The recommendations in the following paragraphs address these issues.

"Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" is a project that is intended to replace the control systems at the three facilities mentioned. The request for proposals (RFP) for this design/build project should be issued within the next few months (as of August 2020). A Jacobs team member was involved in the development of the RFP documents for this project and was able to convey the GLWA CSO team's desire for standardization. For this project, the workstations with high-performance graphics will be Ovation. The RFP will allow for either Ovation or Rockwell control system to be bid, so that it can be more competitively priced.

Replace Entire Control System: Hubbell Southfield and Puritan-Fenkell control systems and workstations are Allen Bradley programmable logic controller (PLC)-based systems that are obsolete and do not meet GLWA's Governance Standards. These systems should be replaced. The Facility assessments for Hubbell Southfield and Puritan-Fenkell provide project descriptions and recommendations for the replacement project.

Ovation Control System Upgrade: The Ovation Control System at the existing four facilities (Baby Creek, Belle Isle, Conner Creek and Oakwood) will provide GLWA reliable operation for many years. With the advances in technology and new operating systems, it is logical to upgrade the Ovation system to take

advantage of new capabilities to improve performance and ensure reliability of the system. For the Ovation system to have high-performance graphics and elements, the system needs to be upgraded to version O.V.3.7. Once upgraded, the system will be able to utilize the latest graphic elements in Ovation that GLWA is currently pursuing.

The potential control system upgrades are listed in the following paragraphs (and are subject to change during design phase):

- High-Performance Graphics: Provide use of new screen graphic macros to maximize the experience with high-performance graphics.
- Remote Node Interface: Ability to expand the system with Ethernet based remote nodes that have the capability to handle smart modules such as ELC, Profibus, or Fieldbus in remote locations.
- Machinery Health monitor: Vibration sensors to collect raw data and software to analyze and predict failures.
- Updated OCR1100 Controller: Updates to controller software and interfaces to handle high speed applications along with an enhanced set of control algorithms.
- Windows Server 2016 and Windows 10: Operating system obsolescence will no longer be an issue along with security patch availability.
- Trusted Domain capabilities: Allow all GLWA system credentials to be available for authentication at all sites and systems.
- HART capabilities enhancements: Allows the system to communicate to 254 HART variables via the wireless HART device.
- Enhance system viewer/analyzer: Provide the ability to troubleshoot by including the option to filter by message type or time. Additionally, the level of criticality can be selected to ensure only the most important items are viewed.
- Gigabit network communication capability and up to 500,000 tags.
- Upgrade Fiber Network to OM3 fiber to support greater distances with gigabit capabilities.

5.4.3 Evaluation of Level Measurement Technology – Ultrasonic vs Radar Instruments

Many different technologies exist for level measurement. The predominant methods for measuring liquid level in the water industry are through ultrasonic level measurement and radar level measurement. Both methods rely on transmitting a wave and tracking the time it takes to receive an echo from the reflected wave. With ultrasonic, the wave is acoustical and with radar, the wave is electromagnetic. When the CSO Facilities were originally designed and constructed, ultrasonic was the dominant technology for level measurement. Radar level instruments were just beginning to come to market and were much more expensive and not as accurate as ultrasonic level instruments. It was common to have the ultrasonic technology be the primary level instrument and the radar technology to be the secondary level instrument.

Today, the opposite is true. Radar level measurement has improved, and for many applications is superior to ultrasonic level measurement. The frequency of the electromagnetic wave has increased with each new version introduced which provides for a narrower beam spread with less chances of error introduced from waves reflecting off of different surfaces. In addition, the higher frequency allows for more accurate level measurement in water containing small particles of debris and/or foam. Radar level instruments are a 2-wire, loop powered device and do not require a separate 120-volt (V) power feed, unlike ultrasonic level instruments. This saves on installation costs by eliminating additional conduit and wire.

In the future, Jacobs recommends that new level instruments would be radar as the primary level and ultrasonic as the secondary (if secondary is required). Since the radar instruments are loop powered, an additional source of 120V power and the associated conduit and wire is not required. The radar level instruments tend to have a lower unit cost and slightly more accurate and reliable than ultrasonic. For existing installations where ultrasonic level instruments are successfully being used and it is time for replacement, the recommendation would be to re-install an ultrasonic level instrument, since 120V power and the associated conduit and wire is already present, and the mounting location is already set for ultrasonic.

5.4.4 Evaluation of Open Channel Flowmeter Technologies

At the CSO Facilities, Accusonic open channel flowmeters are commonly used to measure flow. The meters are expensive to purchase, expensive to maintain, and frequently have issues accurately measuring flow.

Two alternatives are available for flow measurement besides the Accusonic units. The alternatives are described in the following paragraphs.

Alternative 1 - Laser-Doppler Velocity Flow Measurement: The non-contact laser-doppler velocity sensor measures flow by using a combination of a laser beam to measure velocity in a pipe or channel and an ultrasonic level sensor to measure the level of the liquid in the pipe or channel. Once the level of the channel is known, the laser beam is focused on a specific point and the frequency shift is measured on the returned light. The flow is then calculated from the cross-sectional area of the pipe or channel (accounting for level) multiplied by the velocity. An example of this type of flowmeter is the TieNet 360 Laser Flowmeter.

Advantages:

- Non-contact with the liquid in the pipe or channel. This provides for better accuracy by not disturbing the flow of liquid and will also remain cleaner by not being exposed to debris in the liquid.
- Ability to be submerged and still measure flow (requires optional surcharge sensors).
- Less expensive than Accusonic.

Disadvantages:

- The 45-degree angle of the laser beam requires special mounting considerations. This involves using an opening in the pipe or channel to accommodate the geometry of the 45-degree beam along with the downward facing ultrasonic level sensor. An alternative is to use a remote mounted ultrasonic meter and use one opening where the 45-degree beam enters the channel, or use two smaller openings; one above the ultrasonic meter on the main unit, and one for the 45 degree beam.
- Generally, requires a larger structure to account for the special mounting.
- Distance limitations between the flow sensor and flow transmitter. The manufacturer supplied cable is limited to a maximum 150 ft. In order to increase this distance, an additional extender module is required, and larger cables are required to counteract the voltage drop in the cable.

Alternative 2 - Radar Velocity Flow Measurement: Similar to the laser-doppler velocity flowmeter, the non-contact radar velocity sensor measures flow by using a combination of a radar beam to measure velocity and an ultrasonic level sensor to measure the level of the liquid in the pipe or channel. The radar is pointed to the center of the flow stream to measure surface velocity by calculating the frequency shift of the returned radar beam (doppler effect). The flow is then calculated from the cross-sectional area of the pipe or channel (accounting for level) multiplied by the velocity. An example of this type of flowmeter is the Hach Flo-Dar.

Advantages:

- Non-contact with the liquid in the pipe or channel. This provides for better accuracy by not disturbing the flow of liquid and will also remain cleaner by not being exposed to debris in the liquid.
- Ability to be submerged and still measure flow.
- Less expensive than Accusonic.

Disadvantages:

- The mounting design of the radar velocity flow measurement is meant to be installed on a bracket located in the bottom of a manhole directly above the channel or pipe opening. Access to the meter would be limited unless a large manhole was used above the pipe or channel.
- Would require a larger structure similar to the laser-doppler velocity meter to provide access to the meter.

It is recognized that GLWA has recently replaced all of the Accusonic influent flow meters at the large CSO facilities (i.e., Baby Creek, Conner Creek, Hubbell Southfield, Leib and St. Aubin). These facilities have a contract for bi-annual maintenance of these meters. Given this current situation, it is recommended that the Accusonics continue to be used. As these units age and as technology continues to advance, alternative flow meters could be evaluated in the future.

Jacobs recommends one location (Conner Dewatering) where a new Laser-Doppler Velocity Flow Meter should be installed. This is further discussed in Section 8.2.7.3.

5.4.5 Chemical Fill Station Level Indicators

Level sensor indicators are necessary at the fill stations of all chemical storage tanks. This allows contractors to monitor tank level from outside the building while delivering sodium hypochlorite. GLWA staff are replacing level sensor indicators at St. Aubin and Leib, but replacement is required at Belle Isle. All other facilities require installation of new level sensor indicators.

For the CSO Facilities which require new level indication, it is recommended for the design to include a NEMA 4X enclosure, digital process display with large, red characters which are easy to read, panel heater, and an alarm horn or strobe to indicate when the tank is approaching a high level. The 4-20 milliamperes (mA) level signal used for the process display indication should be part of the 4-20 mA instrument loop between the level sensor and PLC analog input and should indicate how full the tank is and how close it is to overflow. The alarm horn or strobe should be powered through a relay from the process display and based on an adjustable setpoint through the process display setup. A reasonable level should be chosen for the setpoint, which might be 12 inches (in.) to 24 in. below the top level of the tank. If a horn is used for the level indication panel, a "test" and "alarm silence" pushbutton should be incorporated to the front of the panel.

5.4.6 Evaluation of Valve Control Philosophy – Valve Network (PakScan) vs Hardwired

The PakScan valve network is a proprietary networking system for use with Rotork electric actuators. The valve network utilizes a serial communication protocol to carry all valve actuator status and control signals over a two-wire system. Valve networks have advantages and disadvantages. For PakScan, the network can accommodate hundreds of individual valve actuators spanning over many miles apart. The valve network is capable of transmitting a multitude of status and control signals nearly instantaneously across the entire network. Some of the disadvantages of the PakScan valve network include losing status and control

of all valve actuators in the event of a cable malfunction and associated networking difficulties during power cycles (such as valve actuators losing IP addresses while the network is coming back online).

For the CSO Facilities which utilize PakScan valve networks (i.e., Baby Creek, Conner Creek, Puritan-Fenkell, and Seven Mile), Jacobs considered an alternative of maintaining the existing valve network for status monitoring, but converting to hardwired control for critical status and control functions. The addition of hardwired control would involve the addition of conduit and wire between the valve actuators and the nearest PLC panel. Any discrete status and control would be through No. 14 AWG wire. Additional I/O would likely be required in the PLC panels. If the PLC panel would not have space or capacity for additional valve actuator I/O, remote I/O panels would be required to collect the status and control signals and be tied into the local PLC panel. The major benefit of this alternative is that, in the event the valve network experiences issues or outages, the hardwired control would still remain as a backup to keep the CSO Facility in operation.

Construction costs (without Contractor overhead and profit or Engineering design) for this concept for all the actuators at the four CSO facilities was found to be fairly expensive, as follows:

- Baby Creek (60 actuators): \$204,000
- Conner Creek (107 actuators): \$355,000
- Puritan Fenkell (19 actuators): 68,000
- Seven Mile (15 actuators): 54,000

Based on this information and discussion with GLWA, the cost/benefit of this alternative was not considered to be favorable. The exception is the 16 effluent relief gates at Conner Creek, which could cause major flooding damage in the collection system if they do not open as programmed during a large storm event. As such, this alternative is not considered further, except for the Conner Creek effluent relief gates.

5.4.7 Fire Alarm System and Gas Monitoring Minimization

Minimization of Fire Alarm Systems: GLWA requested that Jacobs investigate potential locations where fire alarm and sprinkler systems could be eliminated. As part of this investigation, Jacobs recognizes that each facility was designed by professionals to meet current fire and safety requirements and codes. Furthermore, the designs and final installations were reviewed and approved by the City Fire Marshall. For these reasons, we do not recommend that the current fire safety systems be modified, unless further evaluated under a separate study.

Removal of Gas Monitors from Various Basins: GLWA also requested that Jacobs investigate the potential removal of gas monitors in the basins for Belle Isle and Oakwood CSO Facilities. When originally installed, the gas monitoring in the basin was the primary method to determine if dangerous gas levels were present and if it was safe for personnel to enter. Since then, the standard operating procedures have been updated to make personal meters worn by personnel the primary means for checking for dangerous gas levels. Per NFPA 820 Standard for Fire Protection in Wastewater Treatment and Collection Facilities, Table 4.2.2, Row 32, Fire Protection measure, which include combustible gas detection, is not required in wastewater holding basins.

For the gas monitoring equipment in the basins at Belle Isle and Oakwood, the recommendation is to remove the existing gas monitors to avoid the effort required to maintain the sensors. This recommendation is also based on the fact that entry into basin (confined space) requires individuals to have their own gas monitor, along with fans on. The existing conduit and wire should remain as spare and left for future use.

Gas monitors in the Headworks should remain for the same reasons as the fire alarm systems mentioned above.

5.4.8 Process Monitoring Cameras

During Facilities Assessment meetings with O&M staff, GLWA requested that Jacobs evaluate locations in which additional cameras would be beneficial to monitoring operations. With GLWA input, the locations of existing cameras and the number of new cameras required at the CSO facilities were identified. A summary of desired camera locations is presented in Table 5-14. For this report, the costs associated with cameras are included in the individual facility I&C Improvements project.

Table 5-14. Process Monitoring Camera Needs at Each CSO Facility

Facility	Location	Number of new cameras required	Notes
Baby Creek	Headworks	4	One camera for a group of four screens
	Influent Area	1	Focused on area upstream of the weir wall
	Chemical Room	2	PTZ ^a
Belle Isle	Headworks	1	Existing camera in the headworks needs updating
	Chemical Room	1	
Conner Creek	Headworks	3	
	Chemical Room	2	One camera inside and one camera outside. PTZ
	Outfall	0	Camera will be installed as part of ongoing security project
Hubbell-Southfield	Headworks	3	PTZ
	Chemical Room	1	PTZ
	Outfall	1	
Leib	Headworks	0	There is an existing camera in the headworks area
	Chemical Room	1	PTZ
Oakwood	Headworks	3	PTZ
	Chemical Room	2	PTZ
	Pump Room	2	PTZ
Puritan-Fenkell	Headworks	2	
	Chemical Room	1	PTZ
	Outfall	1	PTZ
Seven Mile	Headworks	No	
	Chemical Room	No	
St. Aubin	Headworks	1	Existing camera in headworks area needs updating
	Chemical Room	1	PTZ

^a PTZ is a point, tilt, zoom camera

5.4.9 Install Local Control Near Process Equipment

GLWA staff requested local control capability for some equipment to improve operability, for example submersible dewatering pumps and mixers at some locations. For areas where local control would provide a benefit, a standard approach would be taken for all CSO Facilities.

- In classified areas, local control stations should be added next to the equipment in NEMA 7 explosion-proof enclosures. Start and stop pushbuttons, local-off-remote selector switches and push-to-test indicating lights would be specified for the local control station. For applications involving VFDs, speed indication and speed control potentiometers should be included on the local control station.
- For non-classified areas, local control stations should be added next to the equipment in NEMA 4X stainless steel enclosures. Start and stop pushbuttons, local-off-remote selector switches and push-to-test indicating lights would be specified for the local control station. For applications involving VFDs, speed indication and speed control potentiometers should be included on the local control station.

The local control stations would require new conduit and wire back to the motor starters, typically located within MCC. The internal control circuits would need to be modified and updated to include the additional local control stations.

For typical applications, the multi-conductor exposed cables would route up through the wet-well to either quick-disconnect devices, or permanent terminal boxes. Seal-off fittings would be incorporated where required by code between the local control stations and terminal boxes/quick-disconnect devices.

The Instrumentation and Control sections of each facility provide the locations where remote control of equipment was recommended by O&M staff. These include:

- Baby Creek screens (see Section 6.2.7.3)
- Hubbell Southfield dewatering pumps (see Section 9.2.7.3)
- Leib fine screens (see Section 8.2.1.3)
- St. Aubin dewatering pumps (see Section 14.2.7.3)

5.4.10 Automatic Transfer Switch and Generators Controls Upgrade

Seven CSO facilities have standby generators (i.e., Belle Isle, Conner Creek, Hubbell-Southfield, Leib, Puritan-Fenkell, Seven Mile, and St. Aubin). The reliability of these generators and automatic transfer switches (ATS) has declined over recent years. During utility power outages when the standby generators are necessary, either the generators do not start automatically, or the ATSs do not transfer. In addition, the generator control panels and the ATSs do not report status or alarm signals to the operators through the SCADA Ovation control system.

The “Automatic Transfer Switch and Generators Controls Upgrade” project is an ongoing project that will address these issues. Under this project, the CSO facilities with standby generator systems will be upgraded to have a standardized, dedicated automatic transfer control system. In addition, the project will include the following:

- 1) The PLCs or other controller styles will be replaced with modern, standardized, microprocessor-based automatic transfer controllers.
- 2) The front panel of ATS panels not being fully replaced will be reconfigured to be standardized across all CSO facilities. A remote human-machine interface (HMI) screen dedicated for the automatic transfer system will be provided.
- 3) Local generator panels will be evaluated for compatibility and reliability.

- 4) Ovation displays will be standardized and useful inputs (alarms, configuration, status) will be included.

5.4.11 Study for Disabled Motor Moisture Detection Capabilities

Throughout many of the CSO Facilities, motor moisture detection used for mixers and dewatering pumps has been disabled using wire jumpers to bypass the shutdown control circuits. While this practice could be considered acceptable during emergency situations, the problem comes from not removing the wire jumpers after the CSO event and correcting the underlying moisture problem in the motors. As time goes on, these jumpers are forgotten about, as well as additional, new jumpers being added for other motors. Jacobs recommends a study of all facilities to identify the location of all existing jumpers used on the motor moisture detection circuits and then develop a plan to remove the jumpers and correct the motor moisture detection issues.

5.5 Structural

A Structural Rehabilitation Needs Assessment, dated August 2018, was conducted by NTH Consultants for all nine CSO facilities under a separate project. In this assessment, NTH assessed structural defects in aboveground buildings and belowground structures. The purpose of this assessment was to provide bridging documents for an upcoming CSO Structural Rehabilitation design/build project, which is scheduled to begin in early 2021. As such, it is not considered a complete list of all the structural defects. The selected design-build firm will be generating an updated, more complete list of defects at the start of their project. Because the structural assessment will be completed soon, structural rehabilitation capital costs are not presented in this report.

5.6 Building Roofs

A Roof Asset Condition Assessment, dated July 19, 2018, was conducted by NTH Consultants under a separate project for eight of the nine CSO facilities. (Puritan-Fenkell was not included in the assessment because a planned roof replacement was out for bid at the time of the inspections). The purpose of this assessment was "to visually examine the facility roofs, determine needs and priorities, and recommend optimal remedial roofing work strategies that will ensure a maximum return on investment and optimize the use of facility maintenance funds." The assessment included the size (in square ft) of each roof, roof membrane type or composition, slope, year installed, roofing contractor, roof system manufacturer, and roof condition/service projection. Each roof was rated good, fair, or poor. The results of the 2018 roof assessment are included in Volume 6 – Appendices, Appendix H.

The results of the roof condition assessments were used by the CS-299 team to populate the condition of the roofs for each facility in CS-299 Condition Assessment. In some cases, the roof has been replaced since the assessment; these scores have been adjusted accordingly.

5.7 Safety

5.7.1 CSO Facility Safety Inspection

Under CS-299, Jacobs conducted a safety inspection of all the CSO facilities in January 2020. The purpose of the safety inspection was to identify safety-related issues. The report identified whether the issue should be addressed through a future capital improvement or non-capital projects. The findings of the safety inspections were presented in the CSO Facility Safety Inspection Report, dated March 30, 2020, included in Volume 6 – Appendices, Appendix E.

5.7.2 Safety-Related Capital Improvement Projects for Each Facility

Safety-related capital improvement projects at the CSO facilities generally fall into one of the following categories:

- 1) Fall Protection Improvements – the approach for fall protection and recommended improvements are discussed in Section 5.7.3.
- 2) Eyewash and Emergency Shower Improvements – to be included in each facility Safety cost estimate.
- 3) Exit Sign Improvements – see discussion in the following paragraphs for proposed project to address these issues.
- 4) Conner Creek Conveyor Improvement – See Conner Creek Screening section (Section 8.2.1.2) for project that is addressing this issue.

Emergency Lighting: Emergency lighting issues identified in the Safety Inspection Report are not included in the capital improvement projects since it is understood by Jacobs that these issues will be addressed in the recently completed LED Lighting Project.

Exit Sign Improvement Project: Illuminated exit signs and emergency lighting were not functioning or not present at many locations. Emergency lighting is being addressed in the ongoing LED Lighting Project. The emergency lighting project may provide illumination of exits in various locations, thus affecting the exit locations that need to be addressed in this project. Also, some of the exit sign bulbs may simply need to be replaced. As such, it is recommended that Exit Sign Improvement projects include an exit route survey at each facility meeting NFPA 101 (Life Safety Code) requirements, Michigan Building Code requirements (2015 ver.) and MIOSHA regulations. This task is being addressed in a separate project under Task Order Engineering Services (TOES). As such, capital costs are not included in this section.

Safety-related capital improvement projects are recommended for each individual facility. The detailed cost estimates in Volume 6 – Appendices, Appendix C provide the safety-related items included for each facility.

5.7.3 Fall Protection Improvements

Using the information presented in the Safety Inspection Report, preliminary recommendations for improvements at each hatch opening were generated. These are included in Table E-1 in Volume 6 – Appendices, Appendix E. The purpose of this table is to provide a basis for the project cost associated with fall protection. Design of some of the safety recommendations will be required, and, therefore, the costs may change in the future.

The following general approach was used for the preliminary recommendation at each hatch opening:

- 1) In general, permanent railings are preferred since they provide the most reliable protection. This includes most roof access hatch locations. It also includes other locations where there are no traffic or access issues. However, permanent railing are not practical at all locations due to the need to maintain traffic or access. These locations need to consider some other form of fall protection.
- 2) For hatch openings for equipment removal, where permanent railings are not practical, GLWA O&M staff has requested that nets be provided.
 - For equipment openings with double leaves where each side is at least 3.5 ft high (42-in.) when opened, chains could be added to the existing leaves at the top and middle. This would provide fall protection for these hatch openings.

- For equipment openings where the hatch leaves are not 3.5 ft high, Jacobs recommends temporary/portable railings be provided to protect other staff at locations where the hatch could be left open and the net pulled back for equipment removal for an extended period of time. The temporary railings can be either custom-made railings from a local fabricator that slide into cored holes in the floor (for inside locations only), or they could be standard portable railings purchased from a handrail manufacturer.
 - If temporary railings are not acceptable for these equipment openings, Jacobs recommends that D-rings be used in conjunction with staff in a safety harness to provide fall protection for the worker while removing/installing equipment.
- 3) For hatch locations for ladder access into confined spaces (i.e., basins or vaults), a portable davit in conjunction with a worker safety harness is recommended, as the davit provides both fall protection and aids in personnel rescue, if needed. A ladder ratchet system could also be used for fall protection; however, it is not as effective for retrieval.
 - 4) All ladders should have retractable safety posts at the top of the ladder for improved safety when entering or exiting the opening.
 - 5) At Conner Creek at the time of the Jacobs safety walk-through, it was noted that many small (2 ft by 2 ft) hatches for lighting in the basin were left open. Netting is recommended at these locations as a permanent safety measure, as well as D-rings to provide fall protection during light bulb replacement.

In addition to fall protection, other modifications or enhancements are needed at some hatches to address various deficiencies. These issues are included in the “Additional Items” column of the spreadsheet and should be more thoroughly evaluated during the detailed design for modifications to the hatches at each facility. The most notable modifications include:

- 1) Replacing the 16 plates over the mixers at Leib with hatches.
- 2) Re-orienting the basin access hatches, as necessary, to make closing the hatch safer. See Figure 5-9 for an example at Belle Isle basin where staff must reach across opening to actuate the red handle to close the hatch.

Figure 5-9. Example of Need for Re-orienting the Basin Access Hatches

- 3) Replacement of the cylinders to aid hatch opening and closing should be evaluated at the time of replacement of all hatches.
- 4) Installation of a ladder safety system or personal fall arrest system for existing fixed ladders over 24 ft in height by November 18, 2036, for any section of the fixed ladder/cage/well that is replaced, or for any new fixed ladder exceeding 24 ft in height, per revised OSHA standard 1910.28(b)(9). Existing cages on ladders will require replacement with an alternate fall arrest system or ladder safety system to meet the revised standards.
- 5) A preliminary list of ladders with cages are presented in Table E-1 in Volume 6 – Appendices, Appendix E. It is recommended that the replacement of existing ladder cages be included in future capital improvement projects between now and 2036, and as such, cost estimates are not included in this assessment.

Other fall and trip hazards were present at several locations. These are listed in Table E-1 in Volume 6 – Appendices, Appendix E. Many of these hazards can be addressed with the addition of fall protection features such as temporary railings and are generally included in the cost estimates for each facility. Note, that since the safety inspection report was issued in March 2020, Jacobs was notified by GLWA that swing gates are current practice – chains are not acceptable fall protection. The project costs for fall protection for each individual facility are presented in the facility-by-facility Safety sections.

5.8 Maintenance Work Order Review

The CS-299 CSO Facilities Assessment scope of work required Jacobs to review historical maintenance work orders (WOs) as one component of the Facilities Assessment. The purpose of this review was to determine whether useful information can be obtained from the WOs to aid in the identification of future improvements to the assets, specifically related to capital improvements. For example, if there is evidence within an asset's work order history that pointed to recurring problems, this evaluation could potentially identify that asset to be a candidate for capital improvement to address the issue.

The WO review, included in Volume 6 – Appendices, Appendix F, presents the findings from the review of historical maintenance work orders from 2013-2018. As indicated in the summary, this review did not provide significant information that is useful to determine the need for capital improvements to assets. While there are several WOs that address asset repairs, these generally appear to be normal wear items and do not indicate an installation or performance concern. Information from this review was used to compare reliability of chemical induction mixers.

6. Baby Creek CSO Control Facility

6.1 Facility Description and Future Capacity Considerations

6.1.1 General Facility Description

The Baby Creek CSO facility is a SDF with 3 million gallons (MG) of storage, and a treatment capacity of 5,100 cfs. It was constructed in 2006. The facility has a nearly 1-mile long effluent conduit used for disinfection contact time before discharge into the Rouge River. The facility consists of one main building with a large Headworks, Chemical Room, utility support (two Electrical Rooms and a Mechanical Room), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building near the end of the effluent conduit and outfall access at the Rouge River (Miller Road Gates).

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

6.1.2 Future Capacity Considerations

Based on a review of the WWMP and discussions with GLWA, there were no future increased capacity considerations identified at this facility.

The high water levels in the Great Lakes and Lower Rouge River, however, have created the need for using the bypass gates during peak flows of larger wet weather events, before the design-rated capacity of the screens is reached. This issue is further discussed in the Screening and I&C in the following sections.

6.2 Facility Assessment

6.2.1 Screening

6.2.1.1 Description of Existing System

The Baby Creek CSO facility has 16 perforated panel screens that were installed in 2006. The influent weir to the first four screens is set one foot lower than the remaining 12 screens so that only the first four screens are used during smaller storm events and lower flow periods. This means flows are preferentially sent through the Elmer Ternes barrel of the Outfall.

Soon after startup of the facility, the screens significantly blinded during a large wet weather event due to heavy leaf load in the influent wastewater. Water backed up in the sewer system causing flooding issues in the community upstream of the facility. Modifications were made to the screens to address this issue including running the units at high speed (VFDs were provided for the original system and are still installed, but now they are only run at high speed) and eliminating the start/stop control of the screens based on differential level. Currently, the screens are operated when the water level spills over the influent weir wall. Furthermore, a bypass channel was constructed around the screening and disinfection portion of the facility. This bypass channel can be and has been used when there was reported blinding of the screens during high flow events or when levels in the influent sewer are high.

The operators report that they have used the bypass about four to five times during the past two years, which is more frequent than in the past due to the unprecedentedly higher water levels in the Great Lakes over the past year. When the bypass gates are opened, the bypassed flow does not receive screening or

disinfection, making this a significant issue. Bypasses are considered a violation of the NPDES permit by EGLE.

Screenings from the screens discharge into a sluice channel. The screens are equipped with a rotating brush and spray water to aid in the removal of the screenings from the screen. Flushing pumps pump raw wastewater to the sluice channel to convey the screenings to the Toward Treatment Sewer.

Table 6-1 provides an overview of the existing screening system at Baby Creek CSO facility.

Table 6-1. Overview of Existing Screening System at Baby Creek CSO facility

Parameter	Value
Treatment Capacity (cfs)	5,100
No. of Screens	16
Manufacturer	US Filter – John Meunier (now Veolia)
Screen Type	Perforated Panel Screen
Opening Size	6-mm perforation
Depth or Length / Width	26 ft 6 in / 10 ft 0 in
Screen Cleaning	Brush and high-pressure spray
Screening Removal	Conveyed through sluice trough to Toward Treatment Sewer and to WRRF

6.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Improve existing screens for blinding and reliability. Note that the evaluation of screen blinding is presented in the next section. It was determined that blinding was not a major issue and does not require a capital improvement. During the investigation, however, a potential improvement to the screen brushes was proposed and is evaluated under Replace Existing Screen Brushes (Project BC-SCR-1).
- Evaluate maintenance access to Screen 5. Unlike the other 15 screens, Screen 5 is unable to tilt up to Headworks floor due to interference by a large tipping bucket. Jacobs contacted Veolia to obtain input on maintenance procedures for this screen, given this constraint. They indicate that this screen needs to be only slightly pivoted to make the lateral doors near the bottom of the screen accessible and work on the bottom elements (i.e., sprockets, stub shafts, bushing, etc.) needs to be performed in the channel. Based on this input, this issue is not evaluated further.

6.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with a recommended alternative.

Improve existing screens for blinding and reliability. Operations staff reported that the screens blind about twice per year, once in the spring and once in the fall. If blinding is occurring, it may be increasing upstream water levels such that bypassing of the screens is required, which is a permit violation.

An assessment of screen blinding was conducted under CS-299. SCADA data was collected for seven storms between July 2017 through January 2020 for water levels upstream and downstream of the

screens. This information was used to evaluate the level differential (i.e., upstream level minus downstream level) through the screen during the entire storm event. If the screens blind, the level differential through the screen will increase significantly compared to the rest of the event.

Table 6-2 provides a summary of the storms and the level differentials.

Table 6-2. Peak Total Influent Flow and Screen Level Differential During Storm Events

Storm Date	Peak Total Influent Flow (cfs)	Level Differential Throughout Storm (inches)
11/18/17	952	5 – 8
4/15/18	614	5 – 8
5/12/18	878	5 – 9
10/2/18	405	5 – 8
7/7/19	872	19 – 31
10/27/19	1149	6 – 7
1/11/20	1444	6

Figure 6-1 and Figure 6-2 show water levels upstream and downstream of the screens as well as the river elevation and flow for the two storm events in October 2019 and January 2020, respectively. The upstream water level is shown in light and dark green and the downstream water level is shown in red and magenta. The screen differential levels in Figure 6-1 and Figure 6-2 are representative of all of the storms except for the July 7, 2019, storm as discussed below.

Figure 6-1. Screen Differential Level during October 27, 2019 Storm

Figure 6-2. Screen Differential Level during January 11, 2020 Storm

Below are findings from analyzing the level differential data for all of the events.

- All events show a relatively constant differential across the screen during the entire storm event, regardless of flow rate throughout the storm. It should be noted that the differential through the screens should be greater during high flows and smaller during lower flows. The sensors should be checked for calibration as an annual recurring preventative maintenance (PM) activity.
- The differential varies from storm event to storm event; however, the value is nearly constant through an individual storm event. For example, differential was 6 in. for the entire January 11, 2020 storm and 6 to 7 in. for the October 27, 2019 storm. One storm (July 7, 2019), however, had differential of 19-31 in. throughout the storm event. This range was due to the fact that the influent level sensors had a 12- in. difference between the two readings for the entire event, which is not considered accurate.
- There are spikes in the level at the beginning of two events (May 11, 2018 [not shown] and January 11, 2020). These could be considered blinding caused by a first flush since the level rapidly increases, then decreases. In fact, for the January 11, 2020 storm, the bypass gates had to be opened at the beginning of the event. However, the downstream level shows the same spike. This indicates that blinding is not the cause of the spike in level. Rather, it is likely caused by the rapid increase in flow to the facility.
- The January 11, 2020 demonstrates that the river level affects the upstream levels. As noted on the figure (Figure 6-2) on January 12, 2020, an increase in the river level increases the downstream and the upstream screen levels.

Based on the constant level differential across the screens during large storm events, the screens do not show evidence of blinding. This issue was reviewed with GLWA on April 16, 2020. It was concluded that blinding was not occurring. As such, capital improvements intended to specifically reduce screen blinding will not be beneficial.

Replace Existing Screen Brushes (Project BC-SCR-1). During the investigation of the blinding issue and previous Veolia site visits, Veolia indicated that there is a new type of brush mechanism for the screens. The current mechanism is stationary, and a newer, current version of the mechanism is self-adjusting. All new screens of this type from Veolia have self-adjusting brush mechanisms. Reportedly, the self-adjusting brush maintains better contact with the screen panels at a constant pressure as the panels pass by the brush improving removal of screenings and extending brush life. The existing screen could be retrofitted with the new mechanism to potentially improve screenings removal and extend the life of the brush.

Due to the lack of supporting data related to the benefits of the newer brushes, GLWA could consider piloting the self-adjusting brush mechanism on two of the more frequently used screens (i.e., Screens 1 to 4) to compare its performance and the impact on brush life. Based on these results, GLWA would be able to determine whether to replace the brush mechanisms on the remaining screens. As such, there are two alternatives with this option:

- 1) **Alternative 1: Replace Existing Brushes In-Kind.** Replace with stationary brushes for two screens.
- 2) **Alternative 2: Pilot Self-Adjusting Brushes.** Replace with self-adjusting brushes for two screens.

The alternative evaluation is presented in Table 6-3. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 is based on brush costs from Veolia from a recent brush replacement order in 2019. Cost is for two brushes, installed by GLWA maintenance.

- The capital cost for Alternative 2 are included in Volume 6 – Appendices, Appendix C, under this project title, and are based on a quote for two brushes. Installation of the brushes is assumed to be performed by a contractor.

This analysis does not account for a potentially longer life of the brush, which would be determined through the pilot evaluation. Review of the NPV/Benefit costs, however, shows that the self-adjusting brushes would need a longevity of approximately four times longer than the existing brushes to be considered the Best Value Alternative. It is not anticipated that the self-adjusting brushes would have a longevity long enough to be considered the Best Value Alternative. As such, **Alternative 1: Replace Existing Brushes In-Kind is the recommended alternative.** Because this should be considered a wear item, it is not included in the capital improvement projects; rather, brush replacement should be included in a Capital Outlay for these screens.

Table 6-3. Alternative Evaluation for Replace Existing Screen Brushes (Project BC-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Screen Brushes In-Kind	Health and Safety	3	2.40	\$ 36,000	\$ -	\$ 36,000	\$ 15,000	Best Value Alternative
	<i>Definition:</i>	Replace existing screen brushes in-kind when they have worn	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Shorter brush useful life due to higher wear rate. Not as effective at cleaning the screen.	Component Performance	2						
	<i>Comments:</i>	Brush costs from Veolia. Assumes GLWA labor for installation.	O&M Ease	2						
2	<i>Alt. Name:</i>	Pilot Self-Adjusting Brushes (Two Screen Pilot)	Health and Safety	3	3.00	\$ 173,000	\$ -	\$ 173,000	\$ 57,667	
	<i>Definition:</i>	Install higher performance self-adjusting brushes.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher cleaning performance. Longer life due to less wearing.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	Although new brushes may last longer than existing bushes, this evaluation assumes the new brushes have the same useful life.	O&M Ease	3						

6.2.2 Disinfection

6.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of four rubber-lined steel tanks, eight self-priming centrifugal pumps with VFD speed control, eight disinfectant rapid mix zones, and 32 induction mixers. There are 16 screens and the flow from each pair of screens is funneled into a disinfectant rapid mix zone. There are four induction mixers per disinfectant rapid mix zone consisting of two low level mixers and two high level mixers. The sodium hypochlorite pumps discharge to two headers, one smaller than the other, which run the length of the Headworks and each connect to the manifold feeding the four induction mixers at each rapid mix zone. Flow splitting between the four induction mixers is not metered and is dependent on functioning back pressure valves with equal upstream pressure settings.

Table 6-4 provides an overview of the existing disinfection system at Baby Creek CSO facility and the disinfection process flow diagram is included in Volume 6 – Appendices, Appendix G.

Table 6-4. Overview of Existing Disinfection System at Baby Creek CSO facility

Parameter	Value
Treatment Capacity (cfs)	5,100
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L as Cl ₂)	20
Disinfection Contact Time (min)	10
Storage Tanks	
Number	4
Volume of Each Tank (gal)	36,000
Type	Rubber-lined steel
Pumps	
Number	8 Total; 2 low-rate, 3 mid-rate, 3 high-rate
Capacity (gpm)	Low-rate: 0-50, Mid-rate: 0-150, High-rate: 0-400
Type	Centrifugal
Mixers	
Number / Type	32 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC15XPL/ 15 hp / Water Champ

6.2.2.2 Identified Needs and Issues

The needs and issues for Baby Creek were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Baby Creek chemical feed system has the following issues:
 - The pumps and pipe supports in the vicinity of the pumps are corroding as a result of exposure to sodium hypochlorite.
 - A glued polyvinyl chloride (PVC) joint fails at an approximate rate of one every three months in the Chemical Room.

- The pumps have traditional drives requiring seal water, are reaching the end of their useful life, and include self-priming accessories adding to their complexity and increasing their footprint.
- The chemical piping is complex and congested.
- The back pressure valves controlling the chemical feed split between the four induction mixers at each disinfectant rapid mix zone are suspected of not functioning properly.

These issues are addressed in Replace Chemical Feed System (Project BC-DIS-1) in the next section.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BC-DIS-2) in the following bullet.
- There are 32 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3).
- Inefficient mixer removal system – includes evaluation of monorail vs. gantry cranes with electric hoist and electric trolley to replace existing hand chain hoist. This issue is addressed in Improve Mixer Removal System (Project BC-SUPP-1) at the end of this facility section.
- Modify floor slope in Chemical Room to drain to sump – This issue is addressed in the Architectural section (Section 6.2.9.3).
- Reline chemical storage tanks – Based on an inspection in 2020, the tanks are in need of relining to provide extended life. The repair/replacement of the liner is an ongoing project, so it is not included in the capital improvement projects for CS-299. The SRP model was manually adjusted to recognize the improvement of this ongoing project.
- Related to the relining of the storage tanks, GLWA requested that Jacobs review the historical and expected chemical usage compared to tank storage capacity to determine whether to reline all four tanks or only two or three tanks. Sodium hypochlorite usage for the four largest storms from 2016 through early 2019 was evaluated. The volume used was based on tank levels rather than flow meters because of suspicious flow meter data. The analysis indicated that the maximum used as a percent of total tank volume was 49 percent. This would indicate that the minimum number of tanks to be relined would be two. Had a larger storm occurred than the period analyzed then more than two tanks would be required assuming all other things equal (i.e., assuming the same dose and hypochlorite strength). Using more conservative assumptions of a 15 mg/L average dose and an assumed 5 percent hypochlorite strength, a volume in excess of the total four tank volume would be required. At an assumed dose of 15 mg/L and 9 percent hypochlorite strength three tanks would be fully consumed. Given the possibilities of a larger storm, hypochlorite degradation down to 5 percent, or the need for a higher dose, it is recommended that all four tanks be relined to retain the original design capacity at Baby Creek.
- Sump pump replacement in Chemical Room – This is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.
- Chemical make-up water actuator replacement in Chemical Room – This is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.

6.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project BC-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, BC-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 6-5. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital costs for Alternative 2 and 3 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 was developed based on GLWA experience of two pump rebuilds per year at a cost of \$13,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 6-5 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 6-5. Alternative Evaluation for Replace Chemical Feed System (Project BC-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 1,657,301	\$ 26,000	\$ 2,205,631	\$ 1,058,703	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with feeding too much chemical. System is unique to Baby Creek.	Component Performance	1						
	<i>Comments:</i>	Capital costs include pump replacement at Year 10	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 3,325,000	\$ 44,550	\$ 4,264,543	\$ 1,184,595	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per disinfection channel. Utilize hose pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual switchover.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 1,237,000	\$ 4,000	\$ 1,321,359	\$ 367,044	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps connected to all disinfection channels. Utilize centrifugal pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily utilized.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each disinfection channel.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BC-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Operation in manual at Baby Creek is noted by operations as being extremely difficult. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time must also be considered. The exact location would be determined during design. Based on the evaluation of a few years of recent data, the average flow rate during storms at Baby Creek is about 108 cfs. This is a very small percent of the design storm and 15 minutes contact time at average flow will be only a short distance downstream of the dose point (approximately 500 ft). The sampling location needs to be upstream of storm sewer flows which would dilute the measurement. If there is an existing access point that meets the criteria, then this should be explored during design. However, the cost of a new manhole will be assumed to access the sampling pump.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 6-6. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be consistently met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 6-6. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project BC-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 201,000	\$ 4,860	\$ 303,496	\$ 87,970	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	O&M to maintain analyzers based on 3 hrs/month.	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3). Plant personnel reported that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. These issues are exacerbated by having 32 mixers at Baby Creek, which is the second-highest of the nine CSO facilities. A reduction in the number of mixers would reduce maintenance and the associated expenses proportionate to the reduction. It would also reduce the complexity of equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4). The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** CFD modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from four to two per channel) based on the fact that the latest model shows design flows are about half of the original design flows.
- 3) **Alternative 3. Install Vertical Shaft Mixers.** This alternative would replace the existing chemical induction mixers with new vertical shaft mixers. For Baby Creek, two mixers would be provided per channel.

The alternative evaluation is presented in Table 6-7. The sources of costs used in this evaluation are listed in the following bullet:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$18,000 per mixer.
- The capital cost for Alternative 3 (vertical shaft mixers) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 (vertical shaft mixers) are based on expected maintenance costs, including changing oil, greasing bearings, periodic rag removal from the shaft and servicing the steady bearing.

As shown in Table 6-7, Alternative 2 has a Total Benefit score about 0.4 higher than Alternative 1 because of the improved ease of maintaining fewer mixers. Alternative 3 has a Total Benefit score about 0.3 higher than Alternative 2 based on the anticipated improved performance of the vertical mixers and improved ease of maintenance, since the mechanical portion of above the water surface. **Alternative 2, however, has the lowest NPV/Benefit cost and therefore, is the recommended alternative.**

It should be noted that the cost of the reduced mixers is not a new capital cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection performance can be achieved, the vertical mixer alternative should be further explored, possibly through the pilot testing of this technology in one of the channels at Baby Creek or Conner Creek.

Table 6-7. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project BC-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Induction Mixers In-Kind	Health and Safety	3	2.57	\$ 3,200,000	\$ 230,400	\$ 8,059,052	\$ 3,139,890	
	<i>Definition:</i>	Replace existing mixers as required.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, lots of redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Expensive and impacts operations and maintenance. Equipment installed in channels. Possible ragging issues.	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period.	O&M Ease	1						
2	<i>Alt. Name:</i>	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	Health and Safety	3	3.00	\$ 1,650,000	\$ 115,200	\$ 4,079,526	\$ 1,359,842	Best Value Alternative
	<i>Definition:</i>	Perform CFD modeling to simulate performance with fewer mixers (assumed 50% of existing).	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less expensive and less impacts to operations and maintenance. Equipment installed in channels. Possible ragging issues.	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period & CFD Modeling of \$50,000.	O&M Ease	3						
3	<i>Alt. Name:</i>	Install Vertical Shaft Mixers	Health and Safety	3	3.32	\$ 7,033,000	\$ 56,000	\$ 8,214,020	\$ 2,476,589	
	<i>Definition:</i>	Replace existing mixers with vertical shaft mixers.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less equipment to operate and maintain. Overall less install horsepower. Equipment is above the basin and accessible in a non-confined space environment. Maintains redundancy requirements.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Bearing in bottom of channel. Possible ragging issues.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.3 Odor Control

6.2.3.1 Description of Existing System

The Baby Creek odor control system is a Calgon Carbon PHOENIX automatic regeneration system, which utilizes radial flow canisters filled with Centaur HP carbon. Several years ago, Calgon Carbon sold its odor control equipment division to Continental Carbon along with the Centaur HP carbon. The unit consists of 26 compartments of five canisters each for a total of 130 canisters. Foul air is delivered from the Screening Building by the odor control fan and is uniformly distributed through the carbon canisters, bringing the air in direct contact with the carbon. Centaur HP carbon contains a catalyst that oxidizes hydrogen sulfide (H_2S) and converts it to sulfuric acid. As a result, the carbon can be restored for H_2S uptake by water washing. The regeneration process consists of filling a single compartment of canisters with water, letting the water sit for a period of time, and then draining and drying the carbon. The system was installed in 2006. The carbon has not been replaced since installation.

This odor control system operates under air permit requirements (Permit to Install No. 69-90). The emission limit is 0.04 pounds per hour of H_2S . At a design air flow of 26,000 cubic feet per minute (cfm), this equates to approximately 0.3 parts per million volume concentration of H_2S . The permit does not require sampling of emissions of carbon media unless the Michigan Department of EGLE specifically requests it.

Per GLWA, no odor complaints have been received for at least the past three years.

6.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendations in this section are based on the Jacobs team evaluation of the existing system.

Future Carbon Replacement Considerations. Carbon eventually needs to be replaced when the capacity to remove H_2S diminishes to the point that the discharge does not meet permit limits. Carbon replacement can be expensive, and the frequency and type of carbon should be carefully considered. This section presents considerations for carbon replacement.

The Centaur HP carbon loses capacity over time for several reasons. The main mechanism is loss of adsorption sites due to compounds other than H_2S . Other odorous compounds like organic sulfide compounds remain adsorbed to the carbon and are not removed during the regeneration process. Chlorine and other compounds that may be present in the regeneration water will adsorb to the carbon and remain. Another mechanism is residual sulfuric acid that does not get rinsed during the regeneration cycle and remains on the carbon occupying sites. Finally, carbon fines (i.e., tiny pieces of the carbon media) are lost over time as a result of the repeated washing process. The loss of fines reduces the carbon volume, which, correspondingly, reduces the carbon's overall capacity. One typically determines the need for carbon regeneration by measuring the H_2S concentration in the discharged air. When H_2S is still detected in the discharged air after a regeneration cycle, the carbon is spent and should be replaced. Centaur HP replacement is about every two years under typical municipal wastewater applications. GLWA facilities are not typical applications as the odor control systems are operated infrequently and are likely under low loads from H_2S and odorous compounds meaning the carbon will last a lot longer. According to O&M staff, the Baby Creek system is regenerated twice per year based on the recommended PM in the manufacturer's O&M manual. If this frequency has occurred since startup, the system has been washed about 24 times. Under extremely low odor loads, the carbon can be depleted faster due to compounds in the regeneration water like chlorine. Laboratory analysis of the carbon for H_2S capacity is likely the best

way to determine the remaining carbon life for the Baby Creek system. Sampling the discharged air for H₂S breakthrough likely will not be effective due to the likely low H₂S load.

Although the current carbon capacity may be significantly less than the original capacity, the lack of any odor complaints from the community means that any odors being discharged are either not noticeable, not objectionable or are masked by other odor sources in the area. It is recommended that GLWA sample the influent and discharge of the odor control system during at least two storm events in the summer months (i.e., the period with the highest odor potential) to better understand the magnitude of odors generated from the CSO facility and the performance of the current system relative to the existing air permit limits.

If the influent H₂S levels are below discharge permit limits, replacement of the carbon would not be needed. Further testing could then be performed to determine if the carbon could be removed and not replaced. If influent and discharge H₂S levels are greater than permit limits, carbon replacement should be performed in the near future. The following bullets provides considerations for the carbon replacement.

- The existing Centaur HP carbon in the PHOENIX system has an H₂S capacity of 0.09 g H₂S/cubic centimeter of carbon (15 percent by weight). The cost for replacement of the carbon is about \$88,400 (130 canisters at \$680 per canister). The cost includes a new canister, sealing and loading the canister with Centaur HP carbon, and delivery.
- ECS Environmental Solutions (ECS) manufactures a direct equivalent to Centaur HP carbon at a lower cost. ECS reuses the existing canisters. The cost for ECS's water regenerable catalytic carbon is about \$55,250 (130 canisters at \$425 per canister). The cost includes shipping the full canisters to ECS, disposal of the spent carbon, cleaning the canisters, charging the canisters with ECS water regenerable catalytic carbon, and delivery.

As noted above, an evaluation of influent and discharge H₂S concentrations is recommended prior to carbon replacement. When it is time to replace the Centaur HP carbon, GLWA should evaluate replacing it with either Centaur HP or ECS water regenerable catalytic carbon.

6.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs".

6.2.4 Flushing and Dewatering

6.2.4.1 Description of Existing System

Dewatering System: After an overflow event, the effluent conduits and headworks area are dewatered by gravity by opening the sluice gates S-6-1 and S-6-2 to the Oakwood Interceptor. A 3,000 gpm dewatering pump is provided in the flushing pump area to fully dewater the Headworks area.

An alternate mode of dewatering is to allow the screening flushing pumps to continue to operate following an overflow event. This method of dewatering will allow dewatering flow into the Oakwood Interceptor even when the hydraulic grade line is relatively high.

Flushing System: A flushing system for the area in the Headworks upstream of the screens consists of two tipping buckets. There is one tipping bucket upstream of Screens 1-4 and one tipping bucket upstream of Screens 5-16.

It is noted that a flushing system is not currently provided for the effluent conduits. The nearly 1-mile long effluent conduits have an issue with significant quantities of solids accumulating in the channels (i.e., up to 5 ft deep in some locations). GLWA televised these conduits in 2019. GLWA plans to issue an RFP to address this issue in the near future. As such, this issue is not further addressed in this report.

Table 6-8 provides an overview of the existing flushing and dewatering system at Baby Creek CSO facility.

Table 6-8. Overview of Existing Flushing and Dewatering System at Baby Creek CSO facility

Parameter	Value
Headworks Dewatering and Flushing System	- One 3,000 gpm submersible pump for station dewatering (in Dewatering Sump) - Four 16,000 gpm submersible pumps - typically for screenings conveyance, but can be used to dewater area upstream of screens 2 tipping buckets for the area upstream of screens. Buckets flush toward Dewatering Sump, which pumps to Toward Treatment sewer
Effluent Conduit Dimensions	Three 17.5 ft × 14.5 ft barrel conduits
Effluent Conduit Dewatering and Flushing System	- Sluice gates at end of conduit are used to dewater effluent conduit to the Oakwood Interceptor after storm event. - There is no flushing system in the effluent conduit. <i>Project for a flushing system anticipated in the near future</i>

6.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids can accumulate in the influent channel area, immediately upstream of the weir wall at the Headworks. Significant solids buildup can cause hydraulic restrictions and impede inspection of influent flow meters. There is no flushing system at this location and solids removal must be performed periodically by a contractor. A contractor recently cleaned the influent channel area in 2019.
- S-2-1 sluice gate opening does not extend to the bottom of the influent channel to allow for complete dewatering (or solids flushing) of the influent area.
- Address sediment buildup in effluent disinfection conduits. Significant sediment occurs over time in the effluent conduits. An RFP for professional engineering services to minimize the buildup of sediments is planned in the near future to address this issue. As such, it is not included as a capital improvement project for CS-299.

6.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing System in Influent Area (Project BC-FD-1). There are two alternatives for addressing the solids buildup in the influent area and the S-2-1 sluice gate opening. These alternatives include:

- Alternative 1: Do Nothing/ Contractor Clean-Out.**
- Alternative 2: Flushing System in Influent Area.** An identified alternative includes mounting a 6- in. high-density polyethylene (HDPE) flushing header along the backwall of the influent area

approximately 8 ft above the adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B for figures (Figure BC-FD-1-ALT-2) showing conceptual layouts of this header. HDPE pipe is recommended for this application due to its corrosion resistance and its flexibility that imparts resistance to damage from impacts by heavy debris suspended in wet weather flows. The flushing header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 3/4- in. diameter) that create a water jet aimed in a specific direction toward the opening of Gate S-2-1. This gate is normally closed during dry-weather operation. A subsequent project to lower the invert of this opening is included in this set of recommendations.

The proposed hole spacing along the header is approximately 18 to 24 in. A total flow rate of at least 900 gpm is estimated to adequately remove sediment from the concrete shelf above the dry-weather flow channel and maintain adequate volume and velocity to carry the sediment into the dry-weather flow channel post event.

A second HDPE header mounted approximately 5 ft above the dry-weather flow channel with a similar spray hole distribution is recommended to provide additional flow and increase velocity during flushing. This will encourage faster removal and migration of sediment to the reconfigured Gate S-2-1 opening for pumping with the existing dewatering pump and discharge toward the WRRF with its better capacity for solids removal and disposal. A total flow rate of 1,200 gpm is estimated for initial sizing of this header. The benefit of the drilled hole approach to directing a jet of water is that no fittings are mounted on the exterior, and the pipe wall provides enough apparent length such that the hole directs the flow toward the intended surface.

Non-potable water (NPW) will be required. A 6-in. NPW line exists within the Headworks facility and is currently used for screen spray water and for chemical line flushing. The proposed flushing system connection could be made to this existing line within the facility. Flushing of the influent channel should occur after facility flows have significantly receded. As such, the influent flushing water use will not conflict with these other uses.

Following a CSO event, a motor operated solenoid/gate/ball control valve at the NPW pipe connection to the flushing water system will be opened to charge the flushing header. The control strategy assumes that solenoid is activated for a set duration (minimum of 15 minutes) after the level sensors in the influent channel record a water level rise above a pre-determined wet weather elevation and then a subsequent water level drop. A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying. Weekly automated cleaning during dry weather periods using this system will help reduce buildup of materials on the shelf and in the dry-weather flow channel.

During initial operation, onsite staff should visually inspect the shelf area to confirm sediment has been adequately removed and then adjust the control system timer to increase/decrease the flushing duration as needed until the system has been optimized. Integration with the facility's SCADA and PLC systems is necessary to achieve this functionality. A new electrical connection to the control valve is also required (110 V) and would be routed from the nearest internal junction box.

The opening for the S-2-1 gate does not extend to the floor of the influent channel. Making the bottom of this gate opening at a lower elevation would allow for flushed solids to enter the dewatering well and staff to be able to dewater the area without using sump pumps. The opening of sluice gate S-2-1 could be modified by removing the existing gate and frame, cutting approximately 2 ft of concrete from the bottom of the opening and remounting a new larger sluice gate.

The existing dry-weather flow channel will require addition of concrete topping to form a positive slope toward the expanded Gate S-2-1 opening, as shown in the drawings. The final designer should

collect and characterize site-specific sediment samples for grain size and density, and use a sediment fate/transport, CFD or scale model to finalize the performance criteria. This will be critical in evaluating and sizing this system to determine the required flow rate to direct sediment and the dry-weather base flow (20-30 cfs) toward the opening of Gate S-2-1.

The opening for the S-2-1 gate does not extend to the floor of the influent channel. Making the bottom of this gate opening at a lower elevation would allow for flushed solids to enter the dewatering well and staff to be able to dewater the area without using sump pumps. The opening of sluice gate S-2-1 could be modified by removing the existing gate and frame, cutting approximately 2 ft of concrete from the bottom of the opening and remounting a new larger sluice gate. Subsequent to the draft Facilities Assessment Report, another consultant (AECOM) analyzed this proposed flushing arrangement using CFD modeling and found that the proposed flow rate in the trough did not significantly suspend sediment within the influent trough. Based on this input, GLWA elected to postpone this project further into the future (at least 10 years out) and re-evaluate again after another round of manual cleaning.

For reference, the alternative evaluation for these alternatives is presented in Table 6-9. The sources of costs used in this evaluation are listed in the following bullets:

- Contractor clean-out of this area is estimated to be \$250,000 every 5 years, based on the cost and amount of solids buildup from the recent cleaning project at this location. This O&M cost is annualized to \$50,000.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$90,000 for cleaning the influent channel prior to installing the flushing system. The \$90,000 equates to about \$250,000 after contingencies, and standard markups for design, construction assistance and contractor overhead and profit have been applied.
- The O&M costs for the flushing system (Alternative 2) is based on water usage of 2,100 gpm for 15 min every week, for a total of about 1.6 MG per year and a unit cost of \$4,000 per MG.

Based on the results of recent CFD modeling of the flushing system by others showing that the sediment is not significantly suspended, **Alternative 1 – Contractor Clean Out is the recommended alternative.** Although Alternative 2 is not recommended at this time, it is included in the CIP to be reconsidered in about 10-15 years based on experienced gained from contracted cleaning the influent channel.

Table 6-9. Alternative Evaluation for Flushing System in Influent Area (Project BC-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Contractor Clean-Out	Health and Safety	2	2.50	\$ -	\$ 50,000	\$ 1,054,482	\$ 421,793	
	<i>Definition:</i>	Allow solids to build up and have a Contractor clean out the channel, as needed	Water Quality & Compliance	3						
	<i>Adv.:</i>	No system to maintain	Capacity Enhancement	3						
	<i>Disadv.:</i>	Significant build-ups can impact facility hydraulic capacity. Cleaning influent area is a high-risk activity. Requires a great deal of GLWA coordination.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing System in Influent Area	Health and Safety	5	3.78	\$ 787,000	\$ 6,400	\$ 921,974	\$ 243,693	Best Value Alternative
	<i>Definition:</i>	Mount a flushing header along the backwall of the influent area and second flushing header above the dry weather flow channel	Water Quality & Compliance	3						
	<i>Adv.:</i>	Allows flushing after every event.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance of equipment and increased water usage.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.5 HVAC

6.2.5.1 Description of Existing System

The Baby Creek CSO facility was constructed in 2006. The facility consists of one main building with a large Headworks, Chemical Room, utility support (two Electrical Rooms and a Mechanical Room), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building about a mile from the main building. Table 6-10 provides a summary of the major HVAC equipment at this facility.

Plumbing services for the facility consist of city water service, sanitary system, natural gas-fired water heater, electric water cooler, emergency shower/eye wash, emergency eye wash, and bathrooms with lockers and shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 6.2.10.

Table 6-10. Major HVAC Equipment at Baby Creek CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HV-1 & 2	2 × Heating and Ventilating Units	31,000 cfm and 1,760 MBH
	SF-1, 2, & 3	3 × Supply Fans	45,000 cfm
	EUH-1A to H	8 × Electric Unit Heaters	2,450 cfm and 51.2 MBH
Chemical Room	GUH-5A to 5E	5 × Gas Unit Heaters	1,100 cfm and 60 MBH
	IF-1	Exhaust Fan	2,110 cfm
	IF-2	Exhaust Fan	10,551 cfm
Electrical Room 1	WF-1	Wall Fan (Exhaust)	6,320 cfm
	EUH-2	Electric Unit Heater	700 cfm and 25.6 MBH
Electrical Room 2	WF-2	Wall Fan (Exhaust)	1,000 cfm
	EUH-3	Electric Unit Heater	400 cfm and 17.1 MBH
Control Room	HVAC-1	AHU with Split DX Cooling Coil and Natural Gas Furnace	1,610 cfm 74 MBH Heating 43.5 MBH Cooling
Office	HVAC-2	AHU with Split DX Cooling Coil and Natural Gas Furnace	1,480 cfm 74 MBH Heating 43.5 MBH Cooling

Notes:

AHU = air handling unit(s)

BTU = British thermal units

MBH = thousand British thermal units per hour

Table 6-11 provides a summary of the basis of design performance criteria for HVAC systems at Baby Creek and Table 6-12 provides the outdoor Basis of Design conditions.

Table 6-11. Baby Creek Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks	Class I, Div 1, Group D	60	N/A	12 ACH (Occupied)
Chemical Room	Unclassified	60	100	6 ACH (Cooling Mode) 1 ACH (Continuous)
Electrical Room	Unclassified	70	100	Heat Relief
Control Room	Unclassified	72	72	5 cfm per person & 0.06 cfm/ft ²
Office	Unclassified	72 (Occupied) 50 (Unoccupied)	75	5 cfm per person & 0.06 cfm/ft ²

Notes:

ACH = air changes per hour

cfm/ft² = cubic feet per minute per square feet

Outdoor Design Temperature		
Winter (Dry Bulb F)	Summer (Dry Bulb F)	Summer (Wet Bulb F)
3	91	73

6.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC Contractor, the following HVAC issues were noted:

- Inadequate heating in Control Building: O&M staff noted that when outdoor air conditions are under 20 °F, the furnaces (HVAC-1 and HVAC-2) serving the main Control Building struggle to maintain a setpoint of 70 °F indoors.
- Abnormally short life for Electric Unit Heaters in Headworks Area: Per GLWA's HVAC Contractor, the Electric Unit Heaters in the Headworks Area have a life of 2 to 3 years. The typical expected life of unit heaters which are properly selected for their environment is about 15 years.
- Corrosion issues with Gas Unit Heaters in Chemical Room: GLWA's HVAC Contractor has observed corrosion issues with the gas unit heaters in the Chemical Room. Additionally, the location of one unit over the pump area was noted as making access for maintenance a major issue.

During site investigations (June 2020) the following observations were noted:

- The Chemical Room unit heaters are difficult to access. See Figure 6-3.

Figure 6-3. Chemical Room Unit Heater Located in Inaccessible Area

- Corrosion was visible on unit heaters in the Chemical Room.
- The Transformer Room supplied outside air for ventilation cooling high in the space and exhausted at a low level.
- The large overhead doors were open in the Headworks Area, the relief dampers were closed, and the make-up air unit (MAU) was not running.
- The thermostat on EUH-1 in the Headworks Area was out of calibration.
- Unit heater EUH-2 was turned on in the Headworks Area and it was about 75 degrees outside.
- Corrosion was visible on Trane unit heaters in the Headworks Area.
- Several of the motorized outside air intake dampers for SF-1, SF-2, and SF-3 were not functional. The fans showed signs of significant corrosion.

Improvements are currently ongoing under existing projects including:

- The installation of a new intake louver with integral motorized damper and exhaust fan in the Electrical Room
- Damper motor actuator replacements in the Chemical Room
- Damper and actuator replacements in the Headworks Area
- Various monitoring and control upgrades including control and monitoring of electric unit heaters, fans, dampers and HVAC units.

6.2.5.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Control Building HVAC Investigation and Improvements Study (Air Balance Study). Given that the winter outdoor design condition for the units was 3 °F and that they were designed to heat to 72 °F, the furnaces are not functioning as intended.

If the ongoing controls upgrade does not improve heating at the facility, Jacobs recommends an air balance of HVAC-1 and HVAC-2 to assess whether poor air distribution is the cause of the observed underheating.

If the air balance does not improve heating in the under-heated areas, electric duct heaters can be added to branches of the system requiring additional heat.

Chemical Room Unit Heaters and Ventilation System (Project BC-HVAC-1). The Trane GAND model unit heaters in the Chemical Room have aluminized steel heat exchangers. Sodium hypochlorite is known to have a severe corrosive effect on aluminum. The use of natural gas unit heaters in a sodium hypochlorite environment is generally not recommended due to the potential for corrosion of the unit heaters and subsequent natural gas leakage. There are two alternatives to address this issue:

- 1) **Alternative 1: Replace Chemical Room Unit Heaters and Ventilation System In-Kind.** This alternative assumes the units will be replaced in-kind. Because of the corrosive environment of this room, the units will be assumed to be replaced more frequently than typical unit heaters, as discussed further in the alternative evaluation in the following paragraph.
- 2) **Alternative 2: Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit.** This alternative involves removing the gas unit heaters and installing an air handling unit (AHU) with a modulating gas heating section at ground level adjacent to the Chemical Room. The unit would be provided with a VFD to allow the AHU to work in conjunction with IF-1 to maintain a set differential pressure between the Chemical Room and ambient conditions. The AHU would run in conjunction with IF-1 and IF-2 in the summer to provide ventilation for cooling the Chemical Room. The AHU would run continuously at the minimum ventilation rate but would also be provided with a low leakage motorized damper which would close when the unit is not running (when the unit requires maintenance) to prevent backflow of air from the Chemical Room to the inside of the AHU potentially leading to corrosion issues. Locating the heating section in an AHU on the ground level has the added benefit of both reducing the number of pieces of equipment which need to be maintained and providing easier access to the equipment for maintenance personnel.

Figure BC-HVAC-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows a potential location for the AHU. It also shows that the road next to the Chemical Room would need to be slightly relocated to allow adequate room for the AHU. Road modifications are included in the capital cost for this alternative.

The alternative evaluation is presented in Table 6-13. The sources of costs used in this evaluation are listed in the following bullets:

- Capital costs for the unit heaters and ventilation units in Alternative 1 were obtained from the SRP. The costs for the six unit heaters were multiplied by 2, assuming the units would need to be replaced twice during the life cycle of the AHU in Alternative 2.
- The annual O&M cost recognizes that there is less maintenance on the one AHU (Alternative 2) as opposed to the six unit heaters (Alternative 1).
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 is the Best Value Alternative. **As such, Alternative 2 Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit is the recommended alternative.** Since Alternative 1 consists of in-kind replacement of the unit heaters and ventilation equipment, these units will be included in the SRP, not a CIP project.

Table 6-13. Alternative Evaluation for Replace Chemical Room Unit Heaters and Ventilation System (Project BC-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Chemical Room Unit Heaters and Ventilation System In-Kind	Health and Safety	3	2.78	\$ 73,400	\$ 5,760	\$ 194,876	\$ 70,015	Best Value Alternative
	<i>Definition:</i>	Replace unit heaters in Chemical Room in-kind, with material compatible with corrosive atmosphere	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Multiple units require increased maintenance	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement of unit heaters 2 times during 20-year period. O&M assumes annual maintenance of 6 hrs per unit.	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Chemical Room Unit Heaters and Ventilation System with Air Handling Unit	Health and Safety	4	3.60	\$ 236,000	\$ 2,400	\$ 286,615	\$ 79,615	
	<i>Definition:</i>	Replace unit heaters in Chemical Room with a make-up air unit outside Room at ground level	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier access for maintenance, fewer units to maintain, protected from corrosive atmosphere	Capacity Enhancement	3						
	<i>Disadv.:</i>	Tight site constraints for MAU	Component Performance	4						
	<i>Comments:</i>	O&M assumes annual maintenance of 20 hrs for AHU.	O&M Ease	4						

Headworks Building Electric Unit Heaters. The Trane UHXA unit heaters in the Headworks Building have an aluminum-finned tubular steel heat exchanger which is directly exposed to the air stream in the Headworks Building when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating which has passed the ASTM B117 salt-spray test. Indeeco makes such a unit, which has been installed in other CSO facilities. Based on the information presented here, new unit heaters will not be a capital improvement project; rather they will be replaced as part of the SRP.

6.2.6 Electrical

6.2.6.1 Description of Existing System

The Baby Creek facility's electrical system consists of a double-ended unit substation with dual (redundant) utility feeds, primary metering and DTE Energy indoor dry type transformers. The substation has a tie-breaker and automatic source transfer controls. Circuit breakers in the substation then feed four motor control centers (MCCs). The MCCs then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Because of the redundant electrical feed, this facility does not have an emergency generator. Table 6-14 provides a summary of the major electrical equipment for this facility.

Table 6-14. Major Electrical Equipment at Baby Creek

Location	Major Electrical Equipment	Description
Electrical Room 1	Double-ended unit substation	2,000 kVA, 24 kV-480/277 V, 3 Phase
Electrical Room 1	MCC-1	1,200 A, 480/277 V, 3 Phase
Electrical Room 1	MCC-2	1,200 A, 480/277 V, 3 Phase
Electrical Room 2	MCC-3	800 A, 480/277 V, 3 Phase
Electrical Room 2	MCC-4	800 A, 480/277 V, 3 Phase

Note:

kVA= kilovolt-ampere(s)

6.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for less safe working conditions. These lighting needs are in addition to the recent LED lighting project. This issue is further described in the next section.

6.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project BC-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating bypass gates at night and when accessing area downstream of screens.

2) **Alternative 2: Electrical Improvements.** Add Lighting and Exterior Power Receptacles at the following locations (and shown on the electrical drawings - Figure BC-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):

- Downstream of mixers – Add the required amount of ceiling and wall mounted LED lighting fixtures to provide sufficient lighting for O&M activities.
- Light pole by bypass gates - Add light pole and associated LED lighting fixture at the facility's bypass gates.
- Exterior power receptacles are needed about every 75 ft on the front and back wall of the facility to assist in the maintenance and operations of the facility. Receptacles should be accessible from ground level.

The alternative evaluation is presented in Table 6-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$38,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 6-15. Alternative Evaluation for Electrical Improvements (Project BC-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating bypass gates at night and when accessing area downstream of screens.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 133,000	\$ -	\$ 133,000	\$ 38,000	Not Applicable
	<i>Definition:</i>	Add additional lighting and receptacles at identified locations	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Minor increased maintenance and energy usage with increased number of lights.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

6.2.7 I&C

6.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2005 under PC-748. The Ovation system was designed having two separate control systems – one for the CSO Facility and one for the Sampling Building. The CSO Facility's control system has the capability to control and monitor both systems; whereas the Sampling Building control system only monitors the outfall and controls the Miller gates. In 2015 under Job Order JB -173 the CSO Ovation system controllers and software were upgraded to O.V.3.5.0.

The existing CSO Facility Ovation system is composed of a typical Ovation control network with primary and backup network switches. The switches are connected to the GLWA AT&T wide area network via the system's router. It has three operator workstation stations, plus a database server. A redundant pair of Ovation controllers provides the station with controls and I/O capabilities. A 10 kilovolt-amperes (kVA) Liebert uninterruptible power supply is used to provide constant power to the network equipment and workstations. The network connections inside the facility are via copper Ethernet cables. The controller's connections are dual-homed, which means each controller has one connection to each of the network switches. Should one network fail, the backup, redundant network is available to provide station monitoring and control. The current system is equipped with a backup radio system to communicate critical monitoring points back to the System Control Center on wide area network failure.

The Sample Building's Ovation system consists of Ovation local I/O points, a controller, and a HMI that can only perform local control. Communications are via telephone line with radio backup to the CSO Facility. The local control panel is in poor condition and should be replaced in the near future due to reoccurring maintenance issues. The Sampling Building local control system was not updated in 2015 and is still operating on the old O.V.3.1. platform.

Flow and Level Sensors: Table 6-16 summarizes the level sensors and flow meters at the Baby Creek CSO facility used to monitor flows through the treatment system, chemical feed, and chemical storage.

Table 6-16. Summary of Flow Meters and Level Sensors at Baby Creek CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent (Elmer Ternes, East Barrel, West Barrel)	3	Transit-Time (AccuSonic)
CSO Level Sensors		
Influent (Elmer Ternes)	1	Ultrasonic
	1	Radar (Backup)
Influent (East Channel)	1	Ultrasonic
	1	Radar (Backup)
Influent (West Channel)	1	Ultrasonic
	1	Radar (Backup)
Screening Area (Upstream and downstream of screens)	6	Ultrasonic
	6	Radar (Backup)
Effluent Channel	1	Ultrasonic
	1	Radar (Backup)

Area	Quantity	Instrument Type
<i>Chemical System Flow Meters</i>		
Chemical Feed	2	Magnetic
Carrier Water	1	Magnetic
Service Water	1	Magnetic
<i>Chemical Storage Level Sensors</i>		
Chemical Storage Tanks	4	Ultrasonic

6.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Address influent screen VFD failures
- Evaluate level sensors to determine redundancy and identify level sensors that could potentially be removed
- Need for additional flow meters and level sensors to improve monitoring and control of facility flows during wet weather and dewatering phases and level monitoring of tank levels at the Chemical Fill Station
- Need for process cameras at select locations to improve monitoring of facility during wet weather operation
- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Update Ovation control system to the latest version and increased monitoring capabilities
- There is a lack of full monitoring and control of CSO facility from the Effluent Sample Building
- The facility bypass gates require manual operation. During large storm events, this takes on operator away from other activities. Providing remote control of these gates is an ongoing project. As such, it is not included in the capital improvement projects for CS-299.

6.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project BC-I&C-1). Due to the relatively small nature of some of the I&C-related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation control system upgrade and the full monitoring and control capability of the entire facility from the Effluent Sample Building, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) Alternative 1: Do Nothing/Replace In-Kind.

- Replace screen VFDs in-kind or leave VFDs in bypass mode
- Leave redundant level sensors in place

2) **Alternative 2: I&C Improvements** including,

- Address influent screen VFD failures
- Remove redundant level sensors
- Provide additional flow meters and level sensor
- Provide process cameras at select locations
- Provide local remote control for screens

Each of the I&C-related improvements listed above is described further in the following paragraphs:

Address influent screen VFD failures. Operations staff indicated the VFDs running the influent screens are subject to regular failures. The failures occur intermittently and cannot always be reset from the VFD. Operators have the option of bypassing the VFD to operate the screens, but without the ability to control the speed. It should be noted that, the screens operate at 100 percent speed constantly.

A short-term, temporary solution to bypass the VFDs after a fault is available. Each of the influent screens is equipped with a bypass contactor separate from the VFD. A selector switch on the front of the influent screen control panel is used to select the “bypass” mode. While operating in bypass mode, the influent screens will run in the forward direction at full speed. The reverse jog pushbutton located in a control station on the process floor near each influent screen, which is intended to momentarily reverse the screens in the event of a jam, will not function while the screens are in bypass mode. The VFD is used to provide the reversing feature and is not available while being bypassed. Operations has indicated the reverse jog feature is never used, so operating the influent screens in bypass mode is an acceptable, temporary option.

For a long-term solution, the influent screen manufacturer should be consulted to determine the path forward and if VFDs are necessary. If the influent screens do not require VFDs to operate, the VFDs should be removed and replaced with constant speed starters, similar to operation while in bypass mode. A second, reversing contactor should be included and interfaced with the reverse jog pushbutton located at the influent screens. Internal wiring modifications and as-built record drawings should be included. If the VFDs are necessary for long-term operation, the VFDs should be replaced with modern units to avoid the intermittent VFD failures.

Remove redundant level sensors. During the January 2020 Facilities Assessment meetings with O&M staff, GLWA requested that Jacobs investigate existing level sensors at all facilities to determine where there was redundancy and identify level sensors that could potentially be removed to minimize the number of instruments. The main focus of this investigation was the level sensors throughout the CSO treatment process.

There are two sets of level sensors in the influent channel at Baby Creek. Each set contains a primary ultrasonic and backup radar level sensor. One set is for the southern end of the channel (near Screen 2) where the influent weir is at El. 91 ft and the other is at the northern end (near Screen 11) where the influent channel is at El. 92 ft. Figure 6-4 shows the locations of these sensors. Review of the historical Ovation data for a recent six-month period shows that these two sets of level sensors have nearly identical readings, and as such, one set could potentially be removed. If removed, this would provide one ultrasonic level sensor as the primary sensor and one radar sensor as the backup for the influent channel.

There are also several redundant level sensors immediately upstream and downstream of the screens. Figure 6-4 highlights the locations of these level sensors in the Headworks. The original intent of these sensors, as depicted in the piping and instrumentation diagrams, was to provide the differential level readings for banks of screens to indicate when the screen should turn on and the speed of the screen. GLWA (and previously Detroit Water and Sewerage Department) have not used this feature since the major screen blinding/failure issues shortly after facility startup. Currently, the screens are

turned on at high speed when needed and then turned off after the wet weather event. Also, the jog feature is reportedly not used by operations staff. The removal of these differential level sensors (in accordance with Figure 6-4) would prevent the jogging feature of the screen and the speed adjustment, both of which are not used.

Provide additional flow meters and level sensors. Operations staff requested additional flow or level monitoring at the following locations:

- **Outfall Level Sensor:** GLWA requested a level sensor at the outfall. Consistent with the level measurement technology in Section 5.4.3, a radar level instrument is recommended.
- **Effluent Conduit Flowmeter:** The flowmeter should not be an Accusonic model but should be a laser-based flowmeter such as a TieNet 360 LaserFlow Velocity meter.
- **Bypass Conduit Flowmeter:** It should be noted that Jacobs performed a more detailed assessment of a laser-based flowmeter (TieNiet360 LaserFlow Velocity meter) for this location. Although the cost of the flow meter itself is significantly less than that of an Accusonic meter, the total project cost was greater than expected due to the significant cost for the structure above the conduit to provide adequate room for proper flow measurement. This flow meter is not included in the cost estimate.
- **Chemical Fill Station:** Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Provide local remote control for screens. Provide local control for the screens in accordance with Section 5.4.9.

The alternative evaluation is presented in Table 6-17. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 includes VFD replacement for all screens and level sensors.
- The capital cost for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 include estimated annual maintenance of the valve control network. The O&M costs for Alternative 2 include estimated annual maintenance costs for the additional instrumentation provided.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative because the NPV/Benefit cost of Alternative 1 is approximately \$148,000 lower than that of Alternative 2. The total benefit score for Alternative 2, however, is 0.5 higher than Alternative 1 due to improved component performance and ease of O&M. **Since Alternative 2 provides increased performance and ease of O&M, it is the recommended alternative.** Due to the high NPV/benefit cost, however, it is not necessarily a high priority project if there are budget constraints.

Figure 6-4. Baby Creek CSO Facility Level Sensor Identification

Table 6-17. Alternative Evaluation for I&C Improvements (Project BC-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.78	\$ 347,600	\$ 4,500	\$ 442,503	\$ 158,983	Best Value Alternative
	<i>Definition:</i>	Replace screen VFDs and level sensors in-kind.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	O&M assumes annual maintenance of 5 hrs for level sensors; \$10,000 per year for valve network maintenance.	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 766,000	\$ 12,000	\$ 1,019,076	\$ 307,259	
	<i>Definition:</i>	Address VFD screen failures; removal of redundant level sensors; provide additional flow meters & sensors; provide process cameras; provide local control for screens	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	O&M assumes annual maintenance of 5 hrs for level sensors; 20 hrs for flow meter; 10 hrs for cameras.	O&M Ease	4						

Control System Upgrade (Project BC-I&C-2). This project updates the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2. A full list of control system upgrades at the Baby Creek CSO facility is included in the following bullets:

- Update Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.
- Replace the Sampling Building local control panel
- Update the Sample Building Ovation system to provide full control of the facility from the Sampling Building

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 6-18 provides the summary of the Control System Upgrade, which is the recommended alternative. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title.

Table 6-18. Alternative Evaluation for Control System Upgrade (Project BC-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,337,000	\$ -	\$ 1,337,000	\$ 445,667	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Replace Sample Building local control panel. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Updates the control system to allow for enhanced performance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

6.2.8 Site

6.2.8.1 Description of Existing Site

The Baby Creek Control/Headworks Building site includes a 20-ft wide concrete paved access road off of Dix Rd on the west side of the facility. A concrete paved parking area is located on the northwest side of the Control Building. Site pavement on both sides of the building consists of 10- in. concrete and 6- in. aggregate base. Site runoff is collected by a storm sewer network in the parking areas and in grassy areas on the perimeter of the site. Then the flow is conveyed to the combined sewers onsite. Site security around the perimeter of the facility is provided by 8-foot-high ornamental fencing. Access to the facility is controlled by a sliding security gate located at the northwest corner of the Control Building.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's geographic information system (GIS). Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, Global Positioning System (GPS) date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this section.

6.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following sections.

- The fence is damaged in some locations due to lawn mower strikes.
- The existing access hatch to the Baby Creek sewer requires a crane to remove concrete planks. This is being addressed in an ongoing "Baby Creek Outfall Improvements" project (CIP 277001).
- An additional access point is needed downstream of the Screens 1-4.
- The stop logs are currently stored out-of-doors at the facility. The stop logs rubber seals are damaged by sunlight and, subsequently, are not effective when needed for flow isolation.
- The existing entrance gate is a 24-foot-wide cantilever sliding ornamental gate. The gate has experienced frequent electrical issues and has remained out of service for extended periods of time awaiting repair. During periods when the gate is out of service, it remains in an open position, which is a security concern particularly during hours of the day when there are fewer staff at the site. This was addressed in late 2020 under the GLWA-Contract No. 2001372 – Task 25 "Baby Creek Entrance Gate Repairs & Improvement" project.
- The following needs are generally PM items intended to ensure that the site features and utilities are serviceable throughout their expected service lives. These needs are listed in the following bullets and are not included in the capital improvement projects for CS-299. It is recommended that these issues be addressed by a GLWA-wide facilities maintenance contract. If not addressed.
 - Seal concrete pavement joints to prevent water infiltration

- Caulk expansion joint at the base of Control and Headworks Buildings between the walls/sidewalks along the north, south and west sides of the buildings
- Repair cracks in access drive and sidewalks

6.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Repair Security Fencing and Add Concrete Maintenance Strip (Project BC-SITE-1). The existing security fencing consists of 8-foot- tall powder coated aluminum fencing with 1- in. square fencing pickets. The total length of fencing is approximately 1,920 ft. The bottom of the fencing panels have experienced damage at several locations due to lawn mower strikes (example of damaged fencing shown in Figure 6-5). The impacts have left the bottom 6 to 8 in. of the pickets and posts severely bent or broken off. The fence is about 14 years old and, aside from the damaged pickets, remains in good condition. The damage sustained by the fencing does not currently impact security; however, because several fence posts have been damaged the fencing integrity in those areas has been compromised. There are two alternatives for addressing this issue. These alternatives include:

- 1) **Alternative 1: Do Nothing.** Repair bottom of fence, as necessary.
- 2) **Alternative 2: Repair Security Fencing and Add Concrete Maintenance Strip.** this alternative replaces the damaged fencing panels and posts. To avoid future damage by lawn mowing equipment, it is recommended that a maintenance strip be established 2 ft from each side of the fence line to avoid future strikes. The concrete maintenance strips beneath the fencing appear to have worked well at other sites.

Figure 6-5. Example of Damaged Fencing at Baby Creek CSO Facility

The alternative evaluation for these alternatives is presented in Table 6-19. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to the limited extent of damage to the fence (i.e., only at the bottom), it is recommended that the fence be repaired, as necessary, and replaced when it has reached the end of its useful life. **As such, Alternative 1 is the recommended alternative.**

Table 6-19. Alternative Evaluation for Security Fencing (Project BC-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Replace fence in-kind at the end of useful life	Water Quality & Compliance	3

	<i>Comments:</i>	None	O&M Ease	3						

Stop Log Storage Shelter (Project BC-SITE-2). The stop logs are currently stored out-of-doors onsite at the Baby Creek CSO facility. The stop logs are equipped with compressible rubber seals that are susceptible to damage as a result of prolonged exposure to ultraviolet (UV) light. This results in their premature aging, impacting their ability to effectively prevent leakage when installed in the sewer stop log guides. The stop logs are currently stored in an area located between the Woodmere Pumping Station and the Baby Creek Headworks building, which has a footprint of approximately 60 ft by 20-ft. The stop logs are stored on grade and stacked next to each other. The stop logs rubber seals are damaged by sunlight and, subsequently are not effective and leak. There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing.** Continue to store stop logs outside.
- 2) **Alternative 2: New Stop Log Storage Shelter and Racks.** The purpose of a new storage shelter is to provide protection for existing isolation stop logs. The storage shelter must provide protection from UV light and exposure to the elements, but its design must also remain open enough to allow equipment to access and move the stop logs in and out of the shelter. Per discussions with GLWA, the new shelter is to be located in the same general area as the existing storage area.

There are two potential styles of structure that could be used for a stop log shelter: a pavilion style pitched roofed structure or a semi-permanent canopy style structure. The pavilion style structure is generally a steel truss and post framed structure with a steel panel roof but generally without permanent sidewalls. The canopy structure can be a steel or aluminum framed structure with a heavy-duty PVC or polyethylene fabric cover that covers the entire framing structure to ground level. Either structure can be designed to meet Michigan Building Code requirements for snow and wind loads. The canopy style structure would provide additional UV protection with covered sidewalls extending to grade and is recommended for the storage of the stop logs. In addition, this option is less permanent than a pavilion structure, in the event that this structure might need to be moved around within the property. See Figure BC-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B, for the location of the proposed stop logs storage shelter. The figure also shows conceptual photos of what this type of semi-permanent low-tech structure would look like.

To avoid storage of stop logs directly on grade, it is also recommended that the shelter be placed on a concrete pad and the stop logs be stored in racks. These items are included in the cost estimate in BC-SITE-2 in Volume 6 – Appendices, Appendix C under this project title.

In addition, GLWA also requested that a new access hatch be provided to allow access for the area downstream of Screens 1 to 4. This hatch will be located outside of the facility near the existing concrete pavement above the channel (Figure BC-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B), provides the approximate location. Soils will be excavated above the existing roof near the outer channel wall to allow installation of a new 4-foot by 4-foot accessway and fall-restraint type ladder. The roof slab will be sawcut, and a precast utility vault section set and affixed. This opening size is required to accommodate the ladder assembly to the surface, clear space for personnel entering/exiting the lower facility and adequate space for personnel extraction connections to move freely between the lower facility and surface. A locking traffic-rated hatch (HS-20) is recommended. The existing pavement section will be extended to this new hatch location to provide a clean, paved working surface for topside activities while manned-entry into the lower area is underway.

The alternative evaluation for these alternatives is presented in Table 6-20. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – New Stop Log Storage Shelter and Racks has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and improved O&M provided by protecting the rubber seals on the stop logs. The NPV/Benefit cost for Alternative 2 is \$145,000, which is a relatively high cost compared to other projects

recommended in this assessment. Based on this information, **Alternative 2 - New Stop Log Storage Shelter and Racks** is recommended; however, it should be a relatively lower priority than other projects.

Table 6-20. Alternative Evaluation for Stop Log Storage (Project BC-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

6.2.9 Architectural

6.2.9.1 Description of Existing Facilities

The Baby Creek CSO facility consists of one main building with rooms for the process systems (screening and chemical feed/storage), odor control, utility support (electrical and mechanical), control room and other miscellaneous rooms. The facility also includes a small, off-site effluent sample building about a mile from the main building.

6.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. The facility has a shingled roof. About one-third of the roof surface was replaced in 2017. A recent (2020) assessment by a roofing contractor (Schreiber) indicated that the remaining two-thirds was in “poor” condition and there have been leaks into the Electrical Room during recent rain events. GLWA requested that Jacobs perform a cost comparison of replacing the shingled roof with a metal roof.

Jacobs reviewed the results of the roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows a lower life-cycle cost for shingled roof, Jacobs recommended replacement of two-thirds of the roof with shingles. The analysis is presented in Table 6-21. Subsequently, GLWA requested that drawings and a roof replacement specification be developed to use in contracting for roof replacement. This project should be completed in 2021. As such, it is not included in this report as a future capital project. The SRP model was manually adjusted to recognize the improvement of this ongoing project.

Table 6-21. 60-Year Life-Cycle Cost Evaluation of Shingled vs. Metal Roof for Baby Creek Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$649,000	\$2,163,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life-Cycle Cost (NPV) Discounted at 2.4%	\$1,762,000	\$2,163,000

^a Based on 43,250 ft² roof area; \$15/ ft² for shingle roof and \$50/ ft² for metal roof.

Note:

ft² = square feet

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities under CS-299. Jacobs used the architectural-related information in NTH’s Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the aboveground buildings as a starting point and included additional items, as observed during the assessments conducted under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that that the floor coating in the Chemical Room had been consumed by sodium hypochlorite spills and the floor was flat and did not slope toward the sump.

6.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (BC-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessment. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Repair and replace cracked guardrail member; make unstable base connections for FRP guardrail more rigid
 - Address door and door frame corrosion issues, and door hardware issues for various doors
 - Clean localized rusted areas of structural steel surface and recoat localized steel areas in Headworks
 - Clean rusted areas of steel bollards and recoat all exterior bollards
 - Remove and replace, in kind, disbonded tile and underlayment from concrete floor
 - Repair/ patch finish material and repaint ceiling of entryway exterior canopy
 - Clean corrosion in steel base/ steel column supporting the entryway exterior canopy and repaint

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure BC-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 6-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the need to prevent more costly damage in the future from not addressing these issues, **Alternative 2 - Architectural Rehabilitation is the recommended alternative.**

Table 6-22. Alternative Evaluation for Architectural Rehabilitation (Project BC-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable

	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 596,000	\$ -	\$ 596,000	\$ 192,258	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

Slope Chemical Room Floors and Add Coating (Project BC-ARCH-2). GLWA requested Jacobs evaluate modifying the floor slope in the Chemical Room to drain to the sump. There are three alternatives evaluated:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Corrosion-Resistant Floor Coating in Chemical Room** (on existing flat floor). This alternative only provides a floor coating which is currently being considered to address an immediate need for floor protection. Jacobs has successfully used the following highly chemical-resistant coating systems in sodium hypochlorite containment areas:
 - Surface Preparation: Meet requirements of Society for Protective Coating SP 13 and coating manufacturer's instructions.
 - Primer: 1 coat of the manufacturer's recommended concrete primer.
 - Filler/Surfacer: 1 coat as required to fill voids of trowel grade filler and surfacer designed for vinyl ester coating.
 - Finish: 2 coats of vinyl ester coating resistant to containment service of 12.5 percent sodium hypochlorite solution. Provide slip resistant surface on floors.
- 3) **Alternative 3: Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room.** This alternative includes sloping the floor before adding the coating described in Alternative 2. Sloping the floor would be accomplished by grouting over the existing floor. Grouting should be coordinated with the chemical feed system replacement project, if possible. Coating of the floor should be done after increasing the floor slope.

The alternative evaluation is presented in Table 6-23. The capital costs for Alternative 2 and 3 are included in Volume 6 – Appendices, Appendix C under this project title.

As shown in Table 6-23, Alternative 2 has a Total Benefit score about 1.0 higher than Alternative 1 because of the chemical resistant coating protecting the concrete floor. Alternative 3 has a Total Benefit score about 1.2 higher than Alternative 2 based on the improved health and safety, component performance, and ease of O&M with the chemical resistant coating and the sloped floor. Coating the floor is necessary to protect the concrete floor over the life of the facility. Examination of the NPV/benefit costs for the alternatives that provide a coating (Alternatives 2 and 3) shows that Alternative 3 has the lowest cost. **As such, Alternative 3 - Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room is the recommended alternative.**

This project should be scheduled with future improvements to the chemical feed system. If these improvements do not occur within the next two to three years, consideration should be given to coating the existing floor to preserve the condition of the concrete.

Table 6-23. Alternative Evaluation for Slope Chemical Room Floors and Add Coating (Project BC-ARCH-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

6.2.10 Safety

6.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

6.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 6-24. The capital improvement project to address these issues is included in the table.

Table 6-24. Identification of Capital Improvements for Safety Issues

Location	Description	Proposed Corrective Action	Capital Improvement Project
Sample Room	Door needs illuminated exit sign	Add exit sign	Exit Sign Improvements ^a
Mechanical Room	No illuminated exit sign on exterior door	Add exit sign	Exit Sign Improvements ^a
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project BC-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

6.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section.

Safety Improvements (Project BC-SAFE-1). This project should address the safety issues identified above. These issues include:

- Fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 6-25 shows the one alternative.

Table 6-25. Alternative Evaluation for Safety Improvements (Project BC-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 236,000	\$ -	\$ 236,000	\$ 78,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection and eye washes.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

6.2.11 Supporting Infrastructure

6.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

6.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Inefficient mixer removal system – includes evaluation of monorail vs. gantry cranes with electric hoist and electric trolley to replace existing hand chain hoist.
- Address inability of overhead crane to access dewatering pump.
- Address high iron sediment concentration in potable water lines. GLWA has experienced high iron concentrations in incoming potable water to the facility. In August 2020, flushing of the incoming 8-in. water mains servicing the facility conducted under CS-299 in an effort to remove the cause of the rust colored water within the facility. A few weeks after the flushing exercise, the operators reported rust colored water again. Based on the results of the flushing samples and the return of the rust color, the following recommendation were made to minimize the iron in these lines:
 - For the eye wash in the Chemical Room, it is recommended to install an automatic solenoid valve on a timer to routinely flush this line for a set period of time each day. The operators could do this over a few consecutive days to find out how long it takes to flush the line before the iron dissipates. If it takes a long time and there is a large amount water on the floor, there should be consideration to providing a permanent drain to the sump. However, the results seem to indicate the iron color may dissipate quickly, especially if it is flushed routinely.
 - For the kitchen, a point of use device could be installed specifically designed for iron removal.

These projects could be done by GLWA maintenance and are not included in the capital improvements.

6.2.11.3 Discussion and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Improve Mixer Removal System (Project BC-SUPP-1). The overhead bridge crane was not designed with adequate side-to-side reach for removal and installation of the induction mixers. Currently, portable A-frame gantry cranes with hand chain hoists are used for this purpose. An improved mechanism for removing and installing the induction mixers is desired.

Three alternatives are identified in the following list:

- 1) **Alternative 1: Do Nothing.** Continue to use gantry cranes with hand chain hoists.
- 2) **Alternative 2: Monorail System.** Provide two parallel monorails centered over the two pairs of induction mixers in each mixing zone. The monorails would run the length of the building (or shorter monorails could be provided serving one or more of the mixing zones). Two continuous monorails the

length of the building were assumed for estimating cost. One ¼ ton electric hoist with manual trolley on each of the two parallel monorails was assumed for estimating cost.

- 3) **Alternative 3: A-Frame Portable Gantry Cranes with Electric Hoists.** Provide two new portable A-frame gantry cranes with a ¼ ton electric hoist and trolley on each.

The alternative evaluation is presented in Table 6-26. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. The table shows that Alternative 3: A-Frame Portable Gantry Cranes with Electric Hoists provides a Total Benefit score of 1.0 higher than the Do Nothing alternative because of improvement safety and ease of O&M. The table also shows that the NPV/Benefit cost is more reasonable than the Alternative 2 – Monorail System. **As such, Alternative 3 is the recommended alternative.**

Table 6-26. Alternative Evaluation for Improve Mixer Removal System (Project BC-SUPP-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use gantry cranes with hand chain hoists	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Raising mixer out of channel for inspection is more difficult and less safe.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Monorail System	Health and Safety	5	4.00	\$ 998,000	\$ -	\$ 998,000	\$ 249,500	Not Applicable
	<i>Definition:</i>	Provide two parallel monorails centered over the two pairs of induction mixers in each mixing zone. One ¼ ton electric hoist with manual trolley on each of the two parallel monorails.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Raising mixer out of channel is easier and safer.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Highest cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						
3	<i>Alt. Name:</i>	A-Frame Portable Gantry Cranes with Electric Hoists	Health and Safety	4	3.50	\$ 266,000	\$ -	\$ 266,000	\$ 76,000	Not Applicable
	<i>Definition:</i>	Provide two new portable A-frame gantry cranes with a ¼ ton electric hoist and trolley on each.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Raising mixer out of channel is easier and safer than existing operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not as easy as monorail system.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Overhead Crane Access for Dewatering Pump (Project BC-SUPP-2). O&M staff indicate that the existing building's overhead crane is unable to remove the dewatering pump. This is because the overhead crane travel does not reach the mid-point of the rails for the submersible dewatering pump. In order to use the overhead crane, the hook must be able to pull the dewatering pump straight up the rails, or the pump will not be able to be removed. Figure 6-6 illustrates this issue.

Two alternatives are identified in the following list:

- 1) **Alternative 1: Do Nothing.** Continue to use gantry crane. The gantry crane does not fit well into the space, making it difficult to remove the pump.
- 2) **Alternative 2: Add Trolley to Overhead Crane:** Jacobs contacted Crane Technologies, the original crane supplier for solutions to this issue. They recommended a 2-ton capacity electric chain hoist with motorized trolley. The hoist would be powered from a festoon track system that would have to be installed on the crane bridge. The hoist would be controlled from either a dedicated hard wire pendent, (which would have the concern for that pendent hanging down when the crane bridge is traveling down the runway), or from a dedicated radio control device, which would eliminate the corded pendent. The radio control system is recommended. The system would be explosion-proof rated.

Figure 6-6. Overhead Crane Issue

The alternative evaluation is presented in Table 6-27. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. The table shows Alternative 2 has a Total Benefit score of 1.5 higher than the Do Nothing Alternative because of improved safety and ease of O&M. The NPV/Benefit cost for Alternative 2 is about \$22,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety and O&M with this alternative, Alternative 2 – Add Trolley to Overhead Crane is the recommended alternative.**

Table 6-27. Alternative Evaluation for Overhead Crane Access for Dewatering Pump (Project BC-SUPP- 2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to utilize gantry crane to remove dewatering pump	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Extremely tight site conditions make positioning the gantry crane difficult, and potentially unsafe.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Add Trolley to Overhead Crane	Health and Safety	5	4.00	\$ 90,000	\$ -	\$ 90,000	\$ 22,500	Not Applicable
	<i>Definition:</i>	Add a 2-ton capacity electric chain hoist with motorized trolley	Water Quality & Compliance	3						
	<i>Adv.:</i>	Simplified pump removal and install	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

6.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Baby Creek CSO facility, Table 6-28 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 6-28, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 6-28. Listing of Asset Condition Assessments for Baby Creek Facility

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The five Roof Ventilators (non-motorized) on the roof were not accessible

^c The two Make Air Units are duplicates of the HV-1 and HV-2 Air Handling Units. These MAUs should be deleted in the future.

^d The two post-screening pumps are not in service and were not assessed.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Baby Creek Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

6.3 Capital Planning for Baby Creek CSO Facility

6.3.1 Summary of Capital Improvement Plan Projects

Table 6-29 provides a summary of the recommended CIP projects and associated capital costs for the Baby Creek CSO facility based on the alternative evaluations conducted for this facility.

Table 6-29. Summary of Recommended Projects at Baby Creek CSO Facility

Project No.	Alternative	Description	Total Project Cost
BC-DIS-1	3	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 1,237,000
BC-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 201,000
BC-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
BC-FD-1 ^a	2	Flushing System in Influent Area	\$ 787,000
BC-ELEC-1	2	Electrical Improvements	\$ 133,000
BC-I&C-1	2	I&C Improvements	\$ 766,000
BC-I&C-2	1	Control System Upgrade	\$ 1,337,000
BC-SITE-2	2	New Stop Log Storage Shelter and Racks	\$ 497,000
BC-ARCH-1	2	Architectural Rehabilitation	\$ 596,000
BC-ARCH-2	3	Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room	\$ 338,000
BC-SAFE-1	1	Safety Improvements	\$ 236,000
BC-SUPP-1	3	A-Frame Portable Gantry Cranes with Electric Hoists	\$ 266,000
BC-SUPP-2	2	Add Trolley to Overhead Crane	\$ 90,000

Note:

^a Although this project is not recommended at this time, it is included in the CIP to be reconsidered based on experience gained from contractor cleaning of the influent channel.

6.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 6-30. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 6-30. Capital Improvement Plan Projects for Baby Creek CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
BC-1 Disinfection System Improvements	\$1,785,000	2033 <i>Timing based on existing asset condition</i>	BC-DIS-1	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 1,246,000
			BC-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 201,000
			BC-ARCH-2	Provide Corrosion-Resistant Floor Coating and Slope Floor in Chemical Room	\$ 338,000
BC-2 Influent Flushing System^a	\$ 787,000	2036 <i>Project to be re-evaluated after another cleaning cycle of the influent area</i>	BC-FD-1	Flushing System in Influent Area	\$ 787,000
BC-3 Facility-Wide Electrical and I&C Improvements	\$ 2,723,000	2025 <i>Timing based on asset condition</i>	BC-I&C-1	I&C Improvements	\$ 766,000
			BC-I&C-2	Control System Upgrade	\$ 1,337,000
			BC-ELEC-1	Electrical Improvements	\$ 133,000
BC-4 Facility-Wide Safety and Architectural Improvements	\$ 829,000	2023 <i>Project should be initiated as soon as possible</i>	BC-SAFE-1	Safety Improvements	\$ 229,000
			BC-ARCH-1	Architectural Improvements	\$ 600,000
BC-5 New Stop Log Storage Shelter	\$ 497,000	2030 <i>Timing based on best judgement</i>	BC-SITE-2	New Stop Log Storage Shelter and Racks	\$ 497,000
BC-10 Model Disinfection Performance	\$ 50,000	2021 <i>Timing based on potential for major maintenance cost reduction</i>	BC-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000

Note:

^a Although this project is not recommended at this time, it is included in the CIP to be reconsidered based on experience gained from contractor cleaning of the influent channel.

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 6-31 and Table 6-32 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 6-32 indicates that BC-DIS-1 project has two assets that need to be replaced immediately due to condition score of "5". These assets, however, have already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining 40 assets that are included in this project have an average condition score of 1.55 and an average replacement date of 2034 (See Table 6-31). This information was used to propose a scheduled construction completion date of 2033.

Table 6-31. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BC-DIS-1	40	1.35	1.55	2.43	21	2034	\$ 1,065,500
BC-DIS-3	29	1.29	1.24	2.08	10	2030	\$ 1,450,000
BC-HVAC-1	7	1.14	1.59	2.05	16	2032	\$ 39,801
BC-I&C-1	24	1.38	1.46	2.37	11	2031	\$ 329,307
BC-I&C-2	3	1.57	1.38	2.70	10	2030	\$ 803,097
BC-SAFE-1	2	1.71	1.29	2.82	10	2030	\$ 25,336
BC-SITE-1	1	1.29	1.33	2.14	20	2039	\$ 391,500

Table 6-32. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BC-DIS-1	2	1.29	5.00	4.50	10	2021	\$ 102,000
BC-DIS-3	3	1.29	5.00	4.50	10	2021	\$ 150,000
BC-HVAC-1	1	1.14	5.00	4.00	15	2023	\$ 4,800
BC-I&C-1	1	1.43	5.00	5.00	10	2021	\$ 18,300
BC-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -
BC-SAFE-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
BC-SITE-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

There are a number of recommended capital improvement projects presented in Table 6-29 that could be better delivered under capital outlay projects. These projects are listed in the following bullets:

- A-Frame Portable Gantry Cranes with Electric Hoists (BC-SUPP-1)
- Add Trolley to Overhead Crane (BC-SUPP-2)

For the CFD Modeling of Mixers (BC-DIS-3), it is ultimately recommended to include this project with similar modeling projects at the Conner Creek and Leib CSO Facilities. See Section 2 (Volume 1 – Project Introduction and Capital Improvement and Outlay Plans) for proposed bundling of this project.

6.3.3 20-Year Capital Outlay Plan

Table 6-33 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 6-33. 20-Year Capital Outlay Plan for Baby Creek CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 501,900	\$ 25,000	\$ -	\$ -	\$ 252,000	\$ -	\$ -	\$ 224,900	\$ -	\$ -	\$ -	\$ -	\$ -

Total	\$ 19,610,103	\$ 1,206,641	\$ 445,276	\$ 5,436,713	\$ 3,777,535	\$ 2,619,091	\$ 78,010	\$ 1,251,682	\$ 2,592,566	\$ 994,379	\$ 514,290	\$ 666,503	\$ 27,416

Notes:

Explanation of large capital outlays in first two years:

- Screening System: Screen No. 1 was out of service at the time of the Condition Assessment for major repair and received a score of 5. It has since been put back into service and could be reassessed.
- Disinfection System: Three mixers (\$50,000 each; \$150,000 total) were missing/out of service at the time of the Condition Assessment. Also, two chemical feed pumps (\$51,000 each; \$102,000 total) were missing.
- HVAC System: The Air Handling Unit (HV-2) was not operational two different times during the Condition Assessment. Unit was new in early 2020. It has since been fixed. Also, there was one unit heater in the Chemical Room that was out of service.

7. Belle Isle CSO Control Facility

7.1 Existing Facility Description and Future Capacity Considerations

7.1.1 General Facility Description

The Belle Isle CSO Facility is an RTB with 300,000 gallons of storage and a treatment capacity of 33 cfs. It was constructed in 2007. The facility consists of a headworks, chemical room, odor control room, electrical room, mechanical room, control room, sample room, and restrooms. The facility also includes an adjoining Belle Isle Pump Station, which is not included in this facility assessment.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

7.1.2 Future Capacity Considerations

Jacobs recommends an evaluation of sewer separation on Belle Isle be conducted in an effort to reduce or eliminate treatment of wet weather flows.

A review of the Belle Isle Basis of Design shows that sewer separation was considered as an alternative to constructing a regional treatment basin (RTB). In 1998, there was a concern that stormwater treatment at a single location may be required. As such, 8,100 ft of storm sewer piping was included in the cost comparison for the sewer separation alternative. Given the current movement toward green infrastructure, stormwater treatment does not appear to be a concern, particularly for a natural location such as Belle Isle.

A study of current wet weather flows and inflow and infiltration for the Belle Isle sewer system should be conducted to determine whether sewer separation and infiltration and inflow (I&I) control could reduce wet weather flows sufficiently to completely eliminate the need for the RTB (i.e., screening, disinfection, storage, and odor control). If I&I cannot be reduced enough to eliminate the need for the RTB, flows should be reduced enough so that the facility could operate as a complete capture facility. This would eliminate the need for disinfection, screening (potentially), and operator involvement during storm events.

7.2 Facility Assessment

7.2.1 Screening

7.2.1.1 Description of Existing System

The Belle Isle CSO Facility has two perforated horizontal band screens that were installed in 2007. Screenings that are captured by the screens are pumped by the Screenings Recirculation Pumps back to the Belle Isle Pump Station, where they are conveyed by the sanitary pumps to the Detroit River Interceptor (DRI), and ultimately to the WRRF.

Table 7-1 provides an overview of the existing screening system at Belle Isle CSO facility.

Table 7-1. Overview of Existing Screening System at Belle Isle CSO Facility

Parameter	Value
Treatment Capacity (cfs)	33
Number of Screens	2

Parameter	Value
Manufacturer	JWC Environmental
Screen Type	Horizontal Band Screen
Opening Size	6-mm perforation
Depth or Length / Width	7 ft 8 in. / 2 ft 8 in.
Screen Cleaning	Brush and high-pressure spray
Screening Removal	Screenings pumped to Pumping Station and conveyed to DRI and to WRRF

Note:

in. = inch(es)

7.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- Existing band screens are difficult to maintain due to tight site conditions

7.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screen Replacement (Project BLI-SCR-1). The existing band screens perform well but maintenance is difficult due to their location under the grating and tight site conditions. The existing JWC Environmental horizontal band screens have 6-millimeter (mm) perforations. There are two alternatives:

- Alternative 1: Replace Existing Band Screens In-Kind.** This alternative would generally replace the existing band screens in-kind.
- Alternative 2: Replace Existing Screens with Fine Bar Screens.** A vertical fine bar screen was evaluated as a replacement. A vertical screen will provide adequate screening while being much more accessible for maintenance. Duperon's FlexRake FPFS-F fine bar screen was used as a representative screen and has 0.25- in. (approximately 6 mm) spacing. While a 6-mm perforation is finer than a 0.25-in. bar screen gap, both screens should provide equivalent screening. Michigan EGLE approval would be necessary for the 0.25-in. bar screen.

A vertical bar screen will require modifications to the existing channel. Currently, water enters the channel and flows up through the screen and over a weir as shown by the flow direction arrows on Figure 7-1. The existing screens extend approximately halfway across the channel. The vertical bar screen will extend across the full channel. Figure 7-2 shows the plan view of two vertical screening options. Option 1 positions the screen approximately halfway down the channel length while Option 2 positions the screen at the end of the channel where it leans up against the existing fiberglass screening retention baffle wall. A steel beam is needed to support the screen with both options. Duperon's screen may be completely vertical or at an angle of up to 45 degrees. The existing weir must be removed and filled in with concrete to prevent bypassing at high flows due to the long length of the existing weir. An opening downstream of the screen and cut into the concrete is necessary to convey the discharged flow. Option 2 requires an angled screen position and flow must discharge through a triangular opening.

Figure 7-2 also shows a 6-in. to 1-foot concrete bump out from the west wall extending the full channel depth for screen maintenance access. Positioning the screen at the end of the channel (Option 2) allows for screenings to discharge over the existing screening retention baffle wall into the screening wet well. Option 1 will require a screening sluice to convey screenings from the screens to the screening wet well. Figure 7-3 shows the sluice option. Headloss through the screen at the design flow of 16.5 cfs with 25 percent blinding is 0.04 in. Headloss through the existing JWC Environmental screen is unknown.

The alternative evaluation is presented in Table 7-2. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 1 were obtained from the screen replacement costs of the Scheduled Replacement Plan (SRP).
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C, under this project title.

This evaluation shows that Alternative 1 is the Best Value Alternative. Although maintenance would be easier for the proposed screen in Alternative 2, the difference in O&M costs were not calculated because the difference in capital costs is nearly \$1,000,000. Annualized over 30 years, this represents about \$51,000 (at 3 percent interest rate). It is unlikely the annual maintenance savings would be this high.

Because of the large difference in capital costs between the two alternatives, **Alternative 1 - Replace Existing Band Screens In-Kind is the recommended alternative**. As such, the replacement of these screens is not included in the CIP projects; rather it is included in the SRP.

Figure 7-2. Belle Isle Screening Channel Modifications

Figure 7-3. Illustration of a Screening Sluice for Belle Isle

Table 7-2. Alternative Evaluation for Screen Replacement (Project BLI-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Band Screens In-Kind	Health and Safety	3	2.78	\$ 978,000	\$ -	\$ 978,000	\$ 351,377	Best Value Alternative
	<i>Definition:</i>	Replace band screen in-kind	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system; has met permit	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance is difficult due to tight site conditions.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Existing Screens with Fine Bar Screens	Health and Safety	3	3.43	\$ 1,960,000	\$ -	\$ 1,960,000	\$ 570,874	
	<i>Definition:</i>	Modify screen channel to allow for different type of screen that will allow better access for maintenance	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Retrofit of facility	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

7.2.2 Disinfection

7.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two fiber-reinforced plastic (FRP) tanks, three diaphragm pumps, two disinfectant rapid mix zones, and four induction mixers. There are two screens and each discharge into two disinfectant rapid mix zones in series. There are two induction mixers, one per disinfectant rapid mix zone in series, consisting of one low level mixer and one high level mixer. The sodium hypochlorite pumps discharge to a common header that splits to the two mixing zones and splits again to each induction mixer in that zone. The Basis of Design Report does not discuss sodium hypochlorite flow splitting. Flow splitting is not metered and there does not appear to be any basis for throttling the valves to individual induction mixers to achieve equal flow splitting. Table 7-3 provides an overview of the existing disinfection system at Belle Isle CSO facility.

Table 7-3. Overview of Existing Disinfection System at Belle Isle CSO Facility

Parameter	Value
Treatment Capacity (cfs)	33
Design Feed Strength (% hypochlorite)	6-8
Max. Dosage at Design Flow (mg/L Cl ₂)	25
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	1,334
Type	FRP
Pumps	
Number	3
Capacity (gpm)	10.43
Type	Diaphragm
Mixers	
Number / Type	4 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC15XP / 15 hp / Water Champ

7.2.2.2 Identified Needs and Issues

The needs and issues identified for Belle Isle were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Belle Isle chemical feed system has the following issues:
 - The chemical piping is complex and congested. This is due to the available space being small for the three diaphragm-style pumps installed in a manufacturer's skid containing some potentially unnecessary pipe branches and components. Smaller footprint pumps and simplified piping could reduce complexity and congestion.
 - Chemical feed pumps are on large skids and removal of the skid would require significant pipe disassembly. A means of removing assemblies weighing more than 100 pounds is desired.

These issues are addressed in Replace Chemical Feed System (Project BLI-DIS-1) in the following bullets.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project BLI-DIS-2) in the following section.
- Complex recirculation pumps piping which makes it difficult to access pumps. This issue is addressed in Replace Chemical Recirculation System with Simplified System (Project BLI-DIS-3) below.

7.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project BLI-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities are included in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, BLI-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 7-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 was obtained from the replacement costs of the SRP.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 were estimated based on manufacturer pump rebuilds at an average cost of \$20,000 per year and GLWA onsite rebuilds at an average cost of \$12,000 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10 and routine maintenance. This frequency is based on GLWA's experience at Conner Creek.

Table 7-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 7-4. Alternative Evaluation for Replace Chemical Feed System (Project BLI-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 234,619	\$ 32,000	\$ 909,487	\$ 436,554	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2

	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Project BLI-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue included in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-Paced and TRC-Paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation for these alternatives is presented in Table 7-5. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be consistently met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 7-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project BLI-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Replace existing chemical feed control system utilizing current level of controls and	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Replace Chemical Recirculation System (Project BLI-DIS-3). The recirculation pumps' piping is unusually complex, which is readily apparent when compared to that at the Oakwood CSO facility. The area available for recirculation on the opposite side of the tanks from the feed pipes is small and the unnecessary complexity results in poor access to the pumps. The two alternatives are:

- 1) **Alternative 1: Do Nothing.** Maintain existing system.
- 2) **Alternative 2: Replace Chemical Recirculation System with Simplified System.** It is recommended that the complex recirculation pump and piping layout be replaced with a single pump per tank recirculation patterned after Oakwood (Figure 7-4).

Figure 7-4. Comparison of Complex Piping at Belle Isle (left) and Simplified Chemical Piping at Oakwood CSO Facility (right)

The alternative evaluation is presented in Table 7-6. Capital costs for each alternative are presented in Volume 6 – Appendices, Appendix C under this project title. This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than Alternative 1 based on the improved O&M provided by simplified piping. The NPV/Benefit cost for Alternative 2 is \$67,500, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the ease of O&M with this alternative, Alternative 2 – Replace Chemical Recirculation System with Simplified System, is the recommended alternative.**

Table 7-6. Alternative Evaluation for Replace Chemical Recirculation System (Project BLI-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Maintain existing system	Water Quality & Compliance	3

	<i>Disadv.:</i>	Poor access to pumps.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Chemical Recirculation System with Simplified System	Health and Safety	3	3.22	\$ 217,000	\$ -	\$ 217,000	\$ 67,461	Not Applicable
	<i>Definition:</i>	Replace existing piping with straight-forward piping.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less pipe to maintain.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.3 Odor Control

7.2.3.1 Description of Existing System

The Belle Isle odor control system is a vertical flow, single dual-bed vertical carbon adsorber. The odor control fan pulls foul air from the screenings chamber, mixing chamber, and retention basin when liquid is detected in any of these areas. Carbon is replaced through the top and side access hatches on the vessel.

The system was installed in 2007. Overall, the system is in good condition. For a detailed condition assessment of individual odor control assets, see CS-299 Condition Assessment.

This odor control system operates under air permit requirements (Permit to Install No. 333-07). The emission limit is 0.0107 pounds per hour of hydrogen sulfide. At a design air flow of 8,800 cfm, this equates to approximately 0.23 ppm concentration of hydrogen sulfide. The carbon is tested for remaining bed life on a quarterly basis as required by the permit. Carbon was replaced in February 2019, which was the first time it was replaced since it was put into service.

Per GLWA, no odor complaints have been received for at least the past 3 years.

7.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- The odor control vessel has a dome top which increases the risk of slipping during carbon replacement.
- Accessing the top bed of the media for sampling is not easily performed. Jacobs investigated this issue further for this evaluation and the findings and recommendations are presented in the following paragraphs.

Quarterly carbon samples are taken from the top bed so that the final layer of carbon media can be analyzed to test for breakthrough. The final layer of carbon media is not accessible in the bottom bed. Accessing the top bed requires two operations staff to safely hold the ladder against the cylindrical vessel while a third staff members scales the ladder and opens the top hatch to collect the sample.

During meetings with O&M staff, Jacobs suggested that the discharged air from the vessel could be sampled and analyzed for breakthrough of H₂S. Sampling of discharged air is safer and less labor intensive than carbon media sampling. However, air sampling also requires the facility to be in operation during a wet weather event. Due to the multiple other duties of O&M staff during a wet weather event, GLWA decided to continue sampling the carbon media, which can be done during dry weather periods.

As an alternative to sampling carbon through the top access hatch, carbon may be sampled from one of the six sample ports on the side of the carbon vessel. Three ports are provided for each carbon bed. Carbon should be sampled from one of the two ports shown on Figure 7-5. These ports are located near the discharge end of each carbon bed. The lower port may be sampled from ground level. A grain thief is necessary to obtain a sample from the ports. A grain thief (see Figure 7-5, <https://www.globalgilson.com/sampling-probes>) is a device used for obtaining a grain sample from a silo and can be constructed from PVC or purchased from agricultural supply stores and other online sources. Carbon analysis is a common service provided by most activated carbon suppliers or can also be performed by many analytical laboratories.

Figure 7-5. Carbon Sample Ports (left) and Grain Thief (right)

7.2.3.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative

Access to Odor Control Vessel (Project BLI-OC-1). Staff indicated that the recent carbon replacement at the facility required constructing scaffolding to safely access the top of the carbon vessel for replacing the top carbon bed. The vessel has a dome top increasing the risk of slipping.

Jacobs evaluated two alternatives that would make accessing the top of the carbon vessel safer for both sampling and carbon replacement and compared it to the current approach. Alternatives include:

- 1) **Alternative 1: Erect scaffolding for Carbon Replacement.** The O&M staff currently erects a scaffolding when replacing the carbon. The carbon needs to be replaced about every 10 years.
- 2) **Alternative 2: Ladder and Railing System.** Figure 7-6. shows a ladder and railing alternative. A contractor would field install fiberglass clips and receptacles to the existing fiberglass tank to secure the ladder and railing. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps. The figure does not show a 6-in. toe rail, which is recommended, that should be installed at the bottom of the railing to help prevent a person's foot from slipping off the domed top along with tools and equipment.

Figure 7-6. Example of Ladder and Railing (figure is not Belle Isle's odor control system)

- 3) **Alternative 3 - Ladder, Platform and Railing System:** Figure 7-7 shows an example of a ladder, platform, and railing on a horizontal tank. The platform provides a more stable working surface than the domed top. The option is a safer option because the platform provides a flat surface on which to stand. A contractor would field install fiberglass clips and receptacles to the existing fiberglass tank to secure the ladder, platform, and railing. Installation of the platform and rail option is more expensive than the railing only option (Option 1) as a crane is necessary to remove the metal roof and lower the platform from above. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.

Figure 7-7. Example of Ladder, Platform and Railing (figure is not Belle Isle's odor control system)

The alternative evaluation for these alternatives is presented in Table 7-7. The sources of costs used in this evaluation are listed below:

- The O&M cost for Alternative 1 is based on \$15,000 for erecting scaffolding. Because the carbon is replaced once every 10 years, the annual O&M cost is assumed to be \$1,500.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Ladder and Railing System has a Total Benefit score 1.0 higher than Alternative 1 – Erecting Scaffolding due to the improved safety and the ease of O&M. Alternative 2 also has the lowest NPV/Benefit cost. **As such, Alternative 2 – Ladder and Railing System, is the recommended alternative.**

Table 7-7. Alternative Evaluation for Access to Odor Control Vessel (Project BLI-OC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Erect Scaffolding for Carbon Replacement	Health and Safety	2	2.50	\$ -	\$ 1,500	\$ 31,634	\$ 12,654	
	<i>Definition:</i>	Continue to use scaffolding when replacing carbon.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Must be set up every time carbon is replaced.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Ladder and Railing System	Health and Safety	4	3.50	\$ 41,000	\$ -	\$ 41,000	\$ 11,714	Best Value Alternative
	<i>Definition:</i>	Provide a ladder on side of vessel and railing around top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Ladder provides improved access and railing provides safety during carbon change-out.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Surface of dome is still sloped and not as safe as a flat surface.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Ladder, Platform, and Railing System	Health and Safety	5	4.00	\$ 162,000	\$ -	\$ 162,000	\$ 40,500	
	<i>Definition:</i>	Provide a ladder on side of vessel and a platform and railing system on top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Platform provides more stable working surface of top of vessel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

7.2.4 Flushing and Dewatering

7.2.4.1 Description of Existing System

Dewatering System: After a wet weather event that fills the basin, the basin, screen channel, and mixing channels are dewatered by gravity back to the Belle Isle Pump Station, and subsequently pumped to the DRI and then to the WRRF.

Flushing System: Each basin contains a single flushing gate. After the basin is dewatered, the water in the flushing reservoirs (or NPW, if necessary) is used to flush the solids from the floor of the basins. The flushed solids flow by gravity to the Belle Isle Pump Station.

Table 7-8 provides an overview of the existing flushing and dewatering system at Belle Isle CSO facility.

Table 7-8. Overview of Existing Flushing and Dewatering System at Belle Isle CSO Facility

Parameter	Value
Total Basin Volume (MG)	0.3
Headworks and Basin Dewatering and Flushing System	- Each basin has one flushing gate - Flushed solids are routed by gravity to Belle Isle Pump Station

7.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids can accumulate in the corners of the mixing channels
- Local control of the valves in the two basin dewatering valve vaults requires confined space entry into the vaults. This issue is addressed in the I&C section (Section 7.2.7).

7.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing System in Mixing Channel (Project BLI-FD-1). Review of the 3-D scanning results for CS-299 showed that there was a build-up of solids in the corners of the mixing channels. A means to spray these locations is needed. There are two alternatives for addressing the solids buildup in the corners of the mixing channels. These alternatives include:

- Alternative 1: Do Nothing/ Manual Flushing Build-Up Solids.** Allow solids to build-up and manually flush once every 3 months. One of the disadvantages of this alternative is that the solids in the mixing channels that are not removed after draining the basin may affect subsequent disinfection.
- Alternative 2: Flushing System in Mixing Channel.** The recommended improvement includes mounting a 4-in. HDPE header along the perimeter of the mixing channel approximately 3 ft above adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B, for figures (Figure BLI-FD-1-ALT-2) showing conceptual layouts. The HDPE header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 0.75-in.-diameter) that create a water jet. The proposed hole spacing along the header is 18 to 24 in. A total flow rate of 250 gpm is required to adequately remove settled materials from the concrete shelf above the dry weather flow channel and

maintain adequate volume and velocity to carry materials into the dry weather flow channel following a CSO event.

Onsite NPW will be required. The final designer should confirm that the pressure in the existing water line is adequate (15 to 20 psi at the drilled hole) to meet the flushing requirements. The intent will be to use existing water pressure and not a booster pump. The 4-in. HDPE header should be connected to the interior NPW system piping. Following a wet-weather event, a motor operated solenoid/gate/ball control valve will be opened to charge the flushing header. The control strategy assumes that solenoid is activated for a set duration (minimum of 15 minutes) after the level sensors in the mixing channel record a water level rise above elevation 95.0 ft and subsequent water level drop.

A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying.

During initial operation, onsite staff should visually inspect the mixing channel area to confirm settled materials have been adequately removed and then adjust the control system timer to increase/decrease the flushing duration as needed until the system has been optimized. Provisions to flush the header pipe could be provided by adding another automatically operated valve at the terminal end of the header to open at the start of the flush event and flush any accumulated debris from the pipe. Integration with the facility's SCADA and LC) system is required to achieve this functionality. New electrical connections to the new control valve are also required (110 V).

The alternative evaluation for these alternatives is presented in Table 7-9. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M cost for Alternative 1 assumes two personnel for 4 hours each day for manually flushing the mixing channels every 3 months.
- The O&M cost for water usage is assumed to be the same for the two alternatives, and therefore, not included in the O&M costs.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 1 – Do Nothing/ Manual Flushing Build-Up Solids, has the lowest NPV/Benefit cost and is considered the Best Value Alternative. **As such, Alternative 1 – Do Nothing/ Manual Flushing Build-Up Solids is the recommended alternative.**

Table 7-9. Alternative Evaluation for Flushing System in Mixing Channel (Project BLI-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Manual Flushing Solids Build-Up	Health and Safety	2	2.22	\$ -	\$ 3,200	\$ 67,487	\$ 30,445	Best Value Alternative
	<i>Definition:</i>	Allow solids to build-up and manually flush.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Solids in the mixing channels that are not removed after draining the basin may affect subsequent event water quality.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing System in Mixing Channel	Health and Safety	4	3.50	\$ 151,000	\$ -	\$ 151,000	\$ 43,143	
	<i>Definition:</i>	Install a spray flushing system in each mixing channel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Solids are removed from the mixing channel after every storm.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased assets to maintain.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.5 HVAC

7.2.5.1 Description of Existing System

The Belle Isle facility consists of a headworks, chemical room, odor control room, electrical room, mechanical room, control room, sample room, and restrooms. The facility also includes an adjoining retention basin. Table 7-10 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, sanitary system, electric water heater, electric water cooler and emergency shower/eye washes. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 7.2.10.

Table 7-10. Major HVAC Equipment at Belle Isle CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	WEF-2 and 3	Wall Exhaust Fans	3,350 cfm
	MAU-1	Make-up Air Unit	6,700 cfm
Basin	REF-1 and 2	2 × Roof Exhaust Fans	6,500 cfm
Chemical Room	WSF-1	Wall Supply Fan	1,600 cfm
	IEF-1	Inline Exhaust Fan	1,600 cfm
	EUH-1 and 2	Electric Unit Heater	2,450 cfm 25 kW
Electrical Room	IEF-2	Exhaust Fan	1,000 cfm
	IEF-3	Exhaust Fan	3,700 cfm
	EUH-5	Electric Unit Heater	580 cfm 5 kW
	EUH-6	Electric Unit Heater	5 kW

Notes:

kW = kilowatt(s)

Table 7-11 provides a summary of the basis of design performance criteria for HVAC systems at Belle Isle and Table 7-12 provides the outdoor Basis of Design conditions.

Table 7-11. Belle Isle Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Headworks Area	Class I, Div 2, Group D (Per As-Built Drawings)	60	N/A	12 ACH (Occupied)
Mechanical Room, Electrical Room	Unclassified	60	104	1 ACH (Mechanical Room) 1 ACH (Electrical Room)
Odor Control Area	Class I, Div 2, Group D (Per Basis of Design)	72	75	6 ACH (Occupied) 2 ACH (Unoccupied)

Winter (Dry Bulb F)	Summer (Dry Bulb °F)	Summer (Wet Bulb °F)
3	91	73

7.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- MAU-1 provides inadequate heat for Headworks Area: It was noted by O&M staff that this unit does not provide enough heat in the winter. However, no frozen pipe issues were noted in this area.
- Corrosion of Unit Heaters (UH-1 to UH-6). It was noted that half of Trane UHXA unit heaters at the facility have been recently replaced by GLWA's HVAC contractor due to corroding of copper soldering in the unit.
- Frequent failures of DX cooling coil in AHU-1. It was reported in the meetings that the Trane AC unit fails every year.
- Chemical room unit heater and exhaust fan are difficult to access due to the tight conditions in the room and the poor accessibility.
- The backflow preventer occasionally sprays water in the sample room.
- Occasional low water pressure at the facility: See Site Section 7.2.8.2 for discussion of this issue.
- Difficulty accessing chemical room HVAC equipment for maintenance: GLWA's HVAC contractor confirmed that accessing exhaust fan and unit heater in the chemical room for maintenance is very difficult. Routine maintenance has required the erection of scaffolding.

During site investigations (June 2020) the following observations were noted:

- Both Trane UHXA unit heaters in the chemical room had been replaced by Indeeco Ultra-Safe EXP unit heaters.
- The door between the electrical room and the adjacent Corridor was held open with a rope.
- Explosion proof unit heaters were provided throughout the facility including in spaces without explosion proof electrical equipment and lighting fixtures such as the electrical room and chemical room.
- The Trane UHXA unit heater in the electrical room had been replaced with an Indeeco Ultra-Safe EXP unit heater.

- The supply and exhaust fans in the odor control area were observed to be not running.
- The supply and exhaust fans in the chemical room are very difficult to access for maintenance due to their locations. See Figure 7-8. below.

Figure 7-8. Chemical Room Supply and Exhaust Fans Located in Inaccessible Area

- The exhaust fans were observed to not be running in the Headworks Area.
- Opening the Basin access hatches did not start either of the Basin exhaust fans. The fans should start when the hatch is opened.

7.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project BLI-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) Alternative 1: Do Nothing/ Replace In-Kind.

- Replace MAU-1 in kind.

2) Alternative 2: HVAC Improvements including,

- Odor Control Area ventilation improvements
- Odor Control Area fan maintenance access
- Headworks ventilation

- Unit heater replacement
- Improved cooling for control room and sample room
- Improved access for chemical room HVAC equipment
- Water spray from backflow preventer

Each of the HVAC related improvements listed above are described further below:

Odor Control Area Ventilation Improvements. The 2003 Basis of Design report indicates that both the Chemical Room and the Odor Control Room were classified as Class I, Division 2 per NFPA 820; however, all other spaces aside from the Headworks Area and Basin were indicated as unclassified. Jacobs notes that chemical rooms are not Class I, Division 2 spaces. Rather, they are unclassified spaces, provided they are physically separated from classified spaces. The Chemical Room therefore does not require explosion-proof equipment such as the explosion-proof unit heaters currently installed in this space.

Per NFPA 820-2003, which was in effect when the facility was designed, the Odor Control Room is considered a Class I, Division 2 space if it is not continuously ventilated at 6 air changes per hour (ACH). However, the exhaust and supply fans in the odor control area were sized based on 6 ACH, which would make the area unclassified. Jacobs notes that the fans must run continuously and ventilation monitoring on both the supply and exhaust fan is required to detect no airflow. Ventilation failure and combustible gas in excess of 10 percent of the Lower Explosive Limit needs to be alarmed with visual and audible alarms at the entrance to the odor control area as well as inside the space.

It is recommended that the Odor Control Room be made unclassified by meeting the requirements noted above. Continuous ventilation of the odor control area and providing slight negative pressurization with respect to the atmosphere should have the added benefit of reducing H₂S levels in the electrical room, which was likely the cause of the need to replace the Trane UHXA unit heaters.

It should be noted that although it is not a code requirement, current best practice is to physically separate electrical rooms from spaces with corrosive conditions (e.g., the Odor Control Room) and to positively pressurize the space with respect to these areas. If the Odor Control Room is provided with negative pressurization with respect to adjacent spaces this most likely will not be necessary but if corrosion of the equipment in the electrical room becomes an issue it should be considered.

Odor Control Area Fan Maintenance Access. It is difficult to access WSF-2 and WEF-1 for maintenance purposes due to their locations high in the space and the proximity of conduit and piping restricting ladder access from below (Figure 7-9).

Figure 7-9. Odor Control Room Exhaust (left) and Supply (right) Fan Poorly Accessible

Access to WEF-1 could be provided by installing a platform which would be accessed from the landing outside of mechanical room on the second floor. This would effectively be an extension of the existing landing. WSF-1 could be provided with a platform with ladder access. This project should be coordinated with the Improved Access to Odor Control Vessel (Project BLI-OC-1) project.

Headworks Ventilation. Per the electrical record drawings, the Headworks area is electrically a Class I, Division 2 space which requires ventilation at a continuous rate of 12 ACH. Neither the odor control unit (which exhausts air from the Basin and Headworks Area), nor the Headworks Area exhaust fans were observed to be running during the site visit. This means the space is effectively a Class I, Division 1 environment containing equipment only rated for a Class I, Division 2 environment. It was also noted that Headworks Area exhaust fan WEF-3 is located only approximately 3 ft from odor control area supply fan WSF-2 (see excerpt from HVAC drawings below). When both fans are running, air being exhausted from the Headworks Area will be introduced into the odor control area by WSF-2 (Figure 7-10). This could have contributed to the corrosion which lead to the need to replace the Trane UHXA unit heaters.

Figure 7-10. Short-Circuiting of Airstreams Between WEF-3 and WSF-2

In addition to issues with short-circuiting of the air streams between WEF-3 and WSF-2, MAU-1 has a duct which runs from the mechanical room through the odor control area to the headworks area (Figure 7-11). The ductwork between the classified Headworks Area and the unclassified mechanical room is a breach in physical separation as defined by NFPA 820 and effectively classifies the entire building with the same classification as the Headworks Area.

Figure 7-11. Ductwork Passing Between Classified and Unclassified Areas

It is recommended that MAU-1 be removed and replaced by either a MAU located at the ground level near the Headworks Area or a supply fan with the same capacity as MAU-1 and explosion proof unit heaters. For cost estimating purposes, a new supply fan and unit heaters are assumed. Locating the supply fans or MAU on the North side of the Headworks Area and relocating WEF-3 to the South side would have the benefit of eliminating the short-circuiting currently occurring between WEF-3 in the Headworks Area and WEF-2 in the odor control area.

Increased MAU-1 Heating Capacity (if necessary). MAU-1 serves the Headworks. It was noted by O&M staff that this unit does not provide enough heat in the winter. The basis of design dry bulb temperature for the Headworks area is 60°F, so it is possible that this area could be perceived as being cold in the winter. No pipes have frozen in the past in this area. If additional heating is desired in this space, a unit with increased heating capacity should be provided with the new MAU described in the project above.

Unit Heater Replacement. The Trane UHXA unit heaters at the facility have an aluminum-finned tubular steel heat exchanger which is directly exposed to the air stream when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail, they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating that has passed the ASTM International Method B117 salt-spray test. The Indeeco units are a good selection for the electrical room and odor control area. If the odor control area is unclassified, they are not required to be explosion-proof. Based on the recommendation to replace the units when they fail, their cost is not included in the capital cost estimate, rather, they are in the SRP.

The Indeeco units currently installed in the chemical room should last longer than the Trane UHXA units which they replaced; however, even 316 stainless steel is also susceptible to corrosion by sodium hypochlorite.

Improved Cooling for Control Room and Sample Room. GLWA's HVAC contractor noted that while there have been mechanical failures in AHU-1 in the past, the failures were not out of the ordinary in terms of frequency or severity and have been reportedly rectified.

It is likely that AHU-1 could appear to be under-performing in terms of cooling due to the fact that when the space is unoccupied, the setpoint is controlled to increase to 85°F. Operators visit the facility infrequently and in the short amount of time they are at the facility the temperature in the spaces served by AHU-1 (i.e., the sample room, control room, men's and women's restrooms, and corridor) may not reach the Basis of Design temperature of 72°F.

In order to improve operator comfort when the facility is occupied it is recommended that split direct expansion (DX) units be installed in the sample room and control room. The evaporator units in the split DX systems could be configured to discharge in locations where operators are likely to be located and would provide a faster response to occupancy than the current system configuration. The proposed split DX units would be provided in addition to the existing AHU-1 cooling coil and would be provided with their own thermostat.

Improved Access for Chemical Room HVAC Equipment. GLWA's HVAC contractor noted the need to erect scaffolding to perform maintenance on the unit heater and exhaust fan in the chemical room. Jacobs recommends either (1) installing a platform with ladder to allow for maintenance on the exhaust fan and relocating the unit heater to an area where ladder access is possible, or (2) evaluating and possibly repositioning the supply and exhaust fans closer to the floor when the chemical feed system is re-designed in the future (as described in the CS-299 Disinfection technical memorandum).

Water spray from backflow preventer. During the site visit water was noted on the floor near the backflow preventer with no drain near the unit (Figure 7-12). Jacobs recommends the installation of

an airgap fitting with hose attachment and running the hose to the nearest drain. This should address the water spray.

Figure 7-12. Water Spray Near Backflow Preventer

The alternative evaluation is presented in Table 7-13. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for MAU-1 in Alternative 1 was obtained from the SRP. It should be noted, however, that replacement of the MAU in its current location would likely not be code compliant.
- The O&M costs for Alternative 1 include scaffolding costs (to perform maintenance on the unit heater and exhaust fan in the chemical room).
- The capital costs for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 1 is the Best Value Alternative. However, replacement of the MAU in its current location would likely not be code compliant. In addition, Alternative 2 has a total benefit score about 1.0 higher than the Alternative 1 based on the improved health and safety and improved O&M. **As such, Alternative 2 - HVAC Improvements is the recommended alternative.**

Table 7-13. Alternative Evaluation for HVAC Improvements (Project BLI-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	2	2.50	\$ 63,500	\$ 2,000	\$ 99,591	\$ 39,836	Best Value Alternative
	<i>Definition:</i>	No improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lack of code compliance, difficult, less safe, and more costly maintenance, corrosive gases entering building, and control room discomfort.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	4	3.50	\$ 293,000	\$ -	\$ 293,000	\$ 83,714	
	<i>Definition:</i>	Addition of Odor Control area ventilation monitoring to meet code requirements, replacement of MAU-1 with new system, improved fan access for maintenance, and supplemental air conditioning.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, easier and safer maintenance, more comfortable control room conditions.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.6 Electrical

7.2.6.1 Description of Existing System

The Belle Isle electrical system consists of one DTE utility feed from a 1,000 kVA, 480 V, 3-phase outdoor transformer (primary metering) and one diesel generator feed from a 750 kilowatts (kW), 480 V, 3-phase stationary generator. The feeds are connected to a 1,200 A switchboard with electrically operated breakers and automatic source transfer controls. The switchboard then feeds a 1,200 A motor control center (MCC). The MCC then feeds the various pumps, valves, motors, transformers, panels, etc. at the facility. The Belle Isle Pump Station is fed from the CSO facility MCC; however, it is not included in this facility assessment, per the CS-299 Scope of Work. Table 7-14 provides a summary of the major electrical equipment for this facility.

Table 7-14. Major Electrical Equipment at Belle Isle

Location	Major Electrical Equipment	Description
Electrical Room	Main Switchboard/ATS	1,200 A, 480/277 V, 3-Phase
Outdoors	Generator (Diesel)	750 kW, 480 V, 3-Phase
Electrical Room	MCC	1,200 A, 480/277 V, 3-Phase

7.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

7.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project BLI-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting, however it will be less safe when operating at night and when accessing area downstream of screens.
- 2) **Alternative 2: Electrical Improvements.** Add lighting at the following location (and shown on the electrical drawings - Figure BLI-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin – Add additional external lighting on top and the riverside of the basin. Lighting foot-candles will meet the requirements of the local outdoor lighting ordinances.

The alternative evaluation is presented in Table 7-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting. The NPV/Benefit cost for Alternative 2 is \$16,500, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 7-15. Alternative Evaluation for Electrical Improvements (Project BLI-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 58,000	\$ -	\$ 58,000	\$ 16,571	Not Applicable
	<i>Definition:</i>	Add additional external lighting on top and the riverside of the basin.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.7 I&C

7.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2007 under PC-753. This project upgraded the existing Belle Isle Pump Station facility to include the new CSO basin facility. In 2014 under PC-773D, the Ovation system controllers and software were upgraded to version O.V.3.5.0.

The facility's Ovation network currently has only one primary network switch. The switch is connected to the GLWA AT&T wide area network via the system's router. The system has one database server and one operator workstation located in the control room. The system has a pair of Ovation controllers that provide the facility with redundant local controls and I/O capabilities. All network connections in the Belle Isle facility are via copper Ethernet cables. The controllers are connected to the network via a single-homed connection, which means each controller has only one connection to the network switch. Since there is only one network switch, the primary switch is a single point of failure for the overall system. The current system is equipped with a back-up radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 7-16 summarizes the level sensors and flow meters at the Belle Isle CSO Facility used to monitor flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 7-16. Summary of Flow Meters and Level Sensors at Belle Isle CSO Facility

Area	Quantity	Instrument Type
CSO Level Sensors		
Screening Chambers	2	Ultrasonic
	2	Radar (Back-up)
Mixing Chambers	2	Ultrasonic
	2	Radar (Back-up)
Basin 1 and 2	2	Ultrasonic
	2	Radar (Back-up)
Flush Water Storage	2	Ultrasonic
	2	Radar (Back-up)
Chemical System Flow Meters		
Chemical Feed		
To upper mixers	2	Magnetic
To lower mixers	2	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic

7.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets:

- GLWA requested to have the ability to control the Belle Isle CSO Facility from Conner Creek to improve operational efficiency during CSO events.
- GLWA requested that Jacobs investigate the potential removal of gas monitors in the basins for Belle Isle to reduce instrumentation maintenance requirements.
- GLWA requested process cameras at select locations to improve monitoring of the facility during wet weather operation.
- Local control of the valves in the two basin dewatering valve vaults requires confined space entry into the vaults.
- Generator and ATS controls do not adequately report alarm signals into Ovation and are becoming less reliable. This issue is being addressed in an on-going project and is therefore not included in the capital improvement projects for CS-299.
- Update Ovation control system to the latest version and increased monitoring capabilities.
- Control system network lacks redundancy.

7.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project BLI-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, all of the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into multiple delivery projects, if needed. There are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements including,**

- Provide remote operation of Belle Isle CSO Facility from Conner Creek CSO Facility
- Investigate need for gas monitoring in CSO basins
- Provide process cameras at select locations
- Provide local control capabilities of actuators in valve vaults

Each of the I&C related improvements listed above is described further below:

Provide remote operation of Belle Isle CSO Facility from Conner Creek CSO Facility. GLWA requested to have the ability to control the Belle Isle CSO Facility from Conner Creek to improve operational efficiency during CSO events. The physical infrastructure is in place to allow this to happen. It is recommended that GLWA investigate the programming through SCADA to determine if the code has already been written and activate if that is the case. If the existing programming in SCADA does not contain code for remote control of Belle Isle from Conner Creek, provide additional programming for this functionality.

Investigate need for gas monitoring in CSO basins. Eliminate gas monitoring equipment in accordance with Section 5.4.7.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Provide local control for valves in valve vaults above ground (outside of vault). Local control of the valves requires confined space entry. Providing controls above ground, outside of the valve vault would improve safety, when local control of the valves may be needed.

The alternative evaluation is presented in Table 7-17. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M costs for Alternative 1 assume that the lack of remote control of the Belle Isle facility requires additional operator time every wet weather event.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- O&M costs for Alternative 2 include an estimated annual cost for maintenance of the proposed cameras.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative because the NPV/Benefit cost of Alternative 1 is about \$7,000 lower than that of Alternative 2. The total benefit score for Alternative 2 is 1.3 higher than Alternative 1, due to improved health and safety, and ease of O&M. Based on the higher total benefit score and the small difference in NPV/Benefit cost, **Alternative 2 - I&C Improvements is the recommended alternative.**

Control System Upgrade (Project BLI-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2. As part of this project, it is recommended to increase network switch redundancy. Adding a back-up network switch within the system will eliminate the single point of failure of the primary network switch. Once the back-up network switch is added, the connections to the network equipment and Ovation controllers will need to be converted to a dual-home configuration instead of single-home connections. This will provide full redundancy and should one of the networks fail, the second network will remain available for monitoring and control.

Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 7-18 provides the summary of the **Control System Upgrade, which is the recommended alternative.**

Table 7-17. Alternative Evaluation for I&C Improvements (Project BLI-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ 4,000	\$ 84,359	\$ 33,743	Best Value Alternative
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Unexpected conditions may occur in the Headworks	Component Performance	3						
	<i>Comments:</i>	Annual O&M without remote control of basin: 10 events; 4 hrs per event; \$100/hr	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	5	3.78	\$ 112,000	\$ 2,000	\$ 154,179	\$ 40,752	
	<i>Definition:</i>	Provide local control of valves without entering valve vault, install cameras for monitoring of process areas, and eliminate gas monitoring in CSO basins.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance (with reduction of gas monitoring), and more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance (with addition of cameras)	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Table 7-18. Alternative Evaluation for Control System Upgrade (Project BLI-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 922,000	\$ -	\$ 922,000	\$ 307,333	Best Value Alternative
	<i>Definition:</i>	Upgrade control system to latest version of Ovation.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Allows for use of high performance graphics and provides other benefits.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

7.2.8 Site

7.2.8.1 Description of Existing Site

The Belle Isle CSO Facility was constructed in 2009. The site includes the CSO facility and a sanitary pump station used to pump sanitary and retained storm flows from Belle Isle to the DRI on the west side of the Detroit River. The total area of the site is approximately 0.85 acres and includes an access road, parking area and fencing. The security fencing is 6-ft tall. There is a 24-ft wide sliding gate at the southern corner of the fenced-in area, as well as multiple smaller swing gates in other parts of the fence.

Site access/egress is by access road off of Sunset Drive. A parking area is located along the west side of the site to accommodate parking for O&M personnel and visitors. The access road and parking area consist of concrete pavement. The reinforced concrete sidewalk is 5 in. thick with 2 in. of aggregate base course. The rest of the reinforced concrete pavement on site is 10 in. thick with 9 in. of aggregate base course.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

7.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Inadequate space or turning radius inside the site for the sodium hypochlorite tanker trucks to maneuver through the site.
- Water ponding near the entrance gates.
- GLWA Operations has experienced issues at the basin roof drain scupper outlets as they get plugged by leaves and debris resulting in ponding on the basin surface.
- Investigate occasional low water pressure. GLWA has experienced low pressure in the incoming potable water line to the Belle Isle CSO facility in the past. The watermain servicing the facility is 6-in.-diameter. Based on discussions with GLWA after the Needs Assessment meeting, GLWA staff believes the pressure issues may have been related to Detroit Water and Sewerage Department closing valves and changing flow paths during their operation of the system (now done by the State of Michigan). This may have resolved the issue. Pressure monitoring of the water pressure at the fire hydrant outside the facility could be performed over an extended period of time (i.e., a few months) to better determine the timing and magnitude of the issue, if this is still an issue in the future.
- Seal concrete pavement joints of service drive and parking area to ensure serviceability. This could be considered a preventative maintenance item; however, for this evaluation, costs have been included in the Site capital improvements to address any concrete pavement joints or other repairs.

7.2.8.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project BLI-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Tanker Truck Access
 - Address Ponding Near Service Drive Entrance
 - Improve Basin Surface Drainage

Each of the site related improvements listed above are described further below:

Tanker Truck Access: The sodium hypochlorite fill station is located on the south side of the facility. Tanker trucks must access this location several times a year for hypochlorite delivery. Currently, the trucks pull up on a temporary unpaved access drive next to the City's barricade storage yard outside of the fence line, and then run a hose through a manway gate to the fill station to offload the hypochlorite. There is not adequate space or road turning radius inside the site for the tanker trucks to maneuver through the site. Trucks accessing the truck fill station outside the fence is not ideal as trucks could get stuck in the soft grade while pulling up and turning on the site.

It is recommended that the concrete pavement be extended parallel to the existing drive from the entrance service drive to the truck fill location, and then extended southward with adequate paved area to provide adequate turning radii for the tanker truck to turn to the south and back up to the manway gate at the point of the truck fill (see Figure BLI-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B).

Address Ponding Near Service Drive Entrance: A low point in the existing site grading exists on the north side of the service drive near the entrance gate to the facility. This is an area where water encroaches on the service drive frequently and can be a nuisance, particularly in winter months when icing on the service drive is a concern. It is recommended that a catch basin be installed at this location and connected to the existing storm sewer near this low point.

Improve Basin Surface Drainage: The basin roof is sloped from south to north with drain scuppers located through a parapet wall that allow drainage through the wall to downspouts. GLWA Operations has experienced issues at the scupper outlets as they get plugged by leaves and debris resulting in ponding on the basin surface.

One alternative could be to remove the trees near the basin and replace them with a lower growing tree or shrub. Another alternative could be that the sizes and number of scuppers be evaluated, and appropriate modification be made to the scuppers to prevent leaves and debris from blocking the scupper outlets. Coring holes directly into the basin roof to provide additional drainage relief may also be considered as an alternative to work along with the existing scupper system.

The alternative evaluation is presented in Table 7-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than Alternative 1 based on the improved health and safety and improved O&M provided by the various site improvements. The NPV/Benefit cost for Alternative 2 is \$63,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 7-19. Alternative Evaluation for Site Improvements (Project BLI-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Maintain current operation for hypo deliveries and do not address ponding.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Trucks could get stuck in the soft grade while accessing the site & safety issue with ponding water.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 220,000	\$ -	\$ 220,000	\$ 62,857	Not Applicable
	<i>Definition:</i>	Improved tanker truck access, address ponding near service drive entrance, and improve basin surface drainage.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved maneuverability and safety during hypo deliveries & improved safety for accessing facility.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.9 Architectural

7.2.9.1 Description of Existing Facilities

The Belle Isle CSO Facility includes the CSO facility and a sanitary pump station used to pump Belle Isle sanitary flows to DRI on the west side of the river. The treatment facility consists of a chemical room, odor control room, utility support (electrical and mechanical), control room, sampler room, screen room and other miscellaneous rooms. The facility also includes an adjoining retention basin.

7.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 7-20. As such, the roof should be replaced in-kind and the costs and schedule for roof replacement will come from the SRP.

Table 7-20. 60-Year Life Cycle Cost Evaluation of Shingled vs. Metal Roof for Belle Isle Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$70,000	\$233,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life Cycle Cost (NPV) Discounted at 2.4%	\$190,000	\$233,000

^a Based on 4,650 ft² roof area; \$15 ft² for shingle roof and \$50/ft² for metal roof.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because the items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

7.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (BLI-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control /expansion wall joints
 - Remove and replace isolation /cove joint sealant and around building perimeter
 - Clean concrete bollards, patch, prepare surface and coat
 - Repoint mortar joints
 - Remove damaged coating, prepare surface, patch and apply coating to coping.

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure BLI-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (BLI-DIS-1).

The alternative evaluation is presented in Table 7-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 7-21. Alternative Evaluation for Architectural Rehabilitation (Project BLI-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 243,000	\$ -	\$ 243,000	\$ 78,387	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

7.2.10 Safety

7.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

7.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 7-22. The capital improvement project to address these issues is included in the table.

Table 7-22. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Chemical Room	Top and mid-rail fall protection needed at ladder access at top of tanks	Add swing gate (original recommendation was to add chain; however, this is no longer current GLWA practice)	Safety Improvements (Project BLI-SAFE-1)
Chemical Room	Emergency eyewash/shower is at different level from tank and pumps and it is partially obstructed by door	Relocate eyewash/shower	Safety Improvements (Project BLI-SAFE-1)
Odor Control Room	No illuminated exit signs	Add or replace exit signs	Exit Sign Improvements ^a
Odor Control Room	Concrete pad creates uneven exit access to exterior door	Remove section of concrete pad	Safety Improvements (Project BLI-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project BLI-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

7.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section.

Safety Improvements (Project BLI-SAFE-1). This project should address the safety issues identified above. These issues include:

- Add swing gate to access top of tanks in the chemical room
- Replace eyewash/shower in the chemical room
- Remove section of concrete pad in the odor control room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 7-23 shows the one alternative.

Table 7-23. Alternative Evaluation for Safety Improvements (Project BLI-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 82,000	\$ -	\$ 82,000	\$ 21,674	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, eye wash and exit signage.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

7.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at the Belle Isle CSO Facility.

7.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Belle Isle CSO facility, Table 7-24 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 7-24, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 7-24. Listing of Asset Condition Assessments for Belle Isle Facility

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable gas detector and was not assessed.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Belle Isle Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

7.3 Capital Planning for Belle Isle CSO Facility

7.3.1 Summary of Capital Improvement Plan Projects

Table 7-25 provides a summary of the recommended CIP projects and associated capital costs for the Belle Isle CSO facility based on the alternative evaluations conducted for this facility.

Table 7-25. Summary of Recommended Projects at Belle Isle CSO Facility

Project No.	Alternative	Description	Total Project Cost
BLI-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 274,000
BLI-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
BLI-DIS-3	2	Replace Chemical Recirculation System with Simplified System	\$ 217,000
BLI-OC-1	2	Ladder and Railing System	\$ 41,000
BLI-HVAC-1	2	HVAC Improvements	\$ 293,000
BLI-ELEC-1	2	Electrical Improvements	\$ 58,000
BLI-I&C-1	2	I&C Improvements	\$ 112,000
BLI-I&C-2	1	Control System Upgrade	\$ 922,000
BLI-SITE-1	2	Site Improvements	\$ 220,000
BLI-ARCH-1	2	Architectural Rehabilitation	\$ 243,000
BLI-SAFE-1	1	Safety Improvements	\$ 82,000

7.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 7-26. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 7-26. Capital Improvement Plan Projects for Belle Isle CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
BLI-1 Disinfection System Improvements	\$752,000	2028 <i>Timing based on asset condition</i>	BLI-DIS-1	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	\$ 274,000
			BLI-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
			BLI-DIS-3	Replace Chemical Recirculation System with Simplified System	\$ 217,000
			BLI-OC-1	Ladder and Railing System	\$ 41,000
BLI-2 HVAC Improvements	\$ 293,000	2033 <i>Timing based on asset condition</i>	BLI-HVAC-1	HVAC Improvements	\$ 293,000
BLI-3 Facility-Wide Electrical and I&C Improvements	\$ 1,092,000	2025 <i>Timing based on asset condition</i>	BLI-ELEC-1	Electrical Improvements	\$ 58,000
			BLI-I&C-1	I&C Improvements	\$ 112,000
			BLI-I&C-2	Control System Upgrade	\$ 922,000
BLI-4 Site Improvements	\$ 220,000	2030 <i>Timing based on best judgement</i>	BLI-SITE-1	Site Improvements	\$ 220,000
BLI-5 Facility-Wide Safety and Architectural Improvements	\$ 325,000	2023 <i>Project should be initiated as soon as possible</i>	BLI-ARCH-1	Architectural Rehabilitation	\$ 243,000
			BLI-SAFE-1	Safety Improvements	\$ 82,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 7-27 and Table 7-28 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 7-27 indicates that BLI-DIS-1 project has 13 assets that has an average condition score of 1.54 and an average replacement date of 2029. This information was used to propose a scheduled construction completion date of 2028.

Table 7-27. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BLI-DIS-1	13	1.52	1.54	2.79	12	2029	\$ 234,619
BLI-HVAC-1	1	1.29	1.50	2.25	20	2034	\$ 63,500
BLI-SCR-1	1	2.00	1.70	3.70	30	2041	\$ 489,400

Table 7-28. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
BLI-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
BLI-HVAC-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
BLI-SCR-1	1	2.00	5.00	7.00	30	N/A	\$ 489,400

7.3.3 20-Year Capital Outlay Plan

Table 7-29 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 7-29. 20-Year Capital Outlay Plan for Belle Isle CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 44,000	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 19,500	\$ -	\$ -	\$ 14,500	\$ 10,000	\$ -
2022	\$ 504,082	\$ -	\$ 504,082	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2023	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2024	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2025	\$ 8,555	\$ -	\$ -	\$ -	\$ 8,555	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2026	\$ 57,413	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 21,012	\$ -	\$ 36,401	\$ -	\$ -
2027	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2028	\$ 354,204	\$ -	\$ -	\$ -	\$ 354,204	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2029	\$ 146,878	\$ -	\$ 61,713	\$ 61,713	\$ 23,452	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2030	\$ 171,867	\$ 37,838	\$ -	\$ -	\$ 83,138	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 50,890	\$ -	\$ -
2031	\$ 183,478	\$ -	\$ -	\$ -	\$ 159,120	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ 24,358
2032	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -

2039	\$ 639,908	\$ 88,180	\$ -	\$ 291,140	\$ -	\$ 21,566	\$ 18,046	\$ 144,707	\$ -	\$ -	\$ -	\$ 76,269	\$ -
2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 3,316,439	\$ 275,614	\$ 565,795	\$ 382,224	\$ 628,468	\$ 40,169	\$ 22,644	\$ 483,321	\$ 630,936	\$ -	\$ 176,641	\$ 86,269	\$ 24,358

- Notes:
- Explanation of large capital outlays in first two years:
- Screening System: Screen in Basin 2 was out of service at the time of the Condition Assessment for major repair and received a score of 5. It has since been returned to service.

8. Connor Creek CSO Control Facility

8.1 Facility Description and Future Capacity Considerations

8.1.1 General Facility Description

The Connor Creek CSO Facility is an RTB with 30 MG of storage and a treatment capacity of 13,963 cfs. It was constructed in 2005. The facility consists of a headworks, chemical room, chemical storage area (outdoor), utility support (electrical, transformer and mechanical rooms), control room, sample room, hydraulic room, office space on the second floor, and other miscellaneous rooms.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

8.1.2 Future Capacity Considerations

There were no future capacity considerations identified at the time of this report.

8.2 Facility Assessment

8.2.1 Screening

8.2.1.1 Description of Existing System

The Connor Creek CSO Facility has 10 catenary bar screens that were installed in 2005. Channels 1-3 were originally designed to be always open (i.e., there are no influent slide gates upstream of these screens). Channels 4-10 have motorized double leaf slide type influent gates that were originally designed to open sequentially, first as a set of two (Numbers 4 and 6), and then as a final set of all remaining gates, based on increasing influent flow. During a large wet weather event in 2016, the gates did not open because there was no remote control, GLWA staff could not get to the basin, and the local area flooded. GLWA Operations decided to leave them open until all SCADA / controls can be restored for the facility.

Screenings are discharged onto one of two conveyor belts which transfer the screenings to a dumpster. One belt is provided for Bar Screens 1 through 5 and another belt is provided for Bar Screens 6 through 10. The screenings are disposed of in a landfill.

Table 8-1 provides an overview of the existing screening system at Connor Creek CSO facility.

Table 8-1. Overview of Existing Screening System at Connor Creek CSO Facility

Parameter	Value
Treatment Capacity (cfs)	13,963
No. of Screens	10
Manufacturer	US Filter
Screen Type	Catenary Bar Screen
Opening Size	1.5-in. slot
Depth or Length / Width	29 ft 8.5 in / 17 ft 0 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

8.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Investigate conveyor belt improvements to address belt alignment issues and to address occasional buildup of screenings at start of the conveyor belt incline section.

Jacobs further investigated this issue with Custom Conveyor Corporation (the original belt manufacturer). It should be noted that Custom Conveyor will conduct a site investigation at a later date during CS-299 to assess the conveyor issues and provide recommendations.

Based on initial conversations, potential recommendations to address belt alignment issues include tightening the belt tension, installing training idlers, and replacing the belt. Tightening the belt tension by adjusting the tail pulley could prevent the belt from becoming misaligned. Installing training idlers approximately every 50-ft on the carry side of the belt can prevent the belt from walking off to the side. Over time, the belt may become stretched and exceed the ability of the tail pulley to provide further tension. The belt may also reach the end of its service life. In either case, the belt may need to be replaced.

Cleats may be recommended to prevent buildup of screenings at the start of the incline. Cleats prevent screenings from sliding down the belt. Cleats may be bolted onto existing belts. Cleats requires replacing the wiper used to clean the screens with a belt thumper. The belt thumper is slave driven off the discharge pulley.

No capital improvement costs have been provided to address this issue.

- GLWA O&M personnel requested improvements to access for screen maintenance, including for wear shoes and motor and gearbox. The motor and gearbox extend over the screenings channel and are difficult to reach from the walkway next to the screen. Currently, maintenance staff use a man-basket connected to the overhead crane to access the motor.

Jacobs further investigated this issue. One option would be to construct a walkway to provide better access; however, this will likely be a costly option. This issue has been added to the list of issues to be evaluated by E&I (original screen manufacturer) during their upcoming OEM screen assessment to determine if they have a better option. The results of E&I's evaluation will help determine the scope of any improvement.

During Jacobs safety inspection under CS-299, the following issue was identified in the Headworks Building:

- Eliminate low headspace between screenings dumpsters. During Jacobs Safety Inspection in January 2020, it was noted that the support beams for the screenings conveyor create a safety hazard for staff walking through the building due to their relatively low height. These beams support the head pulleys and discharge end of the screenings conveyors.

Jacobs contacted the original conveyor manufacturer (Custom Conveyor) to evaluate options for resolving this issue. Figure 8-1 shows a recommended modification that will eliminate the overhead safety concern. It involves providing a new drive-end conveyor support for each conveyor and relocating the drive motor. This is an on-going project being completed under a JOC.

8.2.1.3 Description and Evaluation of Alternatives

The issues above are either on-going or they do not require capital improvement at this time. As such, there are no alternatives identified as screening capital improvement "needs".

Figure 8-1. Conveyer Modifications to Improve Access through Headworks Building

8.2.2 Disinfection

8.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of four outdoor insulated rubber lined steel tanks, 10 constant speed magnetic drive centrifugal pumps, 10 disinfectant rapid mix zones, and 60 induction mixers. There are 10 screens and there is one disinfectant rapid mix zone immediately downstream of each screen. There is a diffuser at floor level immediately downstream of each screen to allow feeding sodium hypochlorite before the water level reaches the low-level induction mixers and to continue to provide disinfectant near floor level throughout an event. There are six induction mixers per disinfectant rapid mix zone consisting of two low-level mixers, two mid-level mixers, and two high-level mixers. Each sodium hypochlorite pump is paired to one disinfectant rapid mix zone. However, there is a valved crossover from each pump to one other pump. This provides less redundancy than a spare pump that could serve all disinfectant rapid mix zones. The sodium hypochlorite pumps each discharge to a manifold feeding the diffuser and 6 induction mixers at their paired rapid mix zone. There is a flow meter to the diffuser and each pair of low-level, mid-level, and high-level induction mixers. Flow splitting within each pair of mixers at a given level is assumed equal based on symmetry.

Table 8-2 provides an overview of the existing disinfection system at Connor Creek CSO facility and the disinfection process flow diagram is included in Volume 6 – Appendices, Appendix G.

Table 8-2. Overview of Existing Disinfection System at Connor Creek CSO Facility

Parameter	Value
Treatment Capacity (cfs)	13,262
Design Feed Strength (% hypochlorite)	10
Max. Dosage at Design Flow (mg/L Cl ₂)	25
Disinfection Contact Time (min)	5
Storage Tanks	
Number	4
Volume of Each Tank (gal)	95,000
Type	Rubber-lined steel
Pumps	
Number	10
Capacity (gpm)	197
Type	Centrifugal, magnetic drive
Mixers	
Number / Type	60 / Chemical Induction mixers
Model Number/ hp / Manufacturer	SWC20XP / 20 hp / Water Champ

8.2.2.2 Identified Needs and Issues

The needs and issues identified for Connor Creek were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Connor Creek chemical feed system has the following issues:
 - The back-pressure valves controlling the chemical feed split between the three pairs of induction mixers and the diffuser at each disinfectant rapid mix zone are not functioning properly. Also, one

back pressure valve serves each pair of mixers at a given level. Therefore, flow splitting between each pair of mixers is assumed equal based on symmetry alone.

- The flow meters are in need of replacement due to age and some are showing significant signs of corrosion. Also, the vertical downflow orientation is poor as there is the potential for a non-full pipe.
- Similar to other facilities, it is desired to standardize on a flow splitting regime that considers such attributes as simplicity, reliability, and functionality.
- Currently, a hose must be moved and connected to each pump suction pipe to flush the hypochlorite solution from the feed system with NPW. A hard-piped flushing water connection is desired so that flushing could be accomplished by opening a valve to each pump.
- The pump area is located down four steps and there is no dedicated means to lower or lift the pumps and motors to or from this area. A mechanical means of getting pumps in and out of the room is desired.

These issues are addressed in Replace Chemical Feed System (Project CON-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project CON-DIS-2) below.
- There are 60 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project CON-DIS-3).
- Heat tracing on the outside chemical pipes occasionally fails putting the piping at risk of failing if it freezes. In fact, piping in this outdoor area for the eye wash / shower stations has previously frozen and ruptured. The heat tracing and insulation also hinders access to detect and replace leaking fittings and pipes. This issue is addressed in Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4).

8.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project CON-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, CON-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to Conner Creek feed system:

- For cost estimating purposes, water piping and valving to each feed pump was assumed to allow water flushing for the entire chemical feed system from the feed pumps to the mixers.
- For cost estimating purposes, a mast type jib crane (also referred to as a base mounted jib crane – see Figure 8-2 for an example) for moving the pumps and motors up and down the flight of stairs. The base could be located approximately 4 ft from the bottom of the stairway so as to maintain sufficient egress to and from the stairway and to provide a set down area for the pump or motor. The beam would cantilever from the base over the stairway and the upper landing. An electric hoist and trolley could then be used to pick the pump or motor, raise it, convey it over the stairway, and set it down on the upper level. From there, a cart could be used to get the pump or motor out the door. This is the recommended alternative and was used for budgeting.

Figure 8-2. Example of Mast-Type Jib Crane

The alternative evaluation for these alternatives is presented in Table 8-3. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 8-3 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 8-3. Alternative Evaluation for Replace Chemical Feed System (Project CON-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System in-kind	Health and Safety	3	2.08	\$ 2,919,000	\$ -	\$ 2,919,000	\$ 1,401,120	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with feeding too much chemical. System is unique to Conner Creek.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 5,409,000	\$ 109,670	\$ 7,721,900	\$ 2,144,972	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per disinfection channel. Utilize hose pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	LOTS of pumps and valves, allows for an installed redundant pump but manual switchover.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 2,300,000	\$ 7,000	\$ 2,447,627	\$ 679,897	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps connected to all disinfection channels. Utilize centrifugal pumps.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily utilized.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each disinfection channel.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project CON-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 8-4. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains ready for service.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 8-4. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project CON-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 156,000	\$ 4,860	\$ 258,496	\$ 74,926	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixer (Project CON-DIS-3). Plant personnel report that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. These issues are exacerbated by having 60 induction mixers at Conner Creek, which is the highest of the nine CSO facilities. A reduction in the number of mixers would reduce maintenance and the associated expense proportionate to the reduction. It would also reduce the complexity for equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4). The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** Computation fluid dynamic (CFD) modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from six to three per channel). This needs to be confirmed by collection system modeling performed by others.
- 3) **Alternative 3. Install Vertical Shaft Mixers.** This alternative would replace the existing chemical induction mixers with new vertical shaft mixers. For Conner Creek, two mixers would be provided per channel.

The alternative evaluation is presented in Table 8-5. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$18,000 per mixer.
- The capital cost for Alternative 3 (vertical shaft mixers) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 (vertical shaft mixers) are based on expected maintenance costs, including changing oil, greasing bearings, periodic rag removal from the shaft and servicing the steady bearing.

As shown in Table 8-5, Alternative 2 has a Total Benefit score about 0.4 higher than Alternative 1 because of the improved ease of maintaining fewer mixers. Alternative 3 has a Total Benefit score slightly higher than Alternative 2 based on the anticipated improved performance of the vertical mixers and improved ease of maintenance, since the mechanical portion of above the water surface. **Alternative 2, has the lowest NPV/Benefit cost and therefore, is the recommended alternative.**

It should be noted that the cost of the reduced mixers is not a new capital cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection

performance can be achieved, the vertical mixer alternative should be further explored, possibly through the pilot testing of this technology in one of the channels at Baby Creek or Conner Creek.

Table 8-5. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project CON-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace Existing Mixers in-kind	Health and Safety	3	2.57	\$ 6,000,000	\$ 438,000	\$ 15,237,260	\$ 5,936,595	
	<i>Definition:</i>	Replace existing mixers as required.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, lots of redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Expensive and impacts operations and maintenance. Equipment installed in basins.	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period	O&M Ease	1						
2	<i>Alt. Name:</i>	Model Disinfection Performance and Replace/Utilize 2/3rds of the In-Kind Mixers	Health and Safety	3	3.00	\$ 3,050,000	\$ 219,000	\$ 7,668,630	\$ 2,556,210	Best Value Alternative
	<i>Definition:</i>	Perform computational fluid dynamics (CFD) model of basin and determine required number	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, maintains required redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less expensive and less impacts to operations and maintenance. Equipment installed in	Component Performance	3						
	<i>Comments:</i>	Capital costs are based on replacement 2 times during 20-year period & CFD Modeling of \$50,000.	O&M Ease	3						
3	<i>Alt. Name:</i>	Install Vertical Shaft Mixers	Health and Safety	3	3.32	\$ 9,239,000	\$ 70,000	\$ 10,715,274	\$ 3,230,736	
	<i>Definition:</i>	Install vertical shaft mixers throughout the basin.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less equipment to operate and maintain. Overall less install horsepower. Equipment is above the basin and accessible in a non-	Capacity Enhancement	3						
	<i>Disadv.:</i>	Bearing in bottom of basin. Possible ragging issues.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4). Conner Creek is the only facility with outdoor sodium hypochlorite storage. There are two alternatives:

- 1) **Alternative 1: Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals.** Heat tracing with a monitoring system is currently used on chemical piping. Heat tracing, however, can fail and could cause the contents of an entire tank to spill into the containment area. This alternative assumes continued use of heat tracing with a monitoring system. Provisions for an improved system and, potentially replacement of the system before the end of its useful life should be considered to improve reliability.
- 2) **Alternative 2: Provide a New Building to Enclose Storage Area.** The existing structure surrounding the Chemical Storage Area consists of concrete masonry unit block wall with exterior brick. This wall is shorter than the tanks. While this wall could be integrated with a building to enclose the tanks, additional columns would be required to support the roof. A building would also require heating and ventilation, and possibly air conditioning, facility electrical (e.g., lighting and additional electrical outlets as needed), and fire protection (e.g., sprinklers). Air conditioning is often practiced with hypochlorite because the degradation rate is higher with higher temperature. Site glasses are also desired on the tanks.

For cost estimating purposes, a column supported roof and additional wall height necessary to enclose the tanks and integrate with the existing containment walls was the basis for the new structure. Provisions for HVAC, electrical and fire protection are included in the cost estimate.

The alternative evaluation is presented in Table 8-6. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 for heat trace system is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the heat trace system useful life is assumed to be 10 years. To be consistent with the building life in Alternative 2 (60 years), the cost of the heat trace system is multiplied by 5.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title. The building life is assumed to be 60 years in this analysis.

As shown in Table 8-6, Alternative 2 has a Total Benefit score about 1.2 higher than Alternative 1 because of the improved health and safety, component performance, and ease of O&M. However, the NPV/Benefit is much larger for Alternative 2 compared to Alternative. Therefore, **Alternative 1 is the recommended alternative.**

Table 8-6. Alternative Evaluation for Freeze Protection for Chemical Storage Area Piping (Project CON-DIS-4)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals	Health and Safety	2	2.40	\$ 864,000	\$ -	\$ 864,000	\$ 360,000	Best Value Alternative
	<i>Definition:</i>	Replace/upgrade existing heat trace system	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Heat tracing can fail without notice or indication, causing pipe rupture	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide a New Building to Enclose Storage Area	Health and Safety	4	3.60	\$ 3,856,000	\$ -	\$ 3,856,000	\$ 1,071,111	
	<i>Definition:</i>	Enclose area around storage tanks and piping	Water Quality & Compliance	3						
	<i>Adv.:</i>	Enclosure provides temperature-controlled space, which would prevent freezing.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.3 Odor Control

8.2.3.1 Description of Existing System

The Conner Creek odor control system consists of four dual-bed vertical carbon adsorbers, one for each retention basin compartment, located near the effluent end of the retention basin. Air is pulled from the Headworks Building, down through the floor opening in the Retention Basin, and then up through the odor control vessels at the downstream end of the retention basin. Each system treats 25,000 cfm of air. Carbon is replaced through the top and side access hatches on the vessel.

The system was installed in 2005. Overall, the system was in fair condition with two systems out of service due to fan issues at the time of the Needs Assessment.

This odor control system operates under air permit requirements (Permit to Install No. 69-06). There is no H₂S emission limit but there is a six-minute average of 20 percent opacity limit. No testing of carbon for remaining bed life is required by the permit. The carbon has not been replaced since installation.

Per GLWA, no odor complaints have been received for at least the past three years.

8.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- The odor control vessel has a dome top which increases the risk of slipping during carbon replacement.
- Jacobs odor control team notes that the majority of carbon systems are provided with simple differential pressure gauges for local monitoring. Regular monitoring of differential pressure gauges is not necessary as the pressure differential changes gradually over time and is not a critical operating parameter. SCADA monitoring is not necessary given the infrequency of operation. As such, remote monitoring of pressure drop across the carbon beds via SCADA is not recommended.
- During the site visit on 1/27/20, only Odor Control Unit 4 was in operation. The magnehelic pressure gauges showed no pressure loss through either vessel carbon bed in the dual bed vessel. The magnehelic pressure gauge across the grease filter indicated a pressure drop verifying air movement by the fan. Either the gauges are not operating, the magnehelic pressure gauge tubing is reversed, gauge ports are blocked, or there is no carbon in the vessel.

To address the lack of carbon bed pressure drop across Odor Control Unit 4, GLWA should inspect the vessel for carbon media. If the carbon media were removed at some point in the past and not replaced, there would be no pressure drop. If there is carbon in the vessel, check that the magnehelic pressure gauges are properly installed. If the gauges are installed properly, try an operating gauge from another vessel on Unit 4 to verify the pressure drop. Another possibility is the gauge ports are blocked by carbon or some component of the tank interior resin or coating. A pipe cleaner or compressed air can be used to check for blockage of the port connection and to remove loose obstructions.

8.2.3.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Access to Odor Control Vessel (Project CON-OC-1). Staff indicated that carbon replacement at the facility would require constructing scaffolding to safely access the top of the carbon vessel for replacing the top carbon bed. The vessel has a dome top increasing the risk of slipping.

Jacobs evaluated two alternatives that would make accessing the top of the carbon vessel safer for both sampling and carbon replacement.

- 1) **Alternative 1: Erect scaffolding for Carbon Replacement.** The O&M staff currently erects a scaffolding when replacing the carbon. The carbon needs to be replaced every 10 years.
- 2) **Alternative 2: Ladder and Railing System.** Figure 7-6. in the BLI facility section above shows a ladder and railing alternative. The figure does not show a 6-in. toe rail, which is recommended, that should be installed at the bottom of the railing to help prevent a person's foot from slipping off the domed top along with tools and equipment. A contractor would field install fiberglass clips and receptacles to the fiberglass tank to secure the ladder and railing. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.
- 3) **Alternative 3: Ladder, Platform and Railing System.** Figure 7-7 in the BLI facility section above shows an example of a ladder, platform, and railing on a horizontal tank. The platform provides a more stable working surface than the domed top. The option is a safer option because the platform provides a flat surface on which to stand. A contractor would field install fiberglass clips and receptacles to the fiberglass tank to secure the ladder, platform and railing. Installation of the platform and rail option is more expensive than the railing only option (Option 1) as a crane is necessary to remove the metal roof and lower the platform from above. The existing bolted hatch cover on the top of the vessel will be replaced with a hatch that has quick-opening clamps.

The alternative evaluation for these alternatives is presented in Table 8-7. The sources of costs used in this evaluation are listed below:

- The O&M cost for alternative 1 is based on \$10,000 per carbon column for erecting scaffolding. Since, the carbon is replaced once every 10 years, the annual O&M cost is assumed to be \$4,000.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C, under this project title. The standard markups for design, construction assistance and contractor overhead and profit have been applied.

This evaluation shows that Alternative 1 – Erect scaffolding for Carbon Replacement has the lowest NPV/Benefit ratio. **As such, Alternative 1 – Erect scaffolding for Carbon Replacement is the recommended alternative.**

Table 8-7. Alternative Evaluation for Access to Odor Control Vessel (Project CON-OC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Erect Scaffolding for Carbon Replacement	Health and Safety	2	2.50	\$ -	\$ 4,000	\$ 84,359	\$ 33,743	Best Value Alternative
	<i>Definition:</i>	Continue to use scaffolding when replacing carbon.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Must be set up every time carbon is replaced.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Ladder and Railing System	Health and Safety	3	3.22	\$ 138,000	\$ -	\$ 138,000	\$ 42,902	
	<i>Definition:</i>	Provide a ladder on side of vessel and railing around top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Ladder provides improved access and railing provides safety during carbon change-out.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Surface of dome is still sloped and not as safe as a flat surface.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Ladder, Platform, and Railing System	Health and Safety	5	4.00	\$ 410,000	\$ -	\$ 410,000	\$ 102,500	
	<i>Definition:</i>	Provide a ladder on side of vessel and a platform and railing system on top of vessel.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Platform provides more stable working surface of top of vessel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

8.2.4 Flushing and Dewatering

8.2.4.1 Description of Existing System

Dewatering System: The basin and upstream hydraulic structures are dewatered mostly by gravity. Four submersible dewatering pumps located in a sump area in the central portion of the CSO basin (between Compartments 2 and 3) are used when gravity flow rates decline below pumping rate. The total volume of stored CSO after an overflow event is 62 MG, with 30 MG in the basin and 32 MG in the upstream structures. The volume of 62 MG was designed to be dewatered to the DRI in a 48-hour period. The rate of dewatering is controlled based on the level in the DRI.

Each pump discharges through a dedicated pipe to a junction chamber located next to the basin. All four pumps are intended to operate simultaneously. If one of the dewatering pumps is out of service, a flushing pump can be put into service.

Flushing System: A flushing gate system is used for cleaning solids from the bottom of the basin. Flushing gates with reservoirs were constructed at the following locations: 1) at each side of the screening distribution channel (upstream of the screens); 2) at each side of the basin distribution channel (i.e., the channel downstream of the screens); and 3) at the influent and effluent ends of the four basin compartments. The flushing reservoirs fill with wastewater as the facility fills during a wet weather event. Once the facility is dewatered, water remains in the reservoir. When the flushing gates are actuated, a surge of water is discharged down the channel, scouring solids and moving them into the sump areas. Flushing solids pumps are used to pump this water and solids mixture to the DRI. See Table 8-8 for the location and capacity of the pumps. If additional flushing is needed after the initial flush, NPW can be used to re-fill the reservoir.

The facility receives a significant amount of grit and large debris from the collection system. Because of the large accumulation of grit and heavy solids in the Screening Distribution Channel (upstream of the screens), the flushing gates and flushed solids pump (FSP-1) are ineffective in this area. In fact, FSP-1 has been removed and GLWA staff must use water hoses, vactor truck hoses and portable pumps to remove the solids from this channel.

For the influent sewer area ahead of the Screening Distribution Channel, a bobcat is lowered through a hatch to aid in moving the solids to the hatch area for subsequent removal. Solids are typically loaded into a small container to be lifted out through the hatch and loaded into a larger dumpster at ground level.

Table 8-8 provides an overview of the existing flushing and dewatering system at Connor Creek CSO facility.

Table 8-8. Overview of Existing Flushing and Dewatering System at Connor Creek CSO Facility

Parameter	Value
Total Basin Volume (MG)	30
Headworks and Basin Dewatering and Flushing System	- Flushing gates are installed in 1) Screening Distribution Channel; 2) Basin Distribution Channel; 3) Each Basin Compartment (4 total) 8 flushing gates for each channel or compartment (48 total) - FSPs are used to remove flushed solids from each compartment. - FSP-1 in the area ahead of the screens has been removed due to excessively high grit levels - FSP-2 in the Basin Distribution Channel is 735 gpm at 39.8 ft TDH - FSP-3 and 4 in the middle of the basins are 1,610 gpm at 51.5 TDH - Gravity dewatering can occur down to about 84 ft via in-system storage gates. - Four dewatering pumps. Capacity varies with water level in basin from 7,600 gpm at 12.3 ft TDH (basin full) to 4,475 gpm at 45.5 ft TDH (basin empty). Flow is routed to the DRI

Note:

TDH = total dynamic head

8.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- A significant amount of solids builds up in the Screening Distribution Channel (upstream of the screens). The removal of solids is labor intensive and costly, and some areas are inaccessible to the bobcat.
- Filling the flushing reservoirs after the first flush uses a significant amount of potable water, which is costly, and is a time consuming exercise. Also, water fills a group of four reservoirs by filling one reservoir and subsequently overflowing into the next three, one at a time. If one of the first flushing gates leaks, the downstream reservoirs do not get filled.
- Accumulation of sediment within the Conner Creek channel could potentially limit the discharge capacity of the facility.
- Many flushing gates do not function properly. Based on an inspection of each flushing gate in late 2019/early 2020 by a contractor, many of the gates do not function properly, making cleaning the basin difficult, if not completely ineffective, and time-consuming. GLWA is currently addressing this issue through rehabilitation of the existing gates through a JOC. As such, this project is not included in the capital improvement projects under CS-299.

8.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screening Distribution Channel Improvements (Project CON-FD-1). A significant amount of grit builds up in the influent conduits to the Conner Creek Basin and in the Screening Distribution Channel. The build-up of solids (typically 3 to 6 ft high over time) prevents the flushing gates in the Screening Distribution Channel from being able to flush the solids to the sump area and it has overwhelmed FSP-1. Due to the significant quantity of grit, considerations to improve or modify the existing grit removal system were quickly dismissed.

The most effective method of grit removal for this CSO facility has proven to be using a bobcat to load the grit into dumpsters. In 2017, GLWA added a large (8-ft × 12-ft) equipment hatch to the influent conduit area to lower a bobcat into this area. This opening is also used to remove the grit from influent conduit area using a small container and dumping it into a larger dumpster located at the surface.

The flushing channels cannot be cleaned out by a bobcat since the channels are not accessible. To make them accessible, the leading alternative is to remove the training walls of the flushing channels, install ramps for the bobcat to access the channel area and fill the FSP-1 area with concrete. This concept is shown in several figures (Figure CON-FD-1-ALT-2) in Volume 6 – Appendices, Appendix B, and described further below.

There are two alternatives for addressing this issue:

1) **Alternative 1: Do Nothing/ Continue to Manually Clean Area**

2) **Alternative 2: Screening Distribution Channel Improvements.** This alternative includes the following:

Demolition of existing concrete and equipment. The recommended improvement involves demolition of the existing flushing gate channel training walls, flushing gate assemblies, and the front flushing gate reservoir walls. The anticipated demolition method is jackhammering, which will remove the concrete down to below the adjacent floor system. Rebar will be cut below the floor surface as well. High-strength concrete patching materials will be applied to create an overall smooth surface on the flushing floor. By removing this concrete, O&M staff will be able to maneuver around the area freely to collect sediment

Concrete Fill. The flushing wave collection channel will be filled in with concrete to be level with the floor surface. The FSP-1 sump will be cleaned and partially filled with concrete to result in a shallower sump, approximately 2 ft below the flushing floor edge.

Drain Pump System Reconfiguration and Reinstallation. The FSP-1 sump pump was previously removed by GLWA due to consistent pump fouling by sediment. Jacobs recommends constructing a more robust screen around the FSP-1 sump and reinstalling the pump and discharge piping. The benefit of reinstalling a protected pump is the ability to consistently dewater the influent channel area after all events, and to dewater the space more effectively prior to grit removal.

The more robust sump pump screen concept consists of a static screen installed around the existing sump. Four 6-in. bollards will be set inside the FSP-1 sump prior to concrete filling. A stainless-steel perforated screen will be fabricated with 2-mm openings (similar material and opening size to screens used for dewatering sumps in construction excavations). The screen fabrication will be approximately 10 ft high and will be positioned over the bollards, with the bollards serving to maintain the screen in its location. The screen unit will be sufficiently heavy to remain in place during inundation by CSO events but can be lifted from the surface to a height necessary to clean any debris that may accumulate inside the screen.

The FSP-1 sump pump will be reconfigured such that the pump suction intake is 2 ft above the sump floor with a welded stainless steel bracket. The operational setting for this pump will be reprogrammed to start operation once the minimum pump submergence level has been detected (requires level sensor element control) and will stay in operation for the duration of the event. A provision for a secondary water jet should be provided at the intake to support the dewatering. With the perforated screen in place, and the pump in continuous operation, the sediment loading inside the screened area will be significantly minimized, allowing the influent channel to be adequately dewatered following each event. The perforated screen can be lifted from the surface if needed to access the sump area.

Access to Screening Distribution Floor. To facilitate access to the floor from the influent conduit access hatch, two concrete ramps will be poured with a 12H:1V slope (approximately 8 degrees). Concrete bollards (6-in. diameter, 4 ft tall) will be set along the edge of the upper level at 6-foot spacings and along the edge of the ramp to the cleaning floor, effectively guiding equipment operators to the ramp during sediment removal and preventing driving over the edge.

At-Surface Sediment Removal. To support a more efficient removal of sediment from the area upstream of the bar screens, a series of 8 ft × 8 ft openings will be cut into the influent channel roof. A surface mounted conveyor unit will be extended into the opening down to the floor, where the bobcat operator can deposit sediment in a hopper. See Figure 8-3 for an example of a conveyor that could be used. The conveyor will lift the sediment to the surface and deposit the material into a dumpster or directly to a dump truck for off-site disposal. As the operator systematically cleans the area, the conveyor can be rotated to different positions using a crane from the surface as needed to minimize bobcat travel. Once a general area has been cleaned, the conveyor is retracted and relocated to another opening. The sequence is repeated until the entire upper level and floor has been adequately cleaned. Additionally, the openings through the roof slab facilitate easier access to the influent channel during construction. The conveyor used as a basis of the concept can be viewed online at www.interquip.net. When not in use, the conveyor belt unit would be disassembled and stored onsite. GLWA staff will need to identify a potential location where the stored unit does not interfere with day-to-day O&M. A covered storage structure (e.g., canopy cover, prefabricated metal shelter) and paved surfacing at a preferred storage location is not included in the capital cost estimate.

Figure 8-3. Example of Surface Mounted Conveyor Unit

Flow management during construction will be a major consideration for this option. Bypass pumping is not feasible, given the potentially large flows and isolating the areas of concrete addition will not be cost effective. Constructing concrete sections for the channel infill and the two concrete ramps above-ground and lowering into place should be considered. This issue will require much further evaluation during detailed design.

New Storage Building. A new 30-ft by 60-ft prefabricated metal building with a concrete slab-on-grade will be constructed near the existing building. The building will be used to store the conveyor, stop logs, and other spare parts for the facility.

The alternative evaluation for these alternatives is presented in Table 8-9. The sources of costs used in this evaluation are listed below:

- The O&M cost for Alternative 1 includes GLWA labor cost and water usage cost. The labor cost is based on 3 staff for 80 hours per week and 4 times per year, or about \$100,000 per year. Water usage assumes a water jet is needed to break-up the solids and convey them to the sump area. Water usage based on about 1 MGD needed for 8 hours per day during the 2 week period at \$4,000/MG, or about \$56,000 per year.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$200,000 for cleaning/re-cleaning the Screening area, and another \$200,000 allowance for wet weather interruptions/delays.
- The O&M costs for Alternative 2 is based on GLWA labor cost of 2 staff for 20 hours per week and 8 times per year, or about \$16,000 per year.
- Grit disposal costs are assumed to be similar for the two alternatives and, therefore, not included.

This evaluation shows that the Total Benefit score for Alternative 2 is 2.0 higher than Alternative 1 because of improved health and safety and ease of O&M. In addition, it is the best value alternative. **As such, Alternative 2 – Screening Distribution Channel Improvements is the recommended alternative.**

Table 8-9. Alternative Evaluation for Screening Distribution Channel Solids Build-Up (Project CON-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	1	1.72	\$ -	\$ 156,000	\$ 3,289,983	\$ 1,916,495	
	<i>Definition:</i>	Continue removing solids from portion of basin using bobcat and bucket	Water Quality & Compliance	2						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Labor intensive, solids typically remain due to incomplete cleaning - thus solids could be scoured out of basin in a subsequent storm.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Screening Distribution Channel Improvements	Health and Safety	4	3.72	\$ 2,880,000	\$ 16,000	\$ 3,217,434	\$ 865,677	Best Value Alternative
	<i>Definition:</i>	Modify floor of channel to remove training walls and add ramps for bobcat; fill flushing wave collection channel with concrete; reconfigure and reinstall Flushing Solids Pump 1; provide removable solids removal conveyor.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Will make solids removal less labor intensive, less costly and safer.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

Flushing Water System Improvements (Project CON-FD-2). The flushing reservoirs in the basin and influent area are naturally filled with combined sewage during storms that fill at least one-quarter of the basin. The volume of water captured in the flushing reservoirs is used to flush the settled debris from the floor of the basin. If additional flushing is needed, NPW (i.e., City water that has gone through the backflow preventer) must be used. GLWA Operations personnel have noted that it takes about 10 hours to fill all the flushing reservoirs with water using the water lines. Based on the active reservoir volume of 0.4 MG, this implies that the average flow rate is about 700 gpm. Operations personnel also note that there is a drop in water pressure for hose washdown in the basin when the flushing reservoirs are being filled. The reservoir fill lines and hose drop connections are fed from the same service water system in the basin. The header for this system is an 8-in. diameter water line. The basin flushing water is fed from the facility's service water system that originates from a 12-in. connection on Freud Avenue.

There are three alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Continue Using Potable Water**
- 2) **Alternative 2: Flushing Water System Improvements Using River Water.** This alternative involves using water from Conner Creek for flushing water. The gravity-fed system would consist of two 12-in. HDPE header pipes located across the basin to service the flushing reservoirs. See figures (Figure CON-FD-2-ALT-2) in Volume 6 – Appendices, Appendix B, for a plan view and section view, respectively, of this option. Each header would originate on the east side of the basin in the canal where the pipe would penetrate the basin wall. A screen (manually cleaned) is shown at the inlet of each pipe to prevent large objects from entering the header pipe. Platforms are provided at each inlet to allow for cleaning the screen, if necessary. The installation of this system will require intake structures, along with accompanying cofferdams, to be constructed at each intake into the basin from the canal.

The screened inlet must be located at an elevation below the Detroit River low water datum, which is approximately elevation 93.0 ft (City of Detroit Datum). At this river elevation, there would be a minimum of 12 ft of static head between the river elevation and the elevation of the discharge points at the flushing reservoirs. A motorized control valve would be located on the header pipe at each set of flushing reservoirs. After each valve, GLWA has requested piping to each individual reservoir, which allows for filling each reservoir even when there is a leak (i.e., a leak at the flushing gate) in the first reservoir. It is anticipated that each header could convey approximately 2,000 gpm, or nearly 3 million gallons per day (MGD). The influent and effluent flushing reservoirs could be filled independently. This modification, along with higher flows, would significantly reduce the time to fill the reservoirs.

The advantages of this gravity system, compared to a pumping system, are:

- City water savings (see alternative evaluation for details)
- Few moving parts to be maintained
- Lower maintenance cost
- Lower capital cost
- Ability to fill influent-end and effluent-end flushing reservoirs at the same time, thus significantly reducing the time to fill the reservoirs
- Ability to fill four reservoirs at a time, instead of filling one reservoir and allowing the water to overflow into subsequent reservoirs, by using a valve to control flow to the group of four reservoirs and extending a pipe with discharge to each of the four reservoirs.

The disadvantages of the gravity system, compared to a pumping system, are:

- Valve actuator being at the deck level will have 25 to 30 ft long stem requiring several braces spaced along the height of the valve stems.

- Potential blockage of screens due to zebra mussels

The attachment of zebra mussels on the intake screen or in the intake pipe will decrease screen inlet flow area and pipe diameter reducing flushing reservoir filling rates or completely restricting flows to the individual flushing reservoirs. Allowing zebra mussels to colonize the intake pipes will also provide them with an opportunity to enter the basin where further colonization may occur. For these reasons, it is recommended that a zebra mussel control strategy be implemented at each of the intake pipe locations for the gravity-feed system. There are a variety of mussel control measures ranging from treatments with chlorine and other oxidants, mechanical removal, and special pipe coatings. Sodium hypochlorite is commonly used to control zebra mussel growth. Extension of the Conner Creek CSO hypochlorite system to the raw water inlets may be the simplest approach as hypochlorite does not need to be applied continuously. Intermittent application of 1.0 mg/L hypochlorite during the breeding season in the summer is usually sufficient. Many utilities apply hypochlorite to the front edge of water intake pipes to prevent mussel colonization and to kill any mussels that have already attached. GLWA currently applies hypochlorite at the Belle Isle intake structure to control zebra mussels on the intake screens and within the intake structure and tunnel. Such practices are therefore recommended at the respective intake areas at the Connor Creek facility.

It should be noted that an application for water withdrawal from EGLE in excess of 2 MGD is required. The need for this permit will need to be further explored during detailed design phase. Water is not being diverted from the Great Lakes basin so obtaining a permit should not be a problem.

- 3) **Alternative 3: Flushing Water System Improvements Using Potable Water.** This alternative involves continued use of City water from Conner Creek, with the addition of the valves and piping to allow the groups of four reservoirs to fill at one time, as described in Alternative 2. Instead of tying into the river water piping, this proposed system would tie into the existing potable water system.

This alternative would have the advantage of being able to fill reservoirs downstream of leaking flushing gates. It would have the disadvantage of using a significant amount of City water and would still take a long time to fill all the reservoirs with water.

The alternative evaluation for these alternatives is presented in Table 8-10. The sources of costs used in this evaluation are listed below:

- The annual O&M cost for Alternative 1 and 3 is based on water usage of 800,000 gallons per event, 25 events a year, and a unit cost of \$4,000 per MG. The annualized cost of water is about \$80,000.
- The capital cost for the proposed flushing systems (Alternatives 2 and 3) are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 2 includes \$2,000 for equipment maintenance.

This evaluation shows that Alternative 1 – Do Nothing/Continue Using Potable Water, is the best value alternative. However, this alternative does not provide an acceptable level of cleaning when there are leaking flushing gates. Alternative 2 and 3 provides a solution to this issue. The NPV/Benefit cost for Alternative 3 is greater than Alternative 2. Because Alternative 2 provides the best value alternative compared to Alternative 3, **Alternative 2 – Flushing Water System Improvements Using River Water is the recommended alternative.**

Table 8-10. Alternative Evaluation for Flushing Water System Improvements (Project CON-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Continue Using Potable Water	Health and Safety	3	2.68	\$ -	\$ 80,000	\$ 1,687,171	\$ 628,759	Best Value Alternative
	<i>Definition:</i>	Continue to use potable water to fill reservoirs	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Significant amount of City water usage; time consuming	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Flushing Water System Improvements Using River Water	Health and Safety	3	3.32	\$ 2,692,000	\$ 2,000	\$ 2,734,179	\$ 824,376	
	<i>Definition:</i>	Use river water as source of flushing water	Water Quality & Compliance	3						
	<i>Adv.:</i>	Reduced potable water usage/cost; less time to fill reservoirs; lower maintenance cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Zebra mussel control	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Flushing Water System Improvements Using Potable Water	Health and Safety	3	3.32	\$ 1,332,000	\$ 80,000	\$ 3,019,171	\$ 910,303	
	<i>Definition:</i>	Continue to use potable water to fill reservoirs; add distribution to each reservoir	Water Quality & Compliance	3						
	<i>Adv.:</i>	All reservoirs can be filled even if there is a damaged gate	Capacity Enhancement	3						
	<i>Disadv.:</i>	Significant amount of City water usage; long time to fill reservoirs	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.5 HVAC

8.2.5.1 Description of Existing System

The Conner Creek CSO Facility consists of a Headworks, chemical room, chemical storage area (outdoor), utility support (electrical, transformer and mechanical rooms), control room, sample room, hydraulic room, office space on the second floor, and other miscellaneous rooms. The facility also includes adjoining retention basin. Table 8-11 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, gas-heater water heater, electric water coolers, emergency shower/eye wash, and washroom shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 8.2.10.

Table 8-11. Major HVAC Equipment at Connor Creek CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	MAU-1 and 2	2 × Make-Up Air Units	44,000 CFM
Basin	ICEF-1 to 6	6 × Exhaust Fan (Influent Area)	50,200 CFM
	SF-1 to 24	24 × Supply Fan (Basin Deck)	45,000 CFM
Control Building	AHU-1	Air Handler	21,000 CFM
Chemical Room	EF-3	Exhaust Fan	4,140 CFM
	AHU-2	Air Handler	4,080 CFM
Electrical Room	EF-5	Exhaust Fan	2,893 CFM
	EUH-2	Electric Unit Heater	10.2 MBtu
Transformer Room	EF-4	Exhaust Fan	3,130 CFM

Note:

MBtu = million British thermal unit(s)

Table 8-12 provides a summary of the basis of design performance criteria for HVAC systems at Connor Creek and Table 8-13 provides the outdoor Basis of Design conditions.

Table 8-12. Connor Creek Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks Building	Class I, Div 1, Group D (Per Basis of Design Report)	60	N/A	12 ACH (Occupied) 6 ACH (Unoccupied)
Mechanical and Electrical Rooms, Transformer Room, and Maintenance Shop	Unclassified	60	104	Heat Relief
Control Room	Unclassified	72 F Dry Bulb, 50% Relative Humidity	72 F Dry Bulb, 50% Relative Humidity	20 cfm per occupant
Office, Sample Room, Toilet Rooms and Hydraulic Room	Unclassified	72 (Occupied), 60 (Unoccupied)	75 F Dry Bulb, 50% Relative Humidity	50 cfm per flushing fixture (restrooms)

8.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- Inadequate heating in maintenance shop and electrical room: O&M staff noted that the Maintenance Shop gets cold in winter months and electrical room to a lesser degree.
- Uneven heating was reported in the Control Building
- High temperatures in transformer room: Based on investigation by Jacobs, the basis of design summer dry bulb temperature for transformer room is 104°F. It is therefore not unusual that relatively high temperatures are observed in this space. During the site visit by Jacobs, exceedingly high temperatures were not noted in the transformer room; however, the door to the transformer room was open and the exhaust fan was observed to run at a low rpms, likely indicating a reduced airflow capacity. Additionally, the thermostat did not appear to be functional based on the fact that the exhaust fan remained on and the supply air damper remained open when the thermostat was adjusted to a setpoint above the space temperature. This is not considered a capital need.
- GLWA staff reported malfunctioning dampers in chemical room, maintenance room, electrical room, and transformer room. During the Jacobs site visit, the Maintenance Shop and electrical room motorized dampers were tested for functionality. The dampers responded to changes in the thermostat setpoint; however, there was a delay in the response. This delay is normal and does not require any corrective actions. The transformer room damper was observed to be open and the exhaust fan running; however, the damper and fan did not respond to changes in the thermostat setpoint. This issue should be investigated and corrected by maintenance staff and is not considered a capital need.
- Chemical room AHU-2 is difficult to replace due to limited size of door openings to the chemical room.
- O&M staff would like a shower in the upstairs men's and women's restrooms.

During the discussions with Dunbar Mechanical, GLWA's HVAC contractor, the following historical issues were noted:

- Heating Improvements in Control Building: GLWA's HVAC contractor noted that on/off control from the duct heaters in the Control Building was replaced with a controller that modulates the gas valves to maintain a minimum supply air temperature.
- Replacement of Duct Heater: GLWA's HVAC contractor noted that one of the three gas duct heaters had been recently replaced.

- Humidity Issues in exterior rooms: GLWA's HVAC contractor noted that major humidity issues had occurred in the North and East exterior room in the Control Building. Jacobs notes that several factors could be contributing to the humidity issues noted by GLWA's HVAC contractor. Major contributors include:
 - Insufficient cooling capacity of AHU-1's cooling coil. As noted below, the McQuay condensing unit appears to have a refrigerant leak which would result in a decrease in the ability of AHU-1 to remove humidity from the incoming outside air and return air streams. The recommended replacement of the condensing unit should eliminate cooling capacity as a contributing factor to high humidity levels.
 - Air infiltration into the space. During the site walkthrough it was noted that windows were left open in the Conference Area on the 2nd floor. Major sources of infiltration such as open windows would seriously contribute to the potential for condensation in air-conditioned spaces, particularly in the summer when the outside air dewpoint temperature is likely to be above the dewpoint temperature of interior surfaces.
 - Insufficient ventilation/poor air distribution (which would allow for the buildup of humidity in occupied spaces). The uneven heating noted by GLWA O&M staff could be an indicator of poor air distribution/ventilation. The recommended air balance should eliminate this as a potential contributing factor.

If the humidity issues persist after the recommended air balance study and replacement of the condensing unit, monitoring of the doors and windows using the direct digital controller (DDC) could be considered to determine if there is a correlation between open windows/doors and humidity issues.

During site investigations (June 2020) the following observations were noted:

- A new split DX system had recently been installed in the control room server area.
- The windows were open in the control building second floor conference room.
- The exhaust fan was off in the chemical room.
- Both roll-up doors were open in the headworks area.
- Oil was observed on the McQuay air-cooled condensing unit's (ACCU-1) condensing coil and the compressors were observed to be hissing (see Figure 8-4 below). This observation most likely indicates a refrigerant leak. The unit is 17-years old and a refrigerant leak would result in reduced cooling capacity, which could be contributing to the humidity issues in the control room noted by GLWA's HVAC contractor. Given that the unit is near the end of its useful life and a refrigerant leak is likely, it is recommended that the unit be replaced with a unit of the same capacity and added to the DDC system for monitoring and control. This replacement is included in the SRP.

Figure 8-4. Oil on McQuay Unit Condensing Coil

- The door to the transformer room was open.
- The transformer room exhaust fan appeared to be operating at low RPM.
- The actuator on the transformer room motorized damper appeared to have been recently installed.
- The electrical room overhead door was open.
- The electrical room exhaust fan intake is located very close to the air intake louver with motorized damper.
- The Maintenance Shop exhaust air ductwork is located close to its air intake louver.
- The duct for Basin supply fan SF-22 (located in the Maintenance Shop) is not enclosed in fire-rated walls as indicated on the design drawings (see Figure 8-5 and Figure 8-6).

Figure 8-5. Supply Duct for SF-22 Not Enclosed in Fire-Rated Wall

Figure 8-6. SF-22 Chase Detail (Per 02/06 Project Record Drawings)

8.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Control Building Air Balance Study. As noted in Section 8.2.5.2, the duct heaters in the Control Building have recently had a control upgrade to modulate the gas valves and maintain a minimum discharge temperature instead of being on-off and controlled by wall-mounted thermostats. If this change has not resolved the uneven heating experienced in the Control Building, an air balance study is recommended to determine if heated air is properly being distributed to spaces in the Control Building. If this does not resolve the issues, additional measures can be considered, such as additional duct heaters in spaces which are receiving inadequate heat. Jacobs recently prepared a scope to coordinate air balance study with a Testing and Air Balancing contractor.

HVAC Improvements (Project CON-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: HVAC Improvements** including,

- Maintenance Shop and Electrical Room Heating Improvements
- Chemical Room AHU Access Improvements
- Control Room Wall Extension
- Chase for SF-22 Basin Supply Air Duct
- Shower in Second Floor Men's and Women's Restrooms

Each of the HVAC related improvements listed above are described further below:

Maintenance Shop and Electrical Room Heating Improvements. The basis of design winter dry bulb temperature for the Maintenance Shop and electrical room is 60°F so it is possible that these areas could be perceived as being cold in the winter. Both the Maintenance Shop and electrical room are served by a single 3 kW electric unit heater. Jacobs noted that the unit heater in the Maintenance Shop and electrical room are located on the opposite side of the room from the outside doors, which likely makes for a big difference in temperature across the room during the winter months. It is recommended that an additional unit heater be added to each room.

Chemical Room AHU Access Improvements. To improve ability to remove this unit in the future, the single door to the hallway should be replaced with a double door.

Control Room Wall Extension. A new split DX system was recently added to the control room server area. This space is provided with conditioned air from AHU-1 and is not completely enclosed with a floor to ceiling partition (Figure 8-7). Thermal comfort in the occupied portion of the control room would be improved by extending the existing partition between the two spaces to the ceiling and extending the existing return air duct to the server room area in an appropriate location.

Figure 8-7. Low Wall in Control Room

Chase for SF-22 Basin Supply Air Duct. Per the design drawings, the supply air duct for SF-22 which runs through the Maintenance Shop to the Basin below was designed to be enclosed in a chase, which would create a physical separation between the Maintenance Shop and the supply air duct. A similar chase was constructed in the transformer room for SF-21's supply air ductwork. NFPA 820 requires a gas tight partition between classified spaces (such as the Basin, which is Class I, Division 1) and unclassified spaces, which was the reason the original design included the chase. Without the enclosure for the supply air duct, the Maintenance Shop, and by extension all spaces connected to it, are technically Class I, Division 1 spaces. It is recommended that a

chase be constructed in the Maintenance Shop per the original design drawings to create the required physical separation between the Basin and Maintenance Shop. See Figure 8-6 herein.

Shower in 2nd Floor Men's and Women's Restrooms. Space exists for the installation of showers in the 2nd Floor Washrooms. Although a complete design would require further assessment it seems likely that the drains, vents, and hot and cold water supplies could be connected to the existing plumbing system fairly easily.

During the evaluation of the existing plumbing assets it was discovered that the existing hot water tank only has a 100-gallon capacity. ANSI Z358.1 requires 20 gpm of tepid water for a period of 15 minutes for emergency showers. At the design mixed water temperature of 80°F, design storage temperature of 120°F, and recommended 47°F cold water design inlet temperature, the existing tank would only provide tepid water for 11 minutes. Jacobs recommends that the hot water tank should be replaced with one with a storage capacity of at least 150 gallons regardless of whether the shower upgrades are pursued.

The alternative evaluation is presented in Table 8-14. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- There is no measurable difference in O&M costs between the two alternatives.

This evaluation shows that Alternative 1 is the Best Value Alternative. Under Alternative 2, the chase for SF-22 air duct is a code compliance issue, so it should be implemented during a major project at the facility. Based on this need, **Alternative 2 is the recommended alternative.** However, it is noted that the remaining tasks are not high priority and could be performed at a later date.

Table 8-14. Alternative Evaluation for HVAC Improvements (Project CON-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	4						

8.2.6 Electrical

8.2.6.1 Description of Existing System

The Conner Creek facility's electrical system consists of dual (redundant) 24 kV utility feeds for two unit substations with primary metering and DTE 3,000 kVA indoor dry type transformers. The facility also has one diesel generator feed from a 2 MW, 480/277 V, 3-phase stationary generator. The substations and generator feed into the double ended switchboard main distribution panel (MDP), which has a tie-breaker and automatic source transfer controls. Circuit breakers in the MDP then feed six MCCs and one power distribution panel (PDP). The MCCs and PDP then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 8-15 provides a summary of the major electrical equipment for this facility.

Table 8-15. Major Electrical Equipment at Connor Creek

Location	Major Electrical Equipment	Description
Transformers Room	Transformers T1 and T2 Substations	3,000 kVA, 24 kV-480/277 V, 3-Phase
Outdoors	Generator (Diesel)	2 MW, 480/277 V, 3-Phase
Electrical Room	Double ended switchboard main distribution panel (MDP)	3,200 A, 480/277 V, 3-Phase
Electrical Room	MCC-1	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-3	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-4	1,600 A, 480/277 V, 3-Phase
Electrical Room	MCC-5	1,600 A, 480/277 V, 3-Phase
Chemical Room	MCC-6	1,600 A, 480/277 V, 3-Phase

8.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

8.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project CON-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating at night and select locations within the basin.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure CON-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - FSP-2 access stairway – Relocate the existing LED wall mounted light fixtures to provide the required foot-candles and code requirements.

- Influent area ahead of Screens – Add LED lighting fixtures to meet the required foot-candles and code requirements for the area.
- Interior effluent end of Basin – Add interior LED wall mounted lighting fixtures to the area to address the required foot-candles and code requirement.
- Exterior effluent end of Basin – Add additional exterior LED lighting fixtures to supplement the current lighting within the area to address the required foot-candles and code requirements.
- Add power receptacles to assist in the maintenance and operations of the facility near the FSP-1 opening.

The alternative evaluation is presented in Table 8-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting. The NPV/Benefit cost for Alternative 2 is \$37,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 8-16. Alternative Evaluation for Electrical Improvements (Project CON-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night and select locations within the basin	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 129,000	\$ -	\$ 129,000	\$ 36,857	Not Applicable
	<i>Definition:</i>	Add additional lighting in the at select locations in the basin and near the effluent.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.7 I&C

8.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2005 under GLWA project PC-739. During the same time period, stand-alone Ovation systems were being installed in the Freud Pump Station and Conner Creek Pump Station under PC-713. The Conner Creek CSO facility was designed to house the main control system for the region. In 2014 under PC-773D, the three facilities were combined into one overall Ovation control system. While the systems were being combined, the system controllers and software were upgraded to version O.V.3.5.0 for all three facilities.

The Conner Creek control system is comprised of primary and back-up network switches to provide the system complete network redundancy. The switches are connected to the GLWA AT&T wide area network via the system's router. These primary and back-up network switches are interfaced to three redundant networks, with one at the Freud Pump Station, one at the Conner Creek CSO facility, and one at the Conner Pump Station. The redundant network switches in the Conner CSO facility are connected to one database server and two operator workstations. All workstations are connected redundantly to the network switches via copper Ethernet cables. Additionally, it has two redundant Ovation controllers connected to the network switches in a dual-homed configuration to provide back-up for controls and I/O capabilities. The current system is equipped with a back-up radio system to communicate critical monitoring points back to SCC on wide area network failure.

The Freud Pump Station has redundant network switches connected to Conner Creek's main control systems primary and back-up network switches in the Conner Creek CSO facility. The networks are connected via fiber optic cables in underground ductbanks between the two facilities. There is a rack mounted workstation and one redundant Ovation controller pair for the station. The Ovation controllers and the workstation are connected in a dual-homed configuration via copper Ethernet cables. Additional local PLCs are connected to the Ovation control system via local system switches.

The Conner Pump Station has redundant network switches connected to Conner Creek's main control system primary and back-up network switches in the Conner Creek CSO facility, similar to the Freud Pump Station. The networks are connected via fiber optic cables in underground ductbanks between the two facilities. There is a rack mounted workstation and one redundant Ovation controller pair for the station. The Ovation controllers and the workstation are connected in a dual-homed configuration via copper Ethernet cables. Additional local PLCs are connected to the Ovation control system via local system switches.

Flow and Level Sensors: Table 8-17 summarizes the level sensors and flow meters at the Conner Creek CSO Facility used to monitor flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 8-17. Summary of Flow Meters and Level Sensors at Connor Creek CSO Facility

Area	Quantity	Instrument Type
CSO Influent Flow Meters		
Influent (East, central, and west influent channel flow, Freud Ashland Relief, Freud Fox Creek Relief)	5	Transit-Time (AccuSonic)
CSO Facility Level Sensors		
Mixing Chambers	2	Ultrasonic
	10	Ultrasonic (back-up)

Area	Quantity	Instrument Type
Flushed Solids Sumps (Dewatering sumps (2), Retention Basin Distribution Channel, Screening Distribution Dchannel)	4	Ultrasonic
Conner Creek	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed Pumps	10	Magnetic
Chemical Mixers and Diffusers		
High Mixers	10	Magnetic
Middle Mixers	10	
Low Mixers	10	
Diffusers	10	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	4	Ultrasonic

8.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section .

- Evaluate the existing level sensors and flow meters to determine redundancy and identify instruments that could potentially be removed. The evaluation and recommended removal of level sensors is presented in the next section.
- Operators have no way to determine whether the dewatering pumps are functioning properly. To address this issue, they requested a new flow meter downstream of the junction chamber to provide indication and rate of flow.
- Evaluate replacement options for valve control network
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system to the latest version and increased monitoring capabilities
- Generator and ATS controls do not adequately report alarm signals into Ovation and are becoming less reliable. This issue is being addressed in an on-going project and is therefore not included in the capital improvement projects for CS-299.
- Need accurate river level measurement. GLWA is currently planning to install a river level sensor through a JOC. This issue is not included in the capital improvement projects for CS-299.

8.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project CON-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation control system upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) Alternative 1: Do Nothing/Replace In-Kind.

- Leave level sensors in place

2) Alternative 2: I&C Improvements including,

- Remove redundant level sensors
- Provide new flow meter for dewatering flow downstream of the junction chamber
- Evaluate replacement options for valve control network
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Remove redundant level sensors. The Conner Creek CSO Facility has 12 level sensors in the chemical mixing chambers downstream of the screens. There are two primary ultrasonic level sensors, one in Mixing Chamber 3 and one in Mixing Chamber 8, and a level sensor in each of the ten chemical mixing chambers. See Figure 8-8 for the location of these sensors.

The level sensor signals are used to turn on and off the lower, middle and upper level mixers based on the water level in the channels. Since all the channels are interconnected downstream of the screens, the water level should be fairly similar between the mixing channels. The readouts for the individual channel level sensors are not available on the Ovation screens. However, while these level sensors act as back-up for the primary sensors in Mixing Chamber Nos. 3 and 8, current I&C configurations rely on the readings from level sensors in individual mixing chambers to run the high, mid-, and low-level mixers. As such, the ten level sensors can be removed, but only if the signal from the primary ultrasonic level sensors are retrofit with an output relay to replace this function provided by the individual channel level sensors.

Modifications to allow removal of these level sensors are included in the cost estimate. Removal of the 10 redundant level sensors will reduce I&C maintenance on these sensors.

Provide new flow meter for dewatering flow downstream of the junction chamber. Operations has expressed a desire to have flow measurement for the dewatered flow that is pumped from the basin to the sanitary sewer. The recommendation is to install a non-contact laser flowmeter downstream of the junction chamber in an existing manhole. This meter should provide accurate enough data in this 48-in. larger diameter sewer. Figure CON-I&C-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the plan and profile of the sewer and the area of interest where the flow meter should be installed.

Figure 8-8. Conner Creek CSO Facility Level Sensor Identification

Evaluate replacement options for valve control network. See Section 5.4.6 for details of the Valve Control Philosophy – Valve Network (Pakscan) versus hardwired control. The recommendation is to continue the use of the Pakscan valve network for data and status while upgrading the 16 effluent relief gates valve controls to hardwired control.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 8-18. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 includes the in-kind replacement for all level sensors.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 1 include maintenance of the valve control network and the level sensors (downstream of the screens).
- The O&M costs for Alternative 2 include maintenance of the new instruments and cameras. It is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 1, Do Nothing/Replace In-Kind, is the Best Value Alternative. The total benefit score for Alternative 2, however, is 0.6 higher than Alternative 1 due to improved component performance and ease of O&M. The NPV/benefit value of Alternative 2 is approximately \$157,000, which is a moderate cost compared to other projects recommended in this assessment. As such, **Alternative 2 - I&C Improvements, is the recommended alternative.**

Control System Upgrade (Project CON-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 8-19 provides the summary of the Control System Upgrade, which is the recommended alternative. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title.

Table 8-18. Alternative Evaluation for I&C Improvements (Project CON-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.68	\$ 60,900	\$ 10,000	\$ 271,796	\$ 101,291	Best Value Alternative
	<i>Definition:</i>	Replace level sensors in-kind.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 331,000	\$ 9,000	\$ 520,807	\$ 157,027	
	<i>Definition:</i>	Removal of redundant level sensors; addition of new flow meter for dewatering flow; provide tank level indication; upgrade effluent relief gate valves controls to hardwired control; and install process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Table 8-19. Alternative Evaluation for Control System Upgrade (Project CON-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,678,000	\$ 1	\$ 1,678,021	\$ 559,340	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.8 Site

8.2.8.1 Description of Existing Site

There is an access road to the site off Freud Avenue. The access entrance gate to the site is a 30-ft wide sliding vehicular gate across the 40-ft wide access road. Site security is provided by a 6-ft high ornamental fence along the north perimeter of the site. This includes the entrance gate located on the south side of Freud Avenue. The fence starting at the west end of the entrance gate extends easterly along the south right of way of Freud Avenue, extending around the stormwater detention pond and then ending at the creek. A 6-ft chain link fence is located at the west perimeter of the site facing the Federal Aviation Administration Tower Area. Site concrete sidewalks are 3 to 5 ft wide and approximately 4 in. thick. The site parking and drive areas are paved with 4.5 in. of asphalt on 10 in. of aggregate. The gravel drive farther south of the building is 8 in. thick.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

8.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- The entrance gate has reached the end of its useful service life
- Water ponds on top of the basin. In the winter, this water freezes and causes safety concerns
- Sidewalks have settled and heaved, causing safety issues and water infiltration next to building

8.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project CON-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) Alternative 1: Do Nothing.

2) Alternative 2: Site Improvements including,

- Replace Entrance Gate
- Address ponding on basin deck
- Replace Sidewalks in Select Areas

Each of the site related improvements listed above is described further below:

Replace Entrance Gate. The entrance gate at the Conner Creek CSO facility is a 30-ft wide automatic cantilever sliding gate. The gate has been subject to numerous recent mechanical failures. The gate has reached the end of its useful service life and is recommended to be replaced with a new similar style gate.

Address Ponding on Basin Deck. There are areas of significant ponding on the basin roof deck. Several of these areas are located on the east side of the deck adjacent to the Conner Creek canal. To remediate the ponding issue, it is recommended that holes be cored through the basin roof to allow discharge of ponded water to the basin. Recessed area drains would be installed in the cored holes to the basin. For those areas adjacent to the canal, scuppers through the basin parapet wall should be investigated to relieve ponded water directly to the canal.

Replace Sidewalks in Select Areas. The sidewalks next to the Control Building have settled, pulling away from the face of the building and allowing water to infiltrate the joints at the base of the building and sidewalks. This leads to heaving of sections of sidewalk and creates uneven sections, which is a safety concern. It is recommended that all damaged concrete sidewalk flags be demolished. In addition, the expansion joints at the face of the wall should be replaced and the joints caulked and sealed to prevent water infiltration.

The alternative evaluation is presented in Table 8-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Alternative 1 based on the improved health and safety and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$24,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 8-20. Alternative Evaluation for Site Improvements (Project CON-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety concerns uneven sidewalks and from ice buildup on the basin in winter.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 85,000	\$ -	\$ 85,000	\$ 24,286	Not Applicable
	<i>Definition:</i>	Replace entrance gate, sidewalks and core holes through deck at low points.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Restores sidewalks and removes water from top of basin.	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

8.2.9 Architectural

8.2.9.1 Description of Existing Facilities

The Conner Creek CSO Facility consists of a chemical room, chemical storage room, utility support (electrical and mechanical), control room, sample room, office area, hydraulic room, screen room and other miscellaneous rooms. The facility also includes adjoining retention basin.

8.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

8.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (CON-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Clean and coat bottom of all door frames
 - Remove corrosion from localized areas in roof framing, clean and coat
 - Apply skim coat and slope to redirect water to creek outside the Screening Building

- Provide flashing/ membrane system to protect column bases from ponding moisture to address pooling water between building/brick walls and to fix gap between brick and steel columns
- Clean and repaint surfaces where paint is debonding in Screening Building
- Remove and replace deteriorated ceiling tile in Control Building
- Remove and replace floor control joint sealant
- Investigate and repair water intrusion at door in Screening Building
- Address door hardware issues and door and door frame corrosion issues
- Clean rusted areas of structural steel column base of exterior Screenings Building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure CON-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (CON-DIS-1).

The alternative evaluation is presented in Table 8-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 8-21. Alternative Evaluation for Architectural Rehabilitation (Project CON-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 361,000	\$ -	\$ 361,000	\$ 116,452	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.10 Safety

8.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

8.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 8-22. The capital improvement project to address these issues is included in the table.

Table 8-22. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Headworks – between bar screen No. 8 and No. 9 platforms	Railing does not extend over belt – fall hazard	Extend railing	Safety Improvements (Project CON-SAFE-1)
Stair B6 (Compartment 2) (Representative of all stair locations to basin)	No illuminated exit signs	Add or replace exit signs	Exit Sign Improvements ^a
Headworks – the “walkway” under the screenings conveyor and between grit rollofs	“Walkway” does not meet exit access width requirements – not adequate width, overhead hazard, column in center of walkway	Reroute personnel or the column/overhead horizontal beam will need to be moved	Conner Creek Conveyor Improvements ^b
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project CON-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

^b This project will be completed under the JOC.

8.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project CON-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing between bar screen #8 and #9 platforms to eliminate fall hazard
- Address fall protection

Because the importance of these issues relate to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 8-23 shows the one alternative.

Table 8-23. Alternative Evaluation for Safety Improvements (Project CON-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 358,000	\$ -	\$ 358,000	\$ 119,333	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection and fall hazard.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

8.2.11 Supporting Infrastructure

8.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

8.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- Dredging of the Conner Creek, based on analysis in the WWMP.

8.2.11.3 Discussion and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section.

Dredging of Conner Creek Channel (CON-SUPP-1). The WWMP investigated the accumulation of sediment within the Conner Creek channel that could potentially limit the discharge capacity of the Conner Creek CSO Facility. During peak wet weather events, it is necessary that the hydraulic capacity of the channel be sufficient to convey overflow from the facility to the Detroit River. Restrictions in the channel could reduce hydraulic capacity causing backup and potential surcharging within the RTB and collection system.

Section 8.8 of the WWMP presents the results of the physical investigation into the amount of sediment that has built up since the facility start-up in 2005. Based on the results of the survey, sediment deposition within the channel varies in depth from 0 to 3 ft, representing approximately 21,000 cubic yards (+/-20 percent) of sediment to be removed.

A cost estimate for dredging accumulated sediment within the Conner Creek channel was developed based on the assumption that the dredging operation will be performed using hydraulic dredging equipment similar to 2005. A material quantity of 35,000 CY was assumed for the estimate, assuming dredging will occur within the next 10 to 15 years. The total estimated cost of the project is \$11 million. For details are provided in Section 8.6 of the WWMP.

8.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Conner Creek CSO facility, Table 8-24 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table

8-24, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 8-24. Listing of Asset Condition Assessments for Conner Creek Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset. Another one of the building asset listed as "PLANNING - ORDERING PARTS/FILLING OUT WORK ORDER/COMPLETING INVENTORY OF PARTS ON HAND. (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is also not an asset.

^b The fire suppression was evaluated Simplex Grinnell in 2018 and not included in the ACES report.

^c The one gas detector is a portable unit and was not assessed.

^d The 46 individual flushing gates were not assessed. These were assessed as a group. The individual gates are being considered for removal from WAM.

^e The second sampler (ES-2) is listed as inactive and is being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the

Conner Creek Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

8.3 Capital Planning for Conner Creek CSO Facility

8.3.1 Summary of Capital Improvement Plan Projects Alternatives

Table 8-25 provides a summary of the recommended CIP projects and associated capital costs for the Conner Creek CSO facility based on the alternative evaluations conducted for this facility.

Table 8-25. Summary of Recommended Projects at Conner Creek CSO Facility

Project No.	Alternative	Description	Total Project Cost
CON-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 2,300,000
CON-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
CON-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
CON-DIS-4	1	Do Nothing – Continue to Use Heat Tracing and Replace at Regular Intervals	\$ 144,000
CON-FD-1	2	Screening Distribution Channel Improvements	\$ 2,880,000
CON-FD-2	1	Flushing Water System Improvements Using River Water	\$ 2,692,000
CON-HVAC-1	2	HVAC Improvements	\$ 116,000
CON-ELEC-1	2	Electrical Improvements	\$ 129,000
CON-I&C-1	2	I&C Improvements	\$ 331,000
CON-I&C-2	1	Control System Upgrade	\$ 1,678,000
CON-SITE-1	2	Site Improvements	\$ 85,000
CON-ARCH-1	2	Architectural Rehabilitation	\$ 361,000
CON-SAFE-1	1	Safety Improvements	\$ 358,000
CON-SUPP-1	1	Dredging of Conner Creek Channel	\$ 11,000,000

8.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 8-26. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 8-26. Capital Improvement Plan Projects for Conner Creek CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
CON-1 Disinfection System Improvements	\$ 2,456,000	2035 <i>Timing based on asset condition</i>	CON-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 2,300,000
			CON-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
CON-2 Flushing System Improvements	\$ 5,572,000	2028 <i>Timing not dependent on existing asset condition</i>	CON-FD-1	Screening Distribution Channel Improvements	\$ 2,880,000
			CON-FD-2	Flushing Water System Improvements Using River Water	\$ 2,692,000
CON-3 HVAC Improvements	\$ 116,000	2033 <i>Timing based on priority of other needs</i>	CON-HVAC-1	HVAC Improvements	\$ 116,000
CON-4 Facility-Wide Electrical and I&C Improvements	\$ 2,138,000	2029 <i>Timing based on asset condition</i>	CON-ELEC-1	Electrical Improvements	\$ 129,000
			CON-I&C-1	I&C Improvements	\$ 331,000
			CON-I&C-2	Control System Upgrade	\$ 1,678,000
CON-6 Facility-Wide Safety and Architectural Improvements	\$ 719,000	2023 <i>Project should be initiated as soon as possible</i>	CON-ARCH-1	Architectural Rehabilitation	\$ 361,000
			CON-SAFE-1	Safety Improvements	\$ 358,000
CON-7 Dredging of Conner Creek Channel	\$ 11,000,000	2041 <i>Timing of project should be re-evaluated in about 2031</i>	CON-SUPP-1	Dredging of Conner Creek Channel	\$ 11,000,000
CON-10 Model Disinfection Performance	\$ 50,000	2021 <i>Timing based on potential for major maintenance cost reduction</i>	CON-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 8-27 and Table 8-28 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 8-28 indicates that CON-DIS-1 project has two assets that need to be replaced immediately due to condition score of "5". These assets, however, have already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining 109 assets that are included in this project have an average condition score of 1.86 and an average replacement date of 2035. This information was used to propose a scheduled construction completion date of 2035.

Table 8-27. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
CON-DIS-1	109	1.19	1.86	2.28	22	2035	\$ 2,271,000
CON-I&C-2	2	2.29	1.57	4.08	12	2029	\$ 994,990

Table 8-28. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
CON-DIS-1	2	1.29	5.00	4.50	10	2021	\$ 108,000
CON-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -

There are recommended capital improvement projects presented in Table 8-26 that could be better delivered under capital outlay projects. These projects are listed in the following bullets:

- Continue to Use Heat Tracing and Replace at Regular Intervals (CON-DIS-4)
- Site improvements (CON-SITE-1) for the entrance gate replacement, sidewalk repair and basin drainage.

For the CFD Modeling of Mixers (CON-DIS-3), it is ultimately recommended to include this project with similar modeling projects at the Baby Creek and Leib CSO Facilities. See Section 2 (Volume 1 – Project Introduction and Capital Improvement and Outlay Plans) for proposed bundling of this project.

8.3.3 20-Year Capital Outlay Plan

Table 8-29 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 8-29. 20-Year Capital Outlay Plan for Conner Creek CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 751,200	\$ -	\$ -	\$ -	\$ 743,000	\$ -	\$ -	\$ 8,200	\$ -	\$ -	\$ -	\$ -	\$ -
2022	\$ 7,488,582	\$ -	\$ 16,962	\$ 2,867,520	\$ -	\$ -	\$ 4,604,100	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -

2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 41,609,855	\$ 408,190	\$ 477,699	\$ 18,578,322	\$ 10,117,804	\$ 1,627,505	\$ 4,604,100	\$ 2,737,954	\$ 126,107	\$ 1,260,424	\$ 252,402	\$ 189,992	\$ 1,229,358

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Flushing gate systems for basin distribution channel, screening distribution channel, and Compartment 1 to 4 received scores of 5 at the time of the Condition Assessment because some of the flushing gates were not functioning. A project to rehabilitate the gates is planned for late 2021.
- Disinfection System: One of the four mixers was covered in debris and the remaining three mixers were out of service at the time of the Condition Assessment (\$50,000 each; \$200,000 total) and received a score of 5. Two chemical feed pumps (\$54,000 each; \$108,000 total) were being repaired at the time of the Condition Assessment. The two Accusonic flow meters (\$217,500 each; \$435,000 total) were not installed at the time of the Condition Assessment.
- Odor Control System: Three scrubber systems (\$1,534,700 each) received scores of 5 since the motor (child of fan) was not functional at the time of the Condition Assessment.

9. Hubbell-Southfield CSO Control Facility

9.1 General Facility Description and Future Capacity Considerations

9.1.1 General Facility Description

The Hubbell Southfield CSO Facility is an RTB with 22 MG of storage, and a treatment capacity of 3,200 cfs. It was constructed in 1996. There are two buildings on site - a Headworks Building and a Control Building. The headworks building contains a headworks area, chemical room, mechanical room, and an odor control area. The control room building contains the control room, odor control room, work area, electrical room, basement area, restroom, locker room, and mechanical room.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

9.1.2 Future Capacity Considerations

There were no future capacity considerations identified at the time of this report.

9.2 Facility Assessment

9.2.1 Screening

9.2.1.1 Description of Existing System

The Hubbell-Southfield CSO Facility has six catenary bar screens that were installed in 1996. Screenings from the screens are discharged to a single conveyor belt, which conveys the screenings to a dumpster. The screenings are disposed in a landfill.

Table 9-1 provides an overview of the existing screening system at Hubbell-Southfield CSO facility.

Table 9-1. Overview of Existing Screening System Hubbell-Southfield CSO Facility

Parameter	Value
Treatment Capacity (cfs)	3,200
No. of Screens	6
Manufacturer	Jones and Atwood
Screen Type	Catenary Bar Screen
Opening Size	1.5-in. slot
Depth or Length / Width	22 ft 0 in / 9 ft 6 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

9.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide a screening retention plate along entire conveyor to prevent screenings from falling off the conveyors at the back of the screens.

- O&M staff noted that the grating over the bar screen channel deflects when walking on it
- Prevent the edges of the bar screen rakes from dragging on concrete. This issue has been added to the scope of the OEM evaluation. This issue has been added to the scope of E&I's assessment, which has not occurred as of the time of this report. If there are capital costs associated with the retrofit to address this issue, it will be added based on OEM input.
- Prevent screens from swaying during operation. During higher flow events, the screens reportedly sway to some degree. The operators believe this is caused by the returning rake getting tossed by the rapid flow of water and affecting the rest of the screen. They noted that the Conner Creek screens (which is a similar screen but does not sway) has chain guide returns that extend closer to the floor of the channel. This issue was added to the scope of the OEM evaluation; however, the OEM was unable to see the swaying because flow did not occur during the site visit. If this issue causes problems in the future, it should be video-taped to document the issue.
- O&M staff noted that the overhead crane pendant is old and bulky.

9.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Screening Improvements (Project HS-SCR-1). Due to the relatively small nature of some of the screening-related projects identified as improvements, all of the identified screening improvements are proposed to be in one project – Screening Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Screening Improvements** including,
 - Screening Retention Plate Along Entire Conveyor
 - Walkway Grating Over Bar Screen Channels
 - Replace Overhead Crane Pendant

Each of the screening related improvements listed above are described further below:

Screening Retention Plate Along Entire Conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt. A cost for a screening retention plate (similar to screening retention plate at Conner Creek) is included in the capital cost estimate.

Walkway Grating Over Bar Screen Channels. O&M staff reported that grating does not feel sufficient (i.e., it deflects when walking on it). A cost for grating replacement is included in the capital costs.

Replace Overhead Crane Pendant. O&M staff indicated the current push-button, explosion-proof crane pendant is old and very bulky (Figure 9-1). Jacobs contacted Crane Technologies to obtain a replacement cost for a new pendant.

Figure 9-1. Existing Pendant for Overhead Crane at Hubbell-Southfield CSO Facility

The alternative evaluation is presented in Table 9-2. Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.

The total benefit score for Alternative 2, however, is about 1.0 higher than Alternative 1 due to improved health and safety, component performance, and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$54,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the advantages with this alternative, Alternative 2 – Screening Improvements is the recommended alternative.**

Table 9-2. Alternative Evaluation for Screen Improvements (Project HS-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.62	\$ -	\$ -	\$ -	\$ -	Not Applicable

9.2.2 Disinfection

9.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP storage tanks, five gear pumps, and three induction mixers. There are six screens discharging into a common influent channel from which flow is directed to Basin Compartment 1 or to the Shunt Channel which can feed Basin Compartment 2. There are three induction mixers located upstream of the bar screens. The sodium hypochlorite pumps discharge to a common header with a flow meter that splits to the three induction mixers, the Shunt Channel, Basin 1, Basin 2, flushing, and odor control. During an event sodium hypochlorite is normally only fed to the three induction mixers. Flow splitting is not metered and there does not appear to be any basis for throttling the valves to individual induction mixers to achieve equal flow splitting. Table 9-3 provides an overview of the existing disinfection system at Hubbell-Southfield CSO facility.

Table 9-3. Overview of Existing Disinfection System at Hubbell-Southfield CSO Facility

9.2.2.2 Identified Needs and Issues

The needs and issues identified for Hubbell-Southfield were identified from meetings with O&M staff and Jacobs team site visit and investigations. The identified needs and issues are listed in the following bullets:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Hubbell Southfield chemical feed system has the following issue:
 - The feed pumps are in a confined basement are on short pump pads and as such at risk of being damaged if there was a spill or water leak.
 - The sump pumps in the feed pump area were not designed for corrosive or chemical service and have been damaged by exposure to sodium hypochlorite. Replacement with sump pumps suitable for corrosive chemical service is desired.

These issues are addressed in Replace Chemical Feed System (Project HS-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant,

overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project HS-DIS-2) below.

- Hypochlorite storage capacity is reportedly not enough for large storm events. GLWA requested that Jacobs investigate this issue. Jacobs found that the concrete containment area used for existing spill containment was the original sodium hypochlorite storage. The two existing 15,000 gallons FRP tanks installed in the original concrete storage tanks provide less chemical storage than the concrete tanks. Historical chemical usage from the four largest wet weather events from 2016 through 2018 was evaluated for all of the CSO facilities, including Hubbell Southfield. The data indicate that the volume of sodium hypochlorite fed exceeded the storage volume at Hubbell Southfield in one event. In that event 38,775 gallons was reportedly fed compared to 30,000 gallons storage volume. Chemical deliveries occurred during the event to address this. Based on the event above, additional hypochlorite storage is needed. This issue is addressed in Add New Chemical Storage Tank (Project HS-DIS-3).

9.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project HS-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel. Hose pumps will be larger than the existing gear pumps at Hubbell-Southfield and the need to enlarge the pump area was considered for this alternative. Although not all pumps may fit in the current row of pumps, there appears to be sufficient room to locate a couple of the pumps along the north wall under the stairway if necessary. The costs for demolishing the existing pads and adding new taller and larger pads was included in all alternatives and the cost will not substantially change with pump location. Details regarding pump layout are deferred to design.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to the Hubbell Southfield feed system:

- **Sump Pump:** For cost estimating purposes, a chemically resistant sump pump is assumed for the sump in the chemical feed basement areas as well as hard-piped dilution water to the sump requested by plant personnel.
- **Spill Protection:** Jacobs evaluated two options to address the concern of sodium hypochlorite spill in the pump area, including:
 - **Option 1: Level sensors and raising pump pads.** This option would install a level sensor or contact switch in the pump area. The sensor would be programmed to close actuated valves from the tanks if a spill is detected. Also, this alternative includes raising the pump pads to 2 ft (from their current 4 in.) to further protect the pumps if a spill occurred.
 - **Option 2: Transfer Pump and Day Tank.** This option would include the sensor in Option 1 that would close the tank valves if a spill should occur. This option would also provide a transfer pump and day tank. However, the transfer pumps would remain a weak link in a flood. In order to address this, a vertical shaft

chemically resistant sump pump with the motor located above maximum flood level, as offered by Vanton Pumps, would serve as an emergency backup to a transfer pump. In a flood situation, the sump pump would serve as the transfer pump to the day tank or to return the sodium hypochlorite to one of the storage tanks after that tank's outlet valve is closed.

The cost for a level sensor in the pump area and programming to close actuated valves from the tanks if a spill is detected is a relatively low-cost alternative. As such it is included in Alternatives 2 and 3 above.

The alternative evaluation for these alternatives is presented in Table 9-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 was developed based on GLWA experience of pump rebuilds per year at a cost of \$30,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 9-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 9-4. Alternative Evaluation for Replace Chemical Feed System (Project HS-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project HS-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time must also be considered. The exact location would be determined during design.

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 9-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. Based on the improved ability to meet the NPDES permit TRC goal, **Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 9-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project HS-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Add New Chemical Storage Tank (Project HS-DIS-3). Based on the evaluation performed in the previous section, there is a need for additional chemical storage tank to ensure adequate chemical during larger events. There are two alternatives:

- 1) **Alternative 1: Do Nothing - Rely on Chemical Deliveries during Storm Event.** This approach was used during the large event that exceeded the existing chemical storage capacity. This alternative relies upon an outside contractor to deliver enough hypochlorite to make it through the storm event.
- 2) **Alternative 2: Add New Chemical Storage Tank.** The O&M staff requested a tank at grade to serve as a backup. They also requested the capability for gravity feed to the influent from the new tank in case the pump room floods. The lack of reliable influent flow measurement prevents sizing additional sodium hypochlorite storage based on influent flow, design doses, and assumed hypochlorite strength considering degradation potential. However, the installation of new flow meters in 2019 may help to inform tank sizing for design. For budgeting purposes, a third tank sized the same as the existing two 15,000 gallon tanks is assumed, inside a building with chemical containment, mechanical, electrical and I&C.

As requested by GLWA, the possibility of gravity feed from the chemical tanks with a meter and valve was evaluated. The effluent weir from the CSO basins into the effluent channel controls the hydraulic grade line at the influent induction mixers to above elevation 100 once the basin is filled. The bottom of a new at-grade sodium hypochlorite tank would be approximately elevation 111 and the maximum liquid depth is approximately 13 ft. Thus, there is approximately 11 ft of static head available with the tank empty and 24 ft with the tanks full. This corresponds to 4.8 pounds psig empty to 10.3 psig full available head. The induction mixers require back pressure valves to prevent siphoning chemical. Evoqua recommends a setting of 15 psig. Therefore, the available static head is inadequate for gravity feed before even accounting for friction loss and flow control valve loss. Thus, continued pumping as the means of chemical delivery is recommended.

The alternative evaluation is presented in Table 9-6. Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.

As shown in Table 9-6, Alternative 2 has a Total Benefit score about 1.5 higher than Alternative 1 because of the improved water quality and compliance (i.e., facility could run out of chemical during a storm and violate permit), and ease of O&M. Because of the risk of violating permit, **Alternative 2 is the recommended alternative.**

Table 9-6. Alternative Evaluation for Add New Chemical Storage Tank (Project HS-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/Rely on Chemical Deliveries during Storm Event	Health and Safety	3	2.00	\$ -	\$ -	\$ -	\$ -	Not Applicable

	<i>Adv.:</i>	Lower Cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	May run out of chemical during a large storm event, thereby violating permit.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Add a New Chemical Storage Tank	Health and Safety	3	3.50	\$ 753,000	\$ -	\$ 753,000	\$ 215,143	Not Applicable
	<i>Definition:</i>	Install new tank at grade to serve as a backup with capability for gravity feed	Water Quality & Compliance	4						
	<i>Adv.:</i>	Sufficient chemical for larger storm events.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.3 Odor Control

9.2.3.1 Description of Existing System

The Hubbell Southfield odor control system consists of two separate horizontal cross flow scrubber systems. Odorous air flows horizontally across the empty scrubber chamber and scrubbing solution is sprayed into the oncoming air from numerous spray nozzles. One system, located in the Headworks Building, treats air from the Headworks area and Basin No. 1. A second system, located in the Process Building, treats air from Basin No. 2. The systems were originally designed with the capability to spray a solution of sodium hypochlorite and sodium hydroxide to remove odorous gasses. However, the sodium hydroxide has not been used for some time. The chemical solution is recycled through the scrubber and recirculation tank, and fresh sodium hypochlorite is added as needed. Excess chemical solution overflows out of the recirculation tank into a drain.

The system was installed in 1996. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no formal odor complaints have been received for at least the past three years; however, the golf course has indicated that they can smell the facility.

9.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack. (This could be considered during the winter months when the golf course is not active, but is not recommended when the golf course is being used.)

Odor Study. Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous or non-detectable to receptors. Prior to implementing either one of these options, GLWA should conduct an odor study to sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water. The study would also sample the discharge when using water spray, to determine the measured effectiveness of such an operation.

9.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs."

9.2.4 Flushing and Dewatering

9.2.4.1 Description of Existing System

Dewatering System: Basin dewatering can be accomplished by gravity or pumping. Gravity dewatering to the Northwest Interceptor (NWI) occurs by opening one of two flow control valves (BD-1 or BD-3). A control system regulates the valve position and corresponding flow from the basin to the NWI. The gravity discharge rate is controlled so as not to exceed the remaining capacity in the NWI as measured by a level sensor in the NWI. The Basin Compartments 1 and 2 can be dewatered from a basin water level of 99.5 ft down to about 94.75 ft. The basin could be dewatered by gravity down to 90.5 ft (if siphoning); however, at a water surface level below 94.75, the flow rate in the discharge line causes the velocity to drop below a recommended value of 3.5 ft/sec.

The remainder of volume in the basin must be removed by pumping. There are two 8,000 gpm pumps for each basin, for a total of four dewatering pumps. The system was designed for one pump as duty, with the other pump as backup. The dewatering pumps were designed to remove water down to about 74.5 ft, which is about 25 ft below the basin high water level.

The dewatering system originally included one 200 gpm sump pump for each compartment. These pumps have been removed. As noted below, Operators would like to see this pump replaced.

The basin was also designed to be decanted if there was no capacity in the NWI before a subsequent storm. The top 5 ft of water from the basin compartments could be decanted to the Rouge River. There are two decant gates located at the end of Basin 2: Basin Decant Slide Gate and Effluent Decant Gate. The Operators have not decanted flow and do not foresee the need to decant in the future. As such, these gates should remain closed and do not need to be replaced in the future. These gates could be removed in the future and the openings permanently filled with concrete.

Flushing System: The spray flushing system is intended to remove the remaining solids left on the floor of the basin and shunt channel after the basin has been dewatered. There are 22 flushing spray zones. Two submersible flushing water pumps are located in the effluent channel (referred to as the Pond) and a strainer is located in the Process Building dewatering pump room. If there is not enough effluent after a wet weather event in the effluent channel for the basin flushing, additional (City) water can be used to fill the effluent channel. The Pond fills at line pressure and there is no booster pump to help it fill faster.

The flushing system has not performed its intended function since it was originally installed. Solids accumulate across both basins and in the shunt channel. As such, the operators must lower a bobcat into the basin and use fire hoses to clean solids from the bottom of the basin. Due to the extraordinary difficulty of cleaning the basin, GLWA does not clean the basin after every event.

Table 9-7 provides an overview of the existing flushing and dewatering system at Hubbell-Southfield CSO facility.

Table 9-7. Overview of Existing Flushing and Dewatering System at Hubbell-Southfield CSO Facility

Parameter	Value
Total Basin Volume (MG)	22
Headworks and basin Dewatering and Flushing System	- Gravity dewatering can occur for the top portion of captured volume, but this is not typical operation - There are two 8,000 gpm dewatering pumps for Basin 1 and two 8,000 gpm dewatering pumps for Basin 2 - Two 5,000 gpm flushing pumps are located in the effluent channel. A strainer is provided in the Process Building Basement. - Flushing system consists of spray flushing system with 22 zones. System is largely ineffective at removing solids from the basins

9.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- There are significant issues with flushing solids from the floor of the basin and shunt channel.
- The dewatering pumps need to be upgraded and missing sump pumps need to be replaced. A fluidization system should be considered under the sump pumps to avoid large accumulations of solids in the sump
- There is no way to access to the effluent channel (Pond) area.

9.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Basin Flushing System (Project HS-FD-1). Flushing solids from the floor of the basin and shunt channel has been a problem since the facility was constructed. The existing flushing system using spray nozzles has been largely ineffective due to the large volume of solids that are generated during each storm and the fact that a subsequent storm may enter the facility before the entire contents have been cleaned. The configuration of the spray system (15 ft above the floor) also makes the spray system ineffective.

There are three alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Continue Current Operation.** GLWA Operations staff to continue to manually clean the basin.
- 2) **Alternative 2: Contractor Clean Out.** Contractor to manually clean the basin. This alternative is similar to Alternative 1; however, it would include increased number of cleanings per year to meet the intent of the permit to have the basin ready for a subsequent storm event.
- 3) **Alternative 3: New Basin Flushing System.** Based on the poor performance of the existing spray flushing system at Hubbell Southfield and experience at another CSO basin in the Southeast Michigan region (Milk River CSO Basin), GLWA requested a completely new system. Jacobs initially considered both flushing gates and tipping buckets to replace the existing system. After consultations with several manufacturers and evaluating initial conceptual layouts, tipping buckets were removed from consideration due to the low head space inside of the basin areas and maximum flushing length limitation of only 200 ft. As such, the recommended flushing system involves flushing gates/reservoirs in the contact basins and an improved spray system in the shunt channel. This concept is shown in Figure HS-FD-1-ALT-3 in Volume 6 – Appendices, Appendix B.

Demolition. The demolition activities consist primarily of removing of the existing basin mixers and spray system components (pumps, pipes, fittings), concrete removal for construction and permanent access through the roof slab, and other equipment mounted inside of the tank to allow the extensive structural concrete placement. Temporary relocation of some equipment and piping/conduits on top of the tank to facilitate construction is assumed.

Flushing Gate Reservoir Configuration. The existing basin's semi-circular configuration, slope, alignment of the NWI dividing basin into two sections, and drainage channels create a challenging retrofit condition. Flushing gate reservoirs will be located along three lines in the upstream and downstream sections of the two basin compartments. The reservoir volume is determined by the length and slope of the surface that must be flushed by the flushing wave. The longest flushing length is along the northeastern wall of the facility is approximately 430 ft long. The average flushing reservoir volume for the conceptual configuration is approximately 15,000 gallons. The final design should validate and further refine the minimum volume requirement using a sediment fate-transport model (e.g., HEC-RAS) for each flushing lane based on length

and longitudinal channel slope. For 37 flushing reservoirs, the total flushing volume required is approximately 550,000 gallons.

Immediately downstream from the screens, an initial reservoir array will be constructed in Basin 1 with the flushing gate reservoirs suspended above the basin floor and with the gate openings directed towards the existing drainage channel in the upstream section. The suspended reservoirs, as shown in Figure HS-FD-1-ALT-3, allow low flows to continue underneath into the basin in a 2- to 3-foot high channel. As the water level continues to rise in the basin, the hydraulic gradient will build upstream of the suspended reservoirs and increase the velocity in the low-flow channel, effectively moving sediment into the basin sump and the dewatering pump station. Flows will eventually overtop the flushing gate reservoir walls (approximately 8 ft above the floor) and fill the reservoir volume.

A second array of flushing reservoirs is proposed in Basin 2 on the downstream side of the NWI alignment. The reservoirs of this array would be constructed on the existing basin floor with the gate openings directed towards the drainage channel that runs through the middle of Basin 2. The third and final array would be constructed along the finger weirs near the basin outlet. These reservoirs would also be constructed on the floor with the gate openings directed back towards the drainage channel in the middle of Basin 2.

Structural Retrofits. Flushing gates release a flushing wave that needs to be contained in a confined channel to maintain velocity and effectively carry resuspended sediment to a collection point. The basin floors will require concrete training walls along each flushing channel. Additionally, the existing floor will require concrete leveling across most of the entire basin to create level cross-sectional flushing channels. The conceptual design developed indicates that approximately 8,000 cy of concrete fill will be required to create adequate flushing wave channels and reservoirs. Additional concrete fill (structural and low-density concrete fill, approximately 1,000 cy) will be required throughout the basin as fillets and bulk fill to eliminate voids and areas where the flushing waves cannot remove sediment. The total displacement of the new concrete in the contact basin is approximately 1.82 million gallons.

A review of the existing facilities structural details indicate that the base slab could be susceptible to damage if any drainage channel realignments are made. The conceptual design avoids additional base slab structural improvements and subsurface improvements. Additionally, the facility's proximity to surface water and high groundwater would require extensive dewatering should any penetrations through the base slab be required. Additional modifications to the existing base slab, addition of concrete, and other improvements may negatively impact the structure and the foundation. A detailed analysis of the future condition live/dead loads should be completed during final design and structural/foundation improvements incorporated into the project by the final designer. These improvement could include additional piles, retrofitted structural supports, and use of higher strength concrete mixes.

Secondary Flushing Water Source. A secondary source of flushing water is recommended to provide additional flushing cycles for post-event cleaning. The base option for the concept development is to repurpose the existing flushing system water source and install a pipe network to fill the reservoirs in each array. A second option is to use a surface water source, similar to St. Aubin CSO Facility. The close proximity of the Rouge River at the outfall end of the facility allows for the installation of a pump intake, pump system and force main to provide water for a fill pipe network in the contact basin above the reservoirs. GLWA should consider large screens (4-in. bar-type or similar) to prevent floating debris from entering the effluent chamber. GLWA's experience with zebra mussel removal from other facilities in this area indicates that smaller screen openings should be avoided. Similarly, a small opening with a flap-gate opening inward to the effluent channel may help prevent floating debris from entering while ensuring adequate water is available for secondary flushing and shunt channel spray system operation.

The recommended alternative assumes each array of flushing gate reservoirs will be filled using surface water as the flushing water source, similar to the St. Aubin flushing system. Two 2,000-gpm submersible pumps will be mounted in the existing effluent channel. Each pump will discharge to separate 6-in. HDPE force mains that are mounted to the interior roof of the contact basin space (either at the centerline of the overall basin, or

along one wall). One pump will provide flushing water to the northernmost flushing reservoir array, and the other will provide flushing water to the other two arrays. At each array, a second run of 6-in. HDPE will extend over the top of the flushing reservoirs with a tee fitting. A concrete notch (3 ft long by 6 in. deep) cut into the walls between each reservoir would serve as a weir and will enable flows between the reservoirs to fill evenly as the pumps operate.

GLWA has noted that Basin 2 tends to accumulate more solids from wet weather events than Basin 1 and is expected to require more than one post-event flushing with the proposed flushing gate system. By dedicating one pump to the Basin 2 flushing gate arrays (closest to the finger weir), GLWA will be able to more quickly fill these reservoirs to provide a secondary cleaning of this area (estimated fill time at 2,000 gpm of 100 minutes). The other flushing reservoirs in the northern half of the basin will fill more slowly (approximately 180 minutes).

Alternative Gravity Filling System for Basin 2. A sub-alternative for filling the flushing gate reservoirs includes adding a new gated opening or repurposing an existing gated opening in the finger weirs between Basin 2 flushing chamber and the Pond. Each flushing reservoir will have a lower weir notched into the concrete walls between adjacent flushing reservoirs. Opening the gate will allow river water from the reservoir to quickly fill this array of flushing gate reservoirs from one source via overtopping the notched weirs and provide water for additional flushes. A screened and gated opening between the reservoir and the river channel is required to control flows into this space and limit floatable materials and larger aquatic organism from entering the facility. Pumping river water to the other flushing reservoirs using pumps would still be required with the conceptual configuration proposed. Extending a gravity pipe to the other arrays may be possible by adjusting or reconfiguring the elevations and layout of the proposed concept.

New Shunt Channel Flushing System. A new spray flushing system is proposed for the shunt channel. Two new flushing headers will be extended into the shunt channel on both sides of the conduit, and two new submersible pumps will draw river water from the effluent chamber near the secondary flushing gate water source pumps described above.

Each pump will provide water to one half of the shunt channel. Record drawings indicate a transverse slope in the channel's shelf of approximately 0.7 to 1.0 percent, draining from the exterior wall towards the low-flow channel next to the interior wall. The low-flow channel has a slope of approximately 0.5 percent and drains the northern and southern effluent channel sections towards the dewatering pumps. The northern (Basin 1) half of the channel will include two 590-foot, 8-in. HDPE (SDR 13.5) headers, mounted with stainless steel hardware approximately 6 ft from the floor, one above the top edge of the shelf and the other over the low-flow channel. Half-in. holes will be directionally drilled on 4-foot spacings to push solids towards the low flow channel, and along the low-flow channel towards the dewatering pumps. The pumping requirement for the northern half system is approximately 3,300 gpm. The southern (Basin 2) half of the channel includes two 280-foot, 8-in. HDPE headers mounted in a similar fashion and drilled accordingly. The pumping requirement for the southern half system is approximately 1,600 gpm. Similarly-sized pipe runs (approximately 560 ft) connect pumps to both headers.

The control strategy may require only running one half of the effluent channel cleaning system at a time in order to prevent overwhelming the dewatering pumps. Control valves to support pulsing may be required and are recommended to be installed on top of the facility or in new vaults installed in the roof. Flow rate, volume/pressure at application points and control strategy should be confirmed during final design using CFD or scale models.

Additional Mechanical Systems. The flushing gate hydraulic systems will require a new control room as the existing surface facilities at Hubbell Southfield do not have adequate space. Therefore, a new control room/building (occupied, declassified space) is assumed and will be constructed on top of the roof slab. The cost estimate assumes a stand-alone building rather than remodeling or adding to either of the existing buildings. An allowance for structural retrofits of the existing tank's roof slab and beams to support a new

surface structure is included in the costs. Hydraulic tubing would be routed inside of the basin along the ceiling to each gate actuator.

Advantages and Disadvantages of Alternative: This flushing gate option described above appears to be the most viable solution for improving the flushing of the basin using automated systems. The advantages of a flushing gate system at this facility include:

- Effective removal of sediment from the bottom of the basin: Currently, the sediment is only removed periodically due to the significant amount of time and effort. The new system should be able to flush the basins every time the basin is dewatered after a storm event.
- Improved NPDES permit compliance by being able to clean the basin after every event. Note that permit prohibits the discharge of sludge or residual accumulations from the basin to surface waters and requires the settled sludges to be promptly removed and disposed in accordance with procedures approved by EGLE.
- Improved safety for GLWA Operations staff: The flushing system eliminates the need for Operations personnel from entering and operating machinery in the confined space.
- Reduced O&M labor costs for sediment removal compared to current process: Currently, it takes about three personnel about one week to clean the entire basin and occurs about four times per year. This represents a cost of about \$50,000 per year.
- Potential reduction in flushing water usage: The existing spray system uses up to about 7 MG of City water after each event. The proposed flushing water system could eliminate the use of City water if river water can be used as the source of flushing water.
- Some other CSO basins in the area (i.e., Milk River) have removed flushing nozzle systems because they are ineffective.

The disadvantages of this system include:

- High capital cost. The cost estimate for the required modifications to the facility to construct a new flushing gate system is significant.
- Additional systems that require O&M: Adding about 37 flushing gates, hydraulic control system, and secondary flushing water system would add the number of assets that require preventative maintenance and replacement. Secondary flushing system pump operation power requirements would increase the facility's overall electrical consumption.
- New concrete used to construct the flushing system will displace approximately 1.8 million gallons of volume in the contact basin. This will reduce the contact time and may impact the CSO facility's ability to meet regulatory permit requirements. GLWA should assess this impact in more detail during final design of this improvement.
- Difficulty of Construction: Factors that make the construction of the flushing gates difficult include construction of the concrete flushing gates and training walls inside a covered basin, relatively tight site conditions, and the need to keep treating CSO flows. (It is noted that Basin 1 could be completely isolated during construction and allow treatment through Basin 2; however, it is not possible under current configuration to isolate Basin 2 and allow flow to be routed only through Basin 1)

The alternative evaluation for these alternatives is presented in Table 9-8. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 1 and 2 is based on the replacement cost of the piping and spray nozzle system in about 2014, inflated to 2021 dollars.

- The O&M costs for Alternative 1 includes GLWA labor cost for four cleanouts per year and associated water usage. The labor cost is based on GLWA labor cost of three staff for 40 hours per week and four times per year, or about \$48,000 per year. The water usage is estimated to be 7 MG per clean-out. At \$4,000 per MG, the cost is about \$112,000 per year.
- The O&M costs for Alternative 2 includes assumed Contractor labor cost for 12 cleanouts per year (average of one per month) and associated water usage. The labor cost is assumed to be about \$20,000 per clean-out, or about \$240,000 per year. This cost is an estimated cost to provide reliable cleaning of the basin on a periodic basis. The water usage is estimated to be 7 MG per clean-out. At \$4,000 per MG, the cost is about \$336,000 per year.
- The capital cost for the flushing system (Alternative 3) is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 3 includes \$10,000 for annual maintenance of the new equipment and electricity costs for the river water pumping.

This evaluation shows that Alternative 1 – Continue Current Operation has the lowest NPV/Benefit cost and is shown to be the Best Value Alternative. The poor health and safety conditions for GLWA operations personnel, however, are not properly conveyed in this analysis and the current four cleanings per year is not believed to be adequate to meet EGLE requirements to have the basin ready for subsequent storm events. Using contracted labor would allow GLWA to have the basin cleaned after most storm events; however, the NPV/Benefit cost is higher than Alternative 3. Alternative 3 provides the benefit of improved health and safety by not having to enter the basin for cleaning, and it is easily operated by the O&M staff after every storm. The Total Benefit score for Alternative 3 is about 2.0 points higher than Alternative 2. **As such, Alternative 3 – New Basin Flushing System is the recommended alternative.**

Table 9-8. Alternative Evaluation for Basin Flushing System (Project HS-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	5						

Dewatering and Sump Pump Improvements (Project HS-FD-2). Sump pumps for Basin 1 and 2 were originally installed next to the basin dewatering pumps. Due to the large accumulations of solids in the sump, these pumps were routinely overwhelmed with solids. As such, O&M staff have removed them from both basins, but they indicated these pumps are beneficial for proper flushing and removal of solids.

There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing/ Replace In-Kind.** Replace the dewatering and sump pumps in-kind.
- 2) **Alternative 2: Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System.** Two new 200 gpm, sump pumps should be installed. It is recommended that a solids fluidization system be installed under the intake of the new sump pumps and the dewatering pumps. This fluidization system could consist of a water jet to fluidize the accumulated grit before the pump turns on. The project should also provide a new base elbow, cleaning of the discharge pipes, replacement of valves on the discharge line, and replacement of the pump rail system.

O&M staff also requested that the type of dewatering pump be investigated to ones that better handle heavy grit loads. The existing four pumps are manufactured by Vaughan. The N-Series submersible pump by Flygt has replaced a number of dewatering pumps at other CSO facilities and are recommended at this location. Based on input from Kennedy Industries, a Flygt Model NP-3202 would be an appropriate replacement pump. The preliminary sizing indicated that these pumps have a slightly lower horsepower than the existing pumps. Detailed design is needed to confirm pump sizing. The elevation of each dewatering pumps should also be investigated (consider one higher than the other to avoid the heavy grit loads).

This project should be incorporated into the flushing gate project (Project HS-FD-1), if the new basin flushing system moves forward.

The alternative evaluation for these alternatives is presented in Table 9-9. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 is based on the pump replacement costs from the SRP.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title. It includes a new fluidizing system to allow the sump pumps to function properly. It also includes new piping to replace the existing and allow the pump elevations to be modified.

Alternative 1 is shown as the Best Value Alternative. The scope of Alternative 2 is generally similar to Alternative 1; however, there are additional improvements in Alternative 2 that are necessary to allow the system to function properly. As such, **Alternative 2 - Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System is the recommended alternative.**

Table 9-9. Alternative Evaluation for Dewatering and Sump Pump Improvements (Project HS-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.58	\$ 429,000	\$ -	\$ 429,000	\$ 166,065	Best Value Alternative
	<i>Definition:</i>	Replace the dewatering pumps and sump pumps in-kind.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Difficulty with flushing and removal of solids.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System	Health and Safety	3	3.42	\$ 950,000	\$ -	\$ 950,000	\$ 278,049	
	<i>Definition:</i>	New dewatering and sump pumps and appurtenances will be installed. A solids fluidization system will be installed under the intake of the new sump pumps.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Proper flushing and removal of solids	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Effluent Channel (Project HS-FD-3). There is no manned access to the effluent channel area (i.e., the area between the effluent weirs and the effluent flap-gates). GLWA needs to access this area to allow equipment to be lowered into this space for removal of settled solids from the floor.

There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing**
- 2) **Alternative 2: Equipment Access to Effluent Channel.** A hatched opening is desired for this area in a location shown in Figure HS-FD-3-ALT-2 in Volume 6 – Appendices, Appendix B. One option is to cut an opening in one pre-stressed concrete plank and use removable covers, similar to the existing hatch shown in the photos in the Appendix. Another option that should be considered during design is providing an aluminum hatch opening, so that a boom truck is not needed to remove the cover.

This project should be incorporated into the flushing gate project (Project HS-FD-1), if the new basin flushing system moves forward.

The alternative evaluation for these alternatives is presented in Table 9-10. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to need to access this location for solids clean-out, **Alternative 2 - Equipment Access to Effluent Channel is recommended.**

Table 9-10. Alternative Evaluation for Access to Effluent Channel (Project HS-FD-3)

9.2.5 HVAC

9.2.5.1 Description of Existing System

The Hubbell-Southfield CSO Facility consists of a Headworks Building and a Process Building. The buildings contain a Headworks area, chemical room, utility support (electrical and mechanical rooms), control room, odor control rooms and other miscellaneous rooms. The facility also includes a retention basin. Table 9-11 provides a summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, emergency shower/eye wash and washroom regular shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 9.2.10.

Table 9-11. Major HVAC Equipment at Hubbell-Southfield CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-3	Heating Ventilating Unit	25,000 CFM
Basin 1	SF-1 to 6	6 × Supply Fans	50,000 CFM
Basin 2	SF-7 to 13	7 × Supply Fans	50,000 CFM
Chemical Room (Headworks Bldg)	EF-2	Exhaust Fan (Hypochlorite Rm)	2,200 CFM
	HVU-2	Heating Ventilating Unit	10,500 CFM
Process Control Bldg	PACU-1	Packaged Air Conditioning Unit	3,400 CFM

Note:

HVU = Heating Ventilation Unit

Table 9-12 provides a summary of the basis of design performance criteria for HVAC systems at Hubbell-Southfield and Table 9-13 provides the outdoor Basis of Design conditions.

Table 9-12. Hubbell-Southfield Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Odor Control Room – Process Building	Unclassified (Per As-Built Drawings)	70	N/A	12 ACH
Work Area, Electric Room, Toilet, Storage, etc., – Process Building	Unclassified	70 (Occupied) 60 (Unoccupied)	78	6 ACH

3	91	73

9.2.5.2 Identified Needs and Issues

During discussions with GLWA O&M staff and GLWA's HVAC contractor, the following HVAC issues were noted:

- Heating in the dewatering room (basement of Process Building) was reported to be insufficient. No freezing of pipes was reported.

Jacobs further investigated this issue through review of design information and site visit. All spaces in the Process Building have a basis of design winter dry bulb temperature of 70°F. The dewatering room's HVU duct heater has a design capacity of 125,000 Btu/h which should be sufficient to heat the dewatering room to 70°F using 80 percent return air, as designed. EF-7 was not observed to be operating. Given the significant amount of corrosion that was observed on EF-7's motorized damper, it is very likely that the damper is seized. This could not be verified in the field due to the inaccessible location of the damper. The observed cold air temperatures in the dewatering room are most likely the result of HVU-4's outside air supply damper remaining fully open during heating mode and/or the return air damper remaining in its minimum position. Given the age of the equipment serving the dewatering room, a replacement in-kind of HVU-4, EF-7 and associated supply, return, and exhaust dampers is recommended and should resolve this issue. This project will come from the SRP.
- O&M staff requested that air conditioning in the Process Building odor control room. Upon further discussion, the main activity routinely performed in this area is sample preparation and analysis. Instead of air conditioning the entire odor control room, it was recommended to move the sample sink to the work area, which is already air conditioned. This is currently an on-going project to be completed by GLWA maintenance staff
- Heating and cooling issues in Process Building. Staff reported that improvements were needed.
- Historical Issues with Heating and Ventilation Units: GLWA's HVAC contractor noted there had been issues with the HVUs which had been resolved. They did not note any out of the ordinary wear or capacity issues with the units.

During Jacobs site investigations (June 2020) the following observations were noted:

- It was observed during the site visit that the air balance of PACU-1 in the Process Building had been adjusted since installation. It is very likely that this adjustment came from a desire to improve thermal comfort in occupied spaces. Additionally, it was noted that the supply air duct from PACU-1 runs from the West side to the East side of the Process Building; however, the return air duct terminates at the entrance to the odor control room (see Figure 9-2 below). This is likely to result in poor air quality as a result of a lack of air circulation in spaces on the East side of the Process Building.

Figure 9-2. PACU-1 Return Air Ductwork

- The doors between the Process Building odor control room and the Work Area were observed to be open. Additionally, ventilation in the odor control room was switched off. Condensation was noted on the PACU-1 supply air duct directly in front of the Odor Control Room.
- Condensation was noted on the floor at the top of the dewatering room (basement) stairway. HVU-4, which serves the dewatering room was supplying ventilation air but EF-7 which provides relief for the air supplied to the dewatering room was not operating despite having its motorized damper in the open position. Additionally, significant corrosion was observed on the body of the dewatering room's duct mounted gas furnace (Figure 9-3).

Figure 9-3. Corrosion on EF-7 Ductwork

- HVU-2's supply fan, which provides ventilation to the odor control room in the Headworks Building, was observed to be running; however, EF-1, EF-2, EF-3 were not operating.

9.2.5.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Process Building Air Balance Study. An air balance is recommended for the Process Building to determine if the heating and cooling issues are the result of a poorly balanced system. It is noted that the operators occasionally leave the door to the odor control room open to cool this area, as observed during the site visit. This may be contributing to the issues related to poor cooling provided by PACU-1. Also, it should be noted that the spaces in the Process Building which are cooled are only designed to be cooled to 78°F.

If the air balance does not improve conditions in the Process Building, extending the return air to PACU-1 should be considered. This should improve air circulation and increase supply air flow to the spaces on the East side of the facility, including the Office.

Scheduled Replacement Plan: As noted in Section 9.2.5.2, many of the relatively small HVAC-related equipment at this facility is recommended to be replaced in-kind. Therefore, it is included in the SRP.

9.2.6 Electrical

9.2.6.1 Description of Existing System

The Hubbell Southfield facility's electrical system consists of one DTE utility feed from a 1,500 kVA, 480 V, 3-phase outdoor transformer (secondary metering) and one diesel generator feed from a 600 kW, 480 V, 3-phase stationary generator. The feeds are connected to a 2,500 A switchboard MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP switchboard also has a 2,000 A breaker before the ATS, which feeds a main circuit breaker panel switchboard (MCBP). The MDP and MCBP have breakers that

feed motor control centers (MCCs) and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 9-14 provides a summary of the major electrical equipment for this facility.

Table 9-14. Major Electrical Equipment at Hubbell-Southfield

Location	Major Electrical Equipment	Description
Electrical Room	Main Switchboard/ATS (MDP)	2,500 A, 480/277 V, 3-Phase
Outdoors	Generator (Diesel)	600 kW, 480 V, 3-Phase
Electrical Room	MCC-P1	600 A, 480/277 V, 3-Phase
Odor Control Room	MCC-H1	250 A, 480/277 V, 3-Phase
Electrical Room	MCC-P2	1,200 A, 480/277 V, 3-Phase
Odor Control Room	MCC-H2	600 A, 480/277 V, 3-Phase

9.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the next section.

9.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project HS-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles, however it will be less safe when operating at night and select locations within the basin.
- 2) **Alternative 2: Electrical Improvements.** Add Lighting and Exterior Power Receptacles at the following locations (and shown on the electrical drawings - Figure HS-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin Nos. 1 and 2—Add interior explosion-proof LED lighting fixtures to provide lighting within the basins.
 - Access road—Add light poles and associated LED light fixtures. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - Outfall area—Add a light pole and overhead lighting at the facility's outfall. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - External lighting on top of Basins—Add light poles and LED lighting fixtures on the facility's basins. Lighting foot-candles shall meet the requirements of the local outdoor lighting ordinances.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including receptacles every 75 ft on top of the basins for maintenance and operational needs.

This project should be incorporated into the flushing gate project (Project HS-FD-1,) if the new basin flushing system moves forward because of the amount of work on and in the basins.

The alternative evaluation is presented in Table 9-15. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$100,000, which is a moderate cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 9-15. Alternative Evaluation for Electrical Improvements (Project HS-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe when operating at night and when accessing select locations within the basin.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 349,000	\$ -	\$ 349,000	\$ 99,714	Not Applicable
	<i>Definition:</i>	Add additional lighting and receptacles at identified locations	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.7 I&C

9.2.7.1 Description of Existing System

Control System: The original control system at Hubbell Southfield was installed in 1996 under PC-694. Since then, several modifications to the original control system have taken place. In 2002 under PC-713, the facility's PLC control system was upgraded to interface with the Ovation system to enable remote monitoring and control the facility from SCC. In 2009, PC-761 replaced the control system and workstations with new Allen Bradley ControlLogix redundant PLCs and new operator workstations with Factory Talk View SE software. The existing hardwired back-up control panel and other miscellaneous PLCs and subsystems are incorporated into the overall control system. The current system is equipped with a back-up radio system to communicate critical monitoring points back to the SCC on wide area network failure.

The current PLC control system and back-up panels are obsolete and do not meet GLWA SCADA Governance standards, which stipulate that all CSO facilities use Ovation workstations with high-performance graphics.

Flow and Level Sensors: Table 9-16 summarizes the level sensors and flow meters at the Hubbell-Southfield CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 9-16. Summary of Flow Meters and Level Sensors at Hubbell-Southfield CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent channel (Upstream of inflatable dams)	2	Transit-Time (AccuSonic)
Shunt Channel (Shunt and bypass)	2	Transit-Time (AccuSonic)
Dewatering Flow	1	Magnetic
CSO Facility Level Sensors		
Influent channel (Upstream of inflatable dams)	2	Ultrasonic
Shunt Channel (Shunt and bypass)	2	Ultrasonic
Screening area (upstream and downstream of bar racks)	2	Ultrasonic
Basins	2	Ultrasonic
Dewatering Wells	2	Ultrasonic
Effluent Channel	1	Ultrasonic
Rouge River	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed	1	Ultrasonic

9.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Evaluate level sensors and flow meters to determine redundancy and identify sensors or meters that could potentially be removed. Jacobs further evaluated this issue and found that the flow meter in the Shunt Channel is redundant to the flow meters for the Bypass Channel and Influent Channel and could possibly be eliminated. Under the current operation of first flush capture, the Shunt Channel flow meter provides the flow

rate for flow to Basin 2 (after Basin 1 is full) and flow to the Bypass Channel (when the Bypass gates are open). Since there is a flow meter on the influent and one on the Bypass, the Shunt Channel flow meter is redundant and could be removed. However, it does provide redundancy if the Influent flow meter fails and it was recently replaced. It is recommended that the Shunt Channel flow meter be considered for elimination when it is near the end of its useful life.

- Need for remote control capability of the Chemical Feed area from the Control Building
- Need for remote control of VR-8 gate. This need is scheduled to be addressed in Spring 2021 by SCC under CS-090A. This project will provide remote control of this gate from either the Hubbell Southfield CSO Basin or SCC.
- Need for local remote control for dewatering pumps
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system to the latest version and increased monitoring capabilities

9.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project HS-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, all of the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements** including,

- Provide remote control capability of the Chemical Feed area from the Control Building
- Provide local remote control for dewatering pumps
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Provide remote control capability of the Chemical Feed area from the Control Building. A Remote I/O panel will be required at the Chemical Feed area which will be connected to the Control Building via a fiber optic cable. The Remote I/O panel will interface with the existing motor starter control circuits to be able to operate the equipment remotely.

Provide local remote control for dewatering pumps. Provide local control for the four Dewatering Pumps in accordance with Section 5.4.9.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 9-17. The sources of costs used in this evaluation are listed in the following bullets:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – I&C Improvements has a total benefit score about 0.3 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M provided by the various I&C improvements. The NPV/Benefit cost for Alternative 2 is \$120,000, which is a moderate cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 9-17. Alternative Evaluation for I&C Improvements (Project HS-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 274,000	\$ 7,000	\$ 421,627	\$ 127,124	Not Applicable
	<i>Definition:</i>	Provide local control capability of the Chemical Feed area from the Control Building; provide local remote control for dewatering pumps; provide tank level indication at Chemical Fill Station; provide process cameras at select locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Control System Upgrade (Project HS-I&C-2). The current facility's PLC control system, network, workstations and control system back-up panels are obsolete and should be replaced in the near future. The control system does not meet GLWA SCADA Governance standards, which require that all CSO facilities use Ovation workstations with new high-performance graphics. GLWA's standards for local CSO facility's control systems can be either the latest Allen Bradley PLC system with Ovation workstations or a complete Ovation system. This approach is being used on an ongoing project at Leib, Seven Mile, and St. Aubin.

Because of the approach used on the ongoing project, there is only one overall control system alternative considered. The project should include decommissioning and removal of the original hardwired back-up local control panels. These local panels are no longer required with today's redundant control system processors and local Operator Interface Terminal (OIT) as local back-up to the facility's workstations.

Table 9-18 provides the summary of the **Control System Upgrade, which is the recommended alternative**. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Consideration should be given to replacing various field instruments; however, these are not included in the capital costs.

Table 9-18. Alternative Evaluation for Control System Upgrade (Project HS-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 2,457,000	\$ -	\$ 2,457,000	\$ 819,000	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.8 Site

9.2.8.1 Description of Existing Site

The Hubbell-Southfield CSO Facility was constructed in 1994. The Hubbell-Southfield facility has two buildings situated on top of the basin, namely the Headworks Building over the north influent end of the basin and the Process Building over the dewatering pumps at the center of the basin. The access entrance to the site is through a 24-ft wide sliding vehicular gate. Security around the perimeter of the site is provided by an 8-ft high chain link fence. Site pavement consists of 9-in. reinforced concrete on undisturbed earth. There are no sidewalks near the basin. The access road from Rotunda Dr. to the basin consists of 10-in. asphalt on 12 in. of gravel base.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

9.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- The existing 2-in NPW header line for flushing the basins provides insufficient pressure for washdown after storm event.
- Poor condition of the service drive around the basin
- Localized ponding of water on the basin surface. In the winter, this water freezes and causes safety concerns
- Poor condition of security fencing
- The detention ponds drainage from the gold course discharged over the access road creates an issue for GLWA vehicles driving through
- The following needs are generally preventative maintenance items intended to ensure that the site features or utilities are serviceable throughout their expected service lives.
 - Remove vegetation from the fence line around the perimeter of the basin
 - Re-caulk expansion joints at the base of the exterior walls around the Headworks and Control Buildings
 - Replace expansion joint membranes and expansion joint cover plates on the basin service drive.

9.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Flushing Water Pressure in Headworks Area (Project HS-Site-1). A 6-in. watermain services the Headworks Building and supplies the NPW service to the hose bibs in the basin. The 6-in. watermain is tapped from an 8-in. watermain outside of Headworks Building. The NPW is supplied through a 2-in. header that runs through the length of the basin with drop connections at hose bibs spaced approximately 100 ft apart. GLWA Operations staff

indicate that there is little pressure in the 2-in. NPW line for hose washdown inside the basin after a storm event. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area.** To increase pressure in the NPW line, it is recommended to demolish and replace approximately 950-ft of the existing 2-in. header in the basin with a 4-in. header (See Figures HS-SITE-1-ALT-2). The size of this header should be confirmed during detailed design.

The alternative evaluation is presented in Table 9-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$33,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area, is the recommended alternative.**

Table 9-19. Alternative Evaluation for Flushing Water Pressure in Headworks Area (Project HS-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Insufficient water pressure for washdown after storm event.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	Health and Safety	3	3.42	\$ 112,000	\$ -	\$ 112,000	\$ 32,780	Not Applicable
	<i>Definition:</i>	To increase the pressure in the non-potable water line, it is recommended to replace the existing 2" header with a 4" header in the basin.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier washdown	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Site Improvements (Project HS-SITE-2). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Resurface Service Drive Around Basin
 - Improve Basin Roof Surface Drainage
 - Replace Security Fencing
 - Culvert for Golf Course Drainage

Each of the site related improvements listed above are described further below:

Resurface Service Drive Around Basin: The existing service drive around the basin is in poor condition. The service drive along the east side of the basin consists of reinforced concrete slab, which is the roof of the Dearborn Channel and Shunt Channel. The remaining portion of the service drive that runs across the basin and then along the west side of the basin to the headworks building consists of 4-in. concrete topping reinforced with welded wire fabric (WWF) on top of double tee beams of the basin roof.

To restore the service drive along the east side, it is recommended to hydro-demolish the top surface of the Dearborn and Shunt Channels roof slab up to 2 in. below the top layer of reinforcement and reconstruct the slab. To restore the service drive across the basin and along the west side of the basin, it is recommended to hydro-demolish the entire 4-in. thick concrete topping and replace it with new air entrained reinforced concrete topping. The reconstruction of the slab along the east and west sides of the service drive should be sloped to provide drainage away from the structure and towards grassy areas.

It is noted that the hydro-demolition and reconstruction activities will require a temporary support system from below to maintain the integrity of existing structural systems (roof slab/double Tees) during construction activities. Representative concrete core samples should be taken and tested by a material testing company to check the integrity of the slabs prior to any demolition activities.

Improve Basin Roof Surface Drainage: There are numerous areas on the basin roof surface where localized ponding of water occurs (See Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B). Ponding of water can become a safety issue for personnel who must navigate around these areas to access equipment or facilities during winter months when the surfaces turn to ice. It is recommended at the larger areas of ponding water that cores be made through the basin roof to drain the area. Recessed plaza deck drains should be installed in the cored holes to drain ponded water directly to the basin. As an alternative, to prevent stormwater from entering the basin, consideration could be given to piping the ponded water drainage on the underside of the basin through the basin exterior walls and discharge to drainage swales on either side of the basin. It is estimated that there are 10 to 15 significant sites of ponded water on the basin surface.

Replace Security Fencing: There are two locations where fencing needs to be replaced because it is in disrepair:

- The fencing at the entrance to the service drive from Rotunda Drive (see Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B, for location). The fencing extends on the south side of the service road from Rotunda Drive to the gate on the service drive at the Tournament Players Club golf course maintenance building. This includes 360 ft of 5-ft tall cyclone fencing.
- The fencing on the north side of the access road from Rotunda Drive to the facility access gate (also shown in Figure HS-SITE-2-ALT-2 in Volume 6 – Appendices, Appendix B). This includes approximately 2,300 ft of 5-ft tall cyclone fencing.

It should be noted that the as-built drawings for this facility (PC-694) do not include fencing. As such, it appears the fencing was existing when the facility was built and may not be the responsibility of GLWA.

Culvert for Golf Course Drainage: Periodically, the Tournament Players Club golf course must drain detention ponds located on the course. This is generally accomplished by pumping pond contents through hoses and discharging over the access road to allow the water to drain to the Rouge River. To minimize soil erosion from this method of pumping, GLWA has proposed to create a drainage culvert beneath the access road so that the pond water can be discharged beneath the road rather than across its surface where it is tracked by GLWA vehicles. The new drain should be located beneath the access road in the vicinity of the Tournament Players Club Maintenance Building and should include a catch basin on the north side of the road and a rip rapped discharge with a headwall (or spillway) on the Rouge River side of the access road.

The alternative evaluation is presented in Table 9-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety, and ease of O&M. The NPV/Benefit cost for Alternative 2 is \$258,000. **Because of the improved drainage and safety and restoration of the road with Alternative 2 – Site Improvements, Alternative 2 is the recommended alternative.**

Table 9-20. Alternative Evaluation for Site Improvements (Project HS-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>		Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 902,000	\$ -	\$ 902,000	\$ 257,714	Not Applicable
	<i>Definition:</i>	Resurface Service Drive Around Basin; improve basin roof surface drainage; replace security fencing; culvert for Golf Course drainage	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved drainage & improved safety for accessing facility.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.9 Architectural

9.2.9.1 Description of Existing Facilities

The Hubbell-Southfield CSO Facility consists of Headworks Building and Process Building. The Headworks Building includes a screen room, chemical room, a mechanical room and an odor control room. The Process Building includes a control room, utility support (electrical and mechanical), odor control room, and other miscellaneous rooms. The facility also includes the retention basin.

9.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 9-21. As such, the roof should be replaced in-kind and the costs and schedule for the roof replacement will come from the SRP.

Table 9-21. 60-Year Life Cycle Cost Evaluation of Shingled vs. Metal Roof for Hubbell-Southfield Facility

	Shingle Roof	Metal Roof
Replacement Cost ¹	\$282,000	\$940,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life Cycle Cost (NPV) Discounted at 2.4%	\$766,000	\$940,000

¹ Based on 18,800 ft² roof area; \$15 ft² for shingle roof and \$50/ft² for metal roof.

CS-299 Architectural Assessment: Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

9.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (HS-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Install floor expansion joint in Process Building
 - Paint wood truss and plywood roof deck in Process Building
 - Remove corrosion on bollards, and clean and coat
 - Remove existing paint, clean and paint wood roof deck and framing
 - Install vertical expansion joint and repair concrete and wall in Headworks Building
 - Replace damaged/stained/missing acoustic ceiling tiles in Process Building
 - Address door hardware issues
 - Caulk gap of fascia board on Process Building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure HS-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 9-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 9-22. Alternative Evaluation for Architectural Rehabilitation (Project HS-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 371,000	\$ -	\$ 371,000	\$ 119,677	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.10 Safety

9.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

9.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 9-23. The capital improvement project to address these issues is included in the table.

Table 9-23. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Headworks	Mid-rail missing between bar screen 2 and 3	Add mid rail	Safety Improvements (Project HS-SAFE-1)
Basin Odor Control Room	At top of ladders, mid-rail chain needed	Add swing gate (original recommendation was to add chain; however, this is no longer current GLWA practice)	Safety Improvements (Project HS-SAFE-1)
Process Building Odor Control Room	Eyewash 0922552 too low	Adjust height of eyewash	Eyewash/Shower Improvements (Project HS-SAFE-1)
Basin Odor Control Room	Eyewash 0947279 too low	Adjust height of eyewash	Eyewash/Shower Improvements (Project HS-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project HS-SAFE-1)

9.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project HS-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing between bar screen #2 and #3 to eliminate fall hazard
- Add swing gate at top of ladders in the basin odor control room
- Adjust height of eyewash in the Process Building odor control room and basin odor control room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 9-24 shows the one alternative.

Table 9-24. Alternative Evaluation for Safety Improvements (Project HS-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 158,000	\$ -	\$ 158,000	\$ 41,762	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

9.2.11 Supporting Infrastructure

9.2.11.1 Description of Existing System

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above.

9.2.11.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the following section.

- The VR-8 Regulator upstream of the Hubbell-Southfield CSO Facility is located in the center median of Michigan Avenue east of the Southfield Freeway. The VR-8 Regulator consists of two stainless steel slide gates that are adjusted by SCADA control to regulate flow from the Hubbell-Southfield sewer to the NWI. A rehabilitation project was designed in 2013 by Metco, but not implemented. Rehabilitation of the VR-8 Regulator is still needed. It should be noted that the control system for the regulator is being upgraded in early 2021 under Project No. CS-090A. This upgrade will provide remote control of the two regulator gates from the Hubbell Southfield CSO Facility or SCC.

9.2.11.3 Discussion and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

VR-8 Regulator Rehabilitation (Project HS-SUPP-1). As described in the 2013 Final Basis of Design Report by Metco, the rehabilitation of the VR-8 Regulator included 1) Replacement of the slide gates and actuator; 2) SCADA system modifications; and 3) Access improvements in the median near the gates and control panel. As noted above, the SCADA system modifications are being addressed as part of a control system project. As such, Jacobs based the proposed rehabilitation on the cost estimate generated for this project (inflated to current dollars), excluding the SCADA system improvements. It was noted in the Metco report that the access improvements using geoblock units had not been approved by the Michigan Department of Transportation. These details would need to be resolved during detailed design.

The alternative evaluation is presented in Table 9-25. The capital cost is included in Volume 6 – Appendices, Appendix C under this project title. Since this is rehabilitation of an existing system, there is only one alternative considered. As such, **Alternative 1 is the recommended alternative.**

Table 9-25. Alternative Evaluation for VR-8 Regulator Rehabilitation (Project HS-SUPP-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	VR-8 Regulator Rehabilitation	Health and Safety	3	3.00	\$ 1,956,000	\$ -	\$ 1,956,000	\$ 652,000	Best Value Alternative
	<i>Definition:</i>	Replacement of the slide gates and actuator; and access improvements in the median.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Maintains system reliability and functionality.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

9.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Hubbell Southfield CSO facility, Table 9-26 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 9-26, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 9-26. Listing of Asset Condition Assessments for Hubbell Southfield Facility

Asset Type	Total No. of Assets in Asset Type	# of Visual Condition Assessments	# of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is not an asset. Another one of the building asset listed as "PLANNING - ORDERING PARTS/FILLING OUT WORK ORDER/COMPLETING INVENTORY OF PARTS ON HAND. (FOR ELECTRICIANS, MILLWRIGHTS and PLUMBERS ONLY)", which is also not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Two pumps are listed in WAM - Basin 1 Sample Pump and Shunt Channel Sample Pump. These umps are being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Hubbell-Southfield Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

9.3 Capital Planning for Hubbell-Southfield CSO Facility

9.3.1 Summary of Capital Improvement Plan Projects

Table 9-27 provides a summary of the recommended CIP projects and associated capital costs for the Hubbell Southfield CSO facility based on the alternative evaluations conducted for this facility.

Table 9-27. Summary of Recommended Projects at Hubbell-Southfield CSO Facility

Project No.	Alternative	Description	Total Project Cost
HS-SCR-1	2	Screening Improvements	\$ 195,000
HS-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 534,000
HS-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
HS-DIS-3	2	Add a New Chemical Storage Tank	\$ 753,000
HS-FD-1	3	New Basin Flushing System	\$ 24,800,000
HS-FD-2	2	Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System	\$ 950,000
HS-FD-3	2	Provide Equipment Access to Effluent Channel	\$ 126,000
HS-ELEC-1	2	Electrical Improvements	\$ 349,000
HS-I&C-1	2	I&C Improvements	\$ 274,000
HS-I&C-2	1	Control System Upgrade	\$ 2,457,000
HS-HVAC	N/A	Process Building Air Balance Study	\$ 5,000
HS-SITE-1	2	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	\$ 112,000
HS-SITE-2	2	Site Improvements	\$ 902,000
HS-ARCH-1	2	Architectural Rehabilitation	\$ 371,000
HS-SAFE-1	1	Safety Improvements	\$ 158,000
HS-SUPP-1	1	VR-8 Regulator Rehabilitation	\$ 1,956,000

9.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 9-28. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 9-28. Capital Improvement Plan Projects for Hubbell-Southfield CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
HS-1 Disinfection System Improvements	\$ 1,507,000	2029 <i>Timing based on asset condition</i>	HS-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 534,000
			HS-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
			HS-DIS-3	Add a New Chemical Storage Tank	\$ 753,000
HS-2 Flushing System Improvements	\$ 27,239,000	2026 <i>Timing based on safety issues</i>	HS-FD-1	New Basin Flushing System	\$ 24,800,000
			HS-FD-2	Upgrade Basin Dewatering Pumps and Reinstall Sump Pumps and Fluidization System	\$ 950,000
			HS-FD-3	Provide Equipment Access to Effluent Channel	\$ 126,000
			HS-ELEC-1	Electrical Improvements ^a	\$ 349,000
			HS-SITE-1	Increase Flushing Water Pressure and Add Hose Bibs in Headworks Area	\$ 112,000
			HS-SITE-2	Site Improvements ^b	\$ 902,000
HS-3 Facility-Wide I&C Improvements	\$ 2,731,000	2029 <i>Timing based on asset condition</i>	HS-I&C-1	I&C Improvements	\$ 274,000
			HS-I&C-2	Control System Upgrade	\$ 2,457,000
HS-4 VR-8 Regulator Rehabilitation	\$ 1,956,000	2030 <i>Timing based on best judgment</i>	HS-SUPP-1	VR-8 Regulator Rehabilitation	\$ 1,956,000
HS-5 Facility-Wide Safety and Architectural Improvements	\$ 529,000	2023 <i>Project should be initiated as soon as possible</i>	HS-ARCH-1	Architectural Rehabilitation	\$ 371,000
			HS-SAFE-1	Safety Improvements	\$ 158,000

Notes:

^a Electrical Improvements were combined with Flushing System Improvements because most of electrical improvements are related to lighting within and on top of basin.

^b Site Improvements were combined with Flushing System Improvements because road around basin will likely need to be repaired after construction.

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 9-29 and Table 9-30 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 9-29 indicates that HS-DIS-1 project has 12 assets that has an average condition score of 1.57 and an average replacement date of 2029. This information was used to propose a scheduled construction completion date of 2029.

Table 9-29. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
HS-DIS-1	12	1.57	1.57	2.86	12	2029	\$ 969,900
HS-FD-2	3	1.57	1.20	2.51	20	2039	\$ 302,100
HS-I&C-1	4	1.14	1.23	1.85	14	2033	\$ 447,179
HS-I&C-2	3	2.29	1.57	4.08	12	2029	\$ 1,481,175

Table 9-30. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
HS-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
HS-FD-2	3	1.38	5.00	4.83	20	2021	\$ 126,900
HS-I&C-1	0	0.00	0.00	0.00	N/A	N/A	\$ -
HS-I&C-2	0	0.00	0.00	0.00	N/A	N/A	\$ -

There is a recommended capital improvement project presented in Table 9-28 that could be better delivered under capital outlay projects. This project is listed in the following bullet:

- Screening Improvements (HS-SCR-1)

9.3.3 20-Year Capital Outlay Plan

Table 9-31 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 9-31. 20-Year Capital Outlay Plan for Hubbell-Southfield CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 461,382	\$ 7,482	\$ -	\$ -	\$ -	\$ 453,900	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -

2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 16,625,877	\$ 1,624,841	\$ 415,392	\$ 1,737,978	\$ 2,254,175	\$ 1,681,038	\$ 949,321	\$ 1,258,781	\$ 3,907,263	\$ 1,876,308	\$ 310,560	\$ 488,428	\$ 121,792

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Influent slide gate (ISG-2) received a score of 5 at the time of the Condition Assessment since the actuator was on the ground and not mounted to the gate.
- Pumping System: Flushing Water Pump (FWP-2; \$327,000) received a score of 5 since the unit was out of service at the time of the Condition Assessment. Dewatering Pump No. 4 (\$100,700) was not functional during electrical testing at the time of the assessment. The two immersible sump pumps (ISMP-1 and 2; \$13,100 each) have been removed from service for some time.

10. Leib CSO Control Facility

10.1 General Facility Description and Future Capacity Considerations

10.1.1 General Facility Description

The Leib CSO Facility is an SDF with 9.9 MG of storage, and a treatment capacity of 1,550 cfs. It was constructed in 2002. The facility has a nearly 1-mile long effluent conduit used for disinfection contact time before discharge into the Detroit River. The facility consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground outfall vault.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

10.1.2 Future Capacity Considerations

The WWMP recommended projects to increase wet weather flows to existing CSO facilities to maximize the use of the facilities and minimize the construction of additional facilities. Many of the CSO facilities do not reach their design flows, so there is an ability to accept additional flows, without exceeding their design capacity.

The Meldrum Diversion Sewer to the Leib CSO Facility is one of the recommended projects from the WWMP that will increase flows to the existing Leib CSO facility. The magnitude of the increased flows and the potential impact on screening and disinfection performance is described below.

This project originated from the WWMP and involves diverting the Meldrum sewer to the Leib CSO facility by constructing 350 ft of 5-ft diameter diversion sewer along Waterloo just upstream of the Leib facility. See Figure 10-1 for the layout of this new diversion sewer. The Leib CSO facility was designed to treat 1,550 cfs and hydraulically pass 2,000 cfs. The design hydraulic grade line (HGL) conditions are between elevation 110.5 and 111.5 ft, with a peak hydraulic capacity of 2,000 cfs, and a Toward Treatment Sewer capacity limited to 150 cfs.

Figure 10-1. Layout of Proposed Meldrum Sewer Diversion near the Leib CSO Facility

The Regional Wastewater Collection System Model was used during the WWMP to predict the change in hydraulic grade line for the Leib facility for the 10-year 24-hour storm event. The WWMP reports that the 10-year 24-hour storm will add a peak flow of 427 cfs, and the HGL within the Leib CSO facility will stay within the critical elevation of El 589.72 (109.97 Detroit datum) at the crown of the Conant Mt. Elliot Sewer.

10.2 Facility Assessment

10.2.1 Screening

10.2.1.1 Description of Existing System

The Leib CSO Facility has two types of screens: 1) raked horizontal bar screen (original manufactured by COPA) and 2) raked vertical bar screens (manufactured by ROMAG). Constructed in 2002, the facility was intended to be a full-scale pilot facility for this type of fine screen. There are four screening channels in the facility, with a total of eight COPA screens and a total of four ROMAG screens.

During dry weather, raw sewage is routed through the facility and to the Toward Treatment Sewer. During wet weather events, the flow increases, and the flow enters the screening channels as the wet weather flow exceeds the capacity of the Toward Treatment Sewer.

Screenings are retained in the screening channels during the storm. After the storm event, the screenings are conveyed to the Toward Treatment Sewer and then the DRI for eventual removal at the WRRF.

The COPA screens recently received a complete overhaul in 2019. The existing ROMAG screens were also rebuilt in 2019; however, the control panels and power packs were not upgraded.

Table 10-1 provides an overview of the existing screening system at Leib CSO facility.

Table 10-1. Overview of Existing Screening System Leib CSO Facility

Parameter	Value	
Treatment Capacity (cfs)	1,550	
No. of Screens	4 (2 in each of 2 channels)	8 (4 in each of 2 channels)
Manufacturer	Westech ROMAG	COPA
Screen Type	Raked Vertical Bar Screen	Raked Horizontal Bar Screen
Opening Size	4-mm spacing	4-mm spacing
Depth or Length	29 ft 6 in	17 ft 0 in
Width	4 ft 0 in	4 ft 0 in
Screen Cleaning	Mechanical Comb	Mechanical Comb
Screening Removal	Conveyed to Toward Treatment Sewer and then to WRRF	

10.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- ROMAG screens are preferred over COPA for future screens: The screens at the facility are a combination of ROMAG vertical screens and COPA horizontal screens. Having dissimilar maintenance and operating characteristics presents a challenge for the GLWA O&M staff. In consideration that this facility was intended to be a "pilot" facility testing different technologies, it is reasonable to conclude, as it approaches 20-years in age, that some technologies should win out over others. In the case of the screens, the ROMAG screens present the simpler and easier O&M characteristics and therefore standardizing on these screens at this time, when major maintenance or rehabilitation is in the future for both screens, makes sense.
- The ROMAG screens offer a hydraulic benefit of allowing peak flows to overflow the top of the screen (this is not possible with the COPA screens). Although the portion that overflows does not receive screening, it does provide a hydraulic bypass for peak flows so that the screens are not overloaded or damaged. This is an important feature with the addition of the Meldrum Diversion Sewer in the near future.

10.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Screen Replacement (Project LIEB-SCR-1). The ROMAG screens present the simpler and easier O&M characteristics and therefore standardizing on these screens at this time makes sense. There are two alternatives with this option:

- Alternative 1: Replace Existing COPA Screens In-Kind.** This alternative would replace the existing eight COPA screens in-kind.

2) **Alternative 2: Replace Existing Screens with ROMAG Screens.** This project would replace the existing eight COPA screens with four ROMAG screens (Model RSW12x8/4) to make all the screens similar at the facility. The following modifications would be required for the replacement:

- **Structural Modifications:** A notch will need to be created in the channel concrete wall that the ROMAG screen will rest on, to match the existing ROMAG screen design.
- **Control Panel Upgrades:** The new ROMAG screens have new standard sequence of operations, updated electrical devices and controls. The controls for the existing ROMAG screens should be upgraded with these new items, as follows:
 - A touch screen operator interface to provide better functionality to adjust various setpoints.
 - New control functions including short stroke, blocked carriage, pressure settings in each direction, repeat cycle timer, park at home positioning, and level on and off settings.
 - The solenoid valve used on the carriage on the existing ROMAG screens should be replaced with an electrically actuated valve which changes the valve position according to the pressure setting that is seen by the cylinder. The new ROMAG screens will come with the electrically actuated valve used on the carriage.
 - The sequence of operation should be changed to eliminate the intermittent operation of the rake, which would maximize the cleaning frequency regardless of the liquid level once the screen is activated.
 - An ambient temperature thermostat should be installed and when the ambient temperature reaches less than 35°F, the control sequence to cycle the oil weekly would be disabled during periods of freezing temperatures. This will avoid a fault condition when the materials stuck to the screens freeze during winter months.

The alternative evaluation is presented in Table 10-2. The sources of costs used in this evaluation are listed below:

- Capital costs for Alternative 1 were obtained from the screen replacement costs of the SRP.
- Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.
- Although there are O&M benefits to having all the same screens (i.e., similar spare parts and needed familiarity with only one screen type), the difference in O&M costs for the COPA and ROMAG is difficult to monetize. As such, O&M costs are not included in this analysis. This issue, however, is reflected in the Ease of O&M scores.

This evaluation shows that Alternative 1 is the Best Value Alternative. Because of the large difference in capital costs between the two alternatives, **Alternative 1 - Replace Existing COPA Screens In-Kind is the recommended alternative.**

Table 10-2. Alternative Evaluation for Screen Replacement (Project LEIB-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace COPA Screens In Kind	Health and Safety	3	2.78	\$ 3,524,000	\$ -	\$ 3,524,000	\$ 1,266,108	Best Value Alternative
	<i>Definition:</i>	Replace In Kind	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Need to maintain two different types of screens.	Component Performance	3						
	<i>Comments:</i>	Note: This is only replacing the COPA screens with COPA screens. The existing ROMAG screens are not included.	O&M Ease	2						
2	<i>Alt. Name:</i>	Replace Existing COPA Screens with ROMAG Screens	Health and Safety	3	3.55	\$ 6,224,000	\$ -	\$ 6,224,000	\$ 1,753,239	
	<i>Definition:</i>	Replace Existing COPA Screens with ROMAG Screens	Water Quality & Compliance	3						
	<i>Adv.:</i>	ROMAG screens offer a hydraulic benefit of allowing peak flows to overflow the top of the screen. Also, all screens would be identical, making maintenance and spare parts more efficient	Capacity Enhancement	4						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	Note: This is only replacing the COPA screens. The existing ROMAG screens are not included.	O&M Ease	5						

10.2.2 Disinfection

10.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, six low-rate diaphragm pumps, two high-rate centrifugal pumps, four disinfectant rapid mix zones, and 18 induction mixers. There are two channels with four ROMAG screens and two channels with Copa screens discharging into a screened effluent channel. From there screened effluent flows to four disinfectant rapid mix zones. There are four induction mixers per disinfectant rapid mix zone consisting of one pair of mixers upstream and one pair of mixers downstream of a concrete baffle wall that directs all flow down and past the mixers. There are also two induction mixers in the influent channel upstream of screening referred to as prechlorination mixers. Four of the low-rate sodium hypochlorite pumps are each paired to a disinfectant rapid mix zone. Flow is metered from each pump and then flow is split in a manifold to the four induction mixers in each disinfectant rapid mix zone. The manifold includes a solenoid valve, manual valve, and a sight flow indicator to each induction mixer. Flow splitting between induction mixers is primarily dependent on equal back pressure valve settings to the induction mixers. The other two low-rate sodium hypochlorite pumps are each paired to one of the influent channel mixers. The two high-rate pumps discharge to a four-way manifold with flow metering on each branch. These tie into the discharge from the four low-rate pumps upstream of the manifold to each disinfectant rapid mix zone. There are also valved connections allowing the high-rate pumps to be used for the influent channel induction mixers.

The design which was intended to provide redundancy and flexibility is atypically complex and results in the manifolds including valves and sight flow indicators to be inaccessible due to their height on the wall. Table 10-3 provides an overview of the existing disinfection system at Leib CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G

Table 10-3. Overview of Existing Disinfection System at Leib CSO Facility

Parameter	Value
Treatment Capacity (cfs)	1,550
Design Feed Strength (% hypochlorite)	7.5
Max. Dosage at Design Flow (mg/L Cl ₂)	38
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	10,450
Type	FRP
Pumps	
Number	8 Total; 6 low-rate, 2 high-rate
Capacity (gpm)	Low-rate: 7.6, High-rate: 112
Type	Low-rate: Diaphragm, High-rate: Centrifugal
Mixers	
Number / Type	18 / Chemical induction mixers
Model Number / hp / Manufacturer	SWC15FX / 15 hp / Water Champ

10.2.2.2 Identified Needs and Issues

The needs and issues identified for Leib were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are listed in the following bullets :

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Leib chemical feed system has the following issues:
 - Pumps are expensive to maintain and replace
 - Complex piping with a high number of components
 - Inaccessible manifold components due to height on wall
 - The VFDs and electrical equipment are located in the corrosive environment of the chemical room
 - The chemical feed pump and motor are difficult to remove from the containment area
 - Currently, a hose must be moved and connected to each pump suction pipe to flush the hypochlorite solution from the feed system with NPW. A hard-piped flushing water connection is desired so that flushing could be accomplished by opening a valve to each pump.
 - The chemical room floor has been damaged due to a chemical leak from one of the storage tanks.

These issues are addressed in Replace Chemical Feed System (Project LEIB-DIS-1) below.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project LEIB-DIS-2) below.
- There are 18 chemical induction mixers that require relatively frequent and costly maintenance. This issue is addressed in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project LEIB-DIS-3).

10.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project LEIB-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, LEIB-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

Each of the alternatives above would include provisions to address the additional concerns specific to the Leib feed system:

- For cost estimating purposes, water piping and valving to each feed pump was assumed to allow water flushing for the entire chemical feed system from the feed pumps to the mixers.
- Move VFDs and electrical equipment out of the chemical room.
- For cost estimating purposes, a mast type jib crane (similar to the one described for Conner Creek) is assumed for moving the pumps and motors up and down the flight of stairs. The actual configuration should be included in the detailed design of a modified chemical feed system.

The alternative evaluation for these alternatives is presented in Table 10-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP and include pump replacement at Year 10.
- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on manufacturer pump rebuilds at a cost of \$20,000 per year and GLWA onsite rebuilds at a cost of \$24,000 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 10-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 10-4. Alternative Evaluation for Replace Chemical Feed System (Project LEIB-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 1,262,400	\$ 44,000	\$ 2,190,344	\$ 1,051,365	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 1,724,000	\$ 26,750	\$ 2,288,148	\$ 635,597

	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project LEIB-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Operation in manual at Leib is noted by operations as being extremely difficult. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The influent flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on influent flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the facility to analyze TRC concentrations to further adjust chemical feed flows.

The sample point should be located approximately 15 minutes travel time downstream of the dosing point at average flow but peak flow travel time and the future additional flow from Meldrum diversion must also be considered. The exact location would be determined during design. The original design included a sample pump about 50 ft from the mixing chamber. The appropriateness of this location should be evaluated during design. However, the operability of this pump is not known because it is not currently used for sampling. Given the uncertainties regarding whether this sample point and the condition of the sample pump, the cost for a new manhole to access a sampling pump in the effluent conduit was included. A buried pipe was assumed in the cost estimate to convey the sample flow into the existing building where the TRC analyzer would be located.

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 10-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 10-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project LEIB-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common at CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	O&M to maintain analyzers based on 4 hrs/month.	O&M Ease	2						

Reduce Cost Associated with Large Quantity of Chemical Induction Mixer (Project CON-LEIB-3). Plant personnel report that the mixers are expensive to maintain and due to the sealed nature of submersible mixers they must be sent back to the manufacturer for maintenance which adds shipping cost and takes months before the mixer is returned to service. The Leib facility has 16 chemical induction mixers in the mixing channels (and 2 pre-chlorination mixers, which would remain). A reduction in the number of mixers would reduce maintenance and the associated expense proportionate to the reduction. It would also reduce the complexity for equal flow splitting between mixers.

The alternatives to address this issue were identified previously in Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Section 5.2.4); however, due to facility constraints, vertical shaft mixers would not be feasible at this location, so that option is not included. The alternatives include:

- 1) **Alternative 1. Replace Existing Chemical Induction Mixers In-Kind.** This alternative assumes replacement of the mixers in-kind.
- 2) **Alternative 2. Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers.** Computation fluid dynamic (CFD) modeling is assumed to be required to demonstrate to EGLE the adequacy of a lesser number of mixers. For illustration purposes, it is assumed that the number of mixers can be reduced by half (i.e., from four to two per channel). This needs to be confirmed by collection system modeling performed by others. Capital and O&M costs per mixer are identical to Alternative 1.

The alternative evaluation is presented in Table 10-6. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternatives 1 and 2 includes mixer replacement in-kind at the number of mixers shown. Capital costs are based on the SRP replacement cost of \$50,000 per mixer and a 10-year life. Because the life-cycle period is 20 years, the capital costs assume replacement of the mixers twice during the 20-year period.
- For Alternative 2, the cost of the CFD model is assumed to be \$50,000.
- The O&M costs for mixer replacement in Alternatives 1 and 2 is based on current costs for repairing a chemical induction mixer. It is assumed the mixer needs to be repaired every 2.5 years at a cost of \$15,500 per mixer.

This evaluation shows that Alternative 2 – Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers is the Best Value Alternative. As such, **Alternative 2 – Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers is the recommended alternative.**

It should be noted that the cost of the reduced number of mixers is not a new capital improvement cost for GLWA. Rather, it was used in this evaluation to compare alternatives. The cost for the CFD modeling would likely be included in a capital outlay, not a capital improvement project. If the CFD modeling does not prove that disinfection performance can be achieved, the number of mixers would remain the same as the current number.

Table 10-6. Alternative Evaluation for Reduce Cost Associated with Large Quantity of Chemical Induction Mixers (Project LEIB-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace Existing Mixers in-kind	Health and Safety	3	2.57	\$ 1,600,000	\$ 84,800	\$ 3,388,401	\$ 1,320,156	
	<i>Definition:</i>	Replace existing mixers as required.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, lots of redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Expensive and impacts operations and maintenance. Equipment installed in basins.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	Health and Safety	3	3.00	\$ 850,000	\$ 42,400	\$ 1,744,200	\$ 581,400	Best Value Alternative
	<i>Definition:</i>	Perform computational fluid dynamics (CFD) model of basin and determine required number	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system, maintains required redundancy.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less expensive and less impacts to operations and maintenance. Equipment installed in	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.3 Odor Control

There is no odor control system at the Leib facility. Building space for a carbon adsorber system, space in the electrical room for the fan motor, and a duct penetration to the screening facility below grade were provided, if odor control is needed in the future. However, odor complaints have not been received for this facility since it has been in operation. Therefore, an odor control system is not needed and, therefore, there are no associated "needs."

10.2.4 Flushing and Dewatering

10.2.4.1 Description of Existing System

The Leib CSO Facility does not have a dedicated dewatering or flushing system for the screening and disinfection area. The facility drains by gravity and, due to the limited use, solids accumulation has not been a major issue at this facility, with the exception of the screening channels, which are discussed in the next section.

The outfall conduit has dewatering pumps to dewater the lower portion of the effluent conduit. These pumps are located near the Outfall Sample Building. The dewatered flow is pumped to the DRI.

Table 10-7 provides an overview of the existing flushing and dewatering system at Leib CSO facility.

Table 10-7. Overview of Existing Flushing and Dewatering System at Leib CSO Facility

Parameter	Value
Headworks Dewatering and Flushing System	Headworks (basin) area is dewatered by gravity to the Toward Treatment sewer or disinfection conduit.
Effluent Conduit Dimensions	16-ft-dia. effluent sewer to Junction Chamber, two 11-ft-dia. pipes to dewatering gate, two 10 ft × 10.5 ft box conduits to Detroit River
Effluent Conduit Dewatering and Flushing System	- Two 1,500 gpm dewatering pumps located near Effluent Sample Building are used to dewater lower end of effluent conduit. Flow is pumped to the DRI - There is no flushing system in the effluent conduit.

10.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Flushing the screening channels after every storm event is difficult and time-consuming.
- The existing four screening channels cannot be isolated from the influent flow during rehabilitation or extensive maintenance activities. Jacobs reviewed options to install stop logs or sluice gates at the influent end of each channel. Although there is space for new slots to be constructed for either a new gate or stop logs, the lack of isolation of each screen channel from another channel downstream of the proposed gate would not provide the desired isolation. As such, there does not appear to be a feasible way to isolate channels. The current practice of installing scaffolding in the screen channels appears to be the best alternative.

10.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Screening Chamber Flushing (Project LEIB-FD-1). The screening channels must be manually sprayed down after every event. Flushing from the surface is somewhat difficult and time-consuming. There are two alternatives for addressing this issue:

- 1) **Alternative 1: Do Nothing.** Continue manual flushing.
- 2) **Alternative 2: Screening Chamber Flushing System.** A new flushing system piped from the existing NPW line, extending down to the screen channel floors and drilled with holes through the HDPE pipe is recommended to address this issue. Figure LEIB-FD-1-ALT-2, included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

The alternative evaluation for these alternatives is presented in Table 10-8. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 includes GLWA labor cost. It is based on 2 hours per event and 25 events per year, at \$100 per hour rate.
- It is assumed that the cost of water is similar between the two alternatives, so it is not included in this evaluation.

This evaluation shows that Alternative 2 – Screening Chamber Flushing System, is the Best Value Alternative. **As such, Alternative 2- Screening Chamber Flushing System is the recommended alternative.**

Table 10-8. Alternative Evaluation for Screening Chamber Flushing (Project LEIB-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.57	\$ -	\$ 5,000	\$ 90,228	\$ 35,154	
	<i>Definition:</i>	Do Nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>		Capacity Enhancement	3						
	<i>Disadv.:</i>	Flushing from the surface is somewhat difficult and time-consuming	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Screening Chamber Flushing System	Health and Safety	3	3.43	\$ 16,000	\$ -	\$ 16,000	\$ 4,660	Best Value Alternative
	<i>Definition:</i>	A new flushing system piped from the existing NPW line, extending down to the screen channel floors and drilled with holes through the HDPE pipe	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less time to clean channel	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

10.2.5 HVAC

10.2.5.1 Description of Existing System

The Leib CSO facility consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground influent channel. Table 10-9 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, and emergency eyewash shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 10.2.10.

Table 10-9. Major HVAC Equipment at Leib CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks (Screening Chamber)	SF-1	Supply Fan	59,000 CFM
Chemical Room	HV-2	AHU	2,700 CFM 300 MBH
	EF-2	Exhaust Fan	3,010 CFM
Electrical Room	HV-1	AHU	2,700 CFM 300 MBH
	EF-3	Exhaust Fan	4,650 CFM

Table 10-10 provides a summary of the basis of design performance criteria for HVAC systems at Leib and Table 10-11 provides the outdoor Basis of Design conditions.

Table 10-10. Leib Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (°F)	Summer (°F)	
Headworks	Class I, Group D, Div 1	N/A	N/A	12 ACH (Occupied)
Mechanical Spaces	Unclassified	60	96	Heat Relief
Office, Sampling Room, and Toilet Rooms	Unclassified	70	78 F Dry Bulb, 50% Relative Humidity	15 cfm per occupant

Table 10-11. Leib Original Outdoor Basis of Design Conditions

Outdoor Design Temperature		
Winter (Dry Bulb °F)	Summer (Dry Bulb °F)	Summer (Wet Bulb °F)
3	91	73

10.2.5.2 Identified Needs and Issues

During the CS-299 Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- Odor issue in Basin and Garage area. The louvered penthouses next to the stairwells had been seized closed and the supply air to the Headworks Area was not able to be relieved through the penthouses. This may have caused odorous air to be pushed out of the large blind flange for a potential future odor control system. It was noted after the meeting that the on-going CIP project HVAC Improvements, CIP 260611, GLWA Contract No. 1803718 will be restoring the louvers in the penthouses and installing new gasketing for the blind flange in the garage area. This should reduce odors in the garage.
- Access to SF-1 for maintenance and repair is difficult: There is very little clearance to service belts and bearings in the supply fan room.
- The Headworks is not provided with any heat: O&M staff noted that water has to be turned off after about November to prevent pipes from freezing and that humidity in the air can cause major condensation in the Headworks.
- Jacobs further evaluated this issue. The Headworks area was not originally designed to be a conditioned space. Adding heating/dehumidifying to prevent frozen pipes and condensation would be prohibitively expensive. Insulating and heat tracing pipes to prevent freezing was considered; however, heat tracing can fail without warning and then pipes could still freeze. Keeping a small flow of water through the pipes during the extreme winter cold periods could be explored. No capital costs have been applied to this issue.
- Improved cooling is needed in the control room. Jacobs further investigated this issue. GLWA's HVAC contractor noted that there have been major control issues at the facility in the past and control installations are taking place presently which should help improve operator comfort. It is recommended that the impact of the control changes on operator comfort be assessed after they are completed, and recommendations can be made for proposed changes if conditions do not improve. It should also be noted that the cooling equipment serving the office, sampling room, and toilet rooms was sized to provide a summer indoor temperature of 78°F. Because an operator routinely occupies the control room, consideration should be given to sizing the next AC unit for 72°F. No capital costs have been applied to this issue. The AC unit will be replaced.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- Dampers on HV-1 and HV-2 mixing boxes are not completely functional: GLWA's HVAC contractor noted although the actuators on the dampers are being replaced as part of an on-going project, the dampers may be in poor shape. Currently, they manually actuate the dampers.

During site investigations (June 2020) the following observations were noted:

- A roof has been constructed over both Entrance Courtyards: The as-built drawings show that these areas had no roof when they were originally constructed. Roofs have since been constructed over these areas with screens to keep out birds and insects. See discussion and photos below for further details.
- The on-going HVAC-related upgrade project (CIP No. 260611) will be upgrade the HVAC control system with DDC, replace dampers and actuators in the penthouse and within the indoor HVAC system, and replace the actuator and damper for the supply air to the basement.

10.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project LEIB-HVAC-1). Due to the relatively small nature of some of the HVAC related projects identified as improvements, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: HVAC Improvements** including,
 - Entrance courtyard modifications
 - Improved access to SF-1 for maintenance

Each of the HVAC related improvements listed above is described further below:

Entrance courtyard modifications. Another potential source of odors and a code compliance issue are the stairwells which are currently connected to the interior unclassified areas of the facility via the Entrance Courtyards on the East and West sides of the facility (Figure 10-2). The as-built drawings (Figure 10-3) show these areas as having no roof. This design does not constitute an enclosed space under NFPA 820 because it is open to the atmosphere. The building has been modified since construction to include a roof over both Entrance Courtyards and has been enclosed with bird screen between the existing wall and newly constructed roof.

Figure 10-2. Existing West (left) and East (right) Entrance Courtyard

Figure 10-3. As-Built Entrance Courtyard Design – Section through Building

NFPA 820 defines a space with a roof as “Not Enclosed” if 50 percent of its wall area is open to the atmosphere. This is clearly no longer the case with either of the Entrance Courtyards (Figure 10-4).

Due to their connection to the Headworks Area, the stairwells are technically Class I, Division 1 spaces per NFPA 820. The fact that they are connected to other areas of the facility via man doors, through the now enclosed Entrance Courtyards, effectively classifies the rest of the facility as Class I, Division 1. Although the Entrance Courtyards have combustible gas detection and some relief to the atmosphere, current versions of NPA 820 make it clear that such connections between unclassified and classified areas are only allowed via a pressurized airlock, with combustible gas detection monitoring and alarm, positive pressurization monitoring and alarm, and alarm if the airlock door is open for more than 20 seconds. This is not a feasible solution for the West Entrance Courtyard due to the intake for the Emergency Generator room in this area, but may be feasible for the East Entrance.

Figure 10-4. Entrance Courtyards – Plan view

To comply with NFPA 820 and ensure that hazardous gasses cannot enter the facility through the Entrance Courtyards in the future, Entrance Courtyard roofs should be removed.

Improved access to SF-1 for maintenance. SF-1 supplies ventilation air to the Headworks area and therefore the supply fan room is also a Class I, Division 1 area. Creating openings in either the generator room or garage area to improve access were considered; however, these would violate the physical separation between the classified supply fan room and unclassified generator room and garage area. One option would be to demolish the east wall of the supply fan room and move it further east with man door access added in the north wall, if necessary. See Figure 10-5 below.

Figure 10-5. Supply Fan Room – Plan view

The alternative evaluation is presented in Table 10-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- Although the access to maintain SF-1 would be improved by moving the wall, it is difficult to monetize this benefit. As such, there is no measurable difference in O&M costs between the two alternatives.

Alternative 2 is recommended based on the need for code compliance. This project should be conducted when a major upgrade is performed at the facility.

Table 10-12. Alternative Evaluation for HVAC Improvements (Project LEIB-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

10.2.6 Electrical

10.2.6.1 Description of Existing System

The Leib facility's electrical system consists of one DTE utility feed from a 480 V, 3-phase outdoor transformer (secondary metering) and one diesel generator feed from a 350 kW, 480 V, 3-phase stationary generator. The utility feed is connected to a 600 A motor control center (MCC-B) with a 600 A sub-feed connection to a 600 A ATS. The ATS then feeds a distribution panel with two 600 A breakers, which feeds two MCCs (MCC-A and MCC-C). The MCCs feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 10-13 provides a summary of the major electrical equipment for this facility.

Table 10-13. Major Electrical Equipment at Leib

Location	Major Electrical Equipment	Description
Generator Room	Generator (Diesel)	350 kW, 480/277 V, 3-Phase
Electrical Room	MCC-A	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-B	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-C	600 A, 480/277 V, 3-Phase

10.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The operators need to call an electrician to reset the mixer units, which is time consuming.

10.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project LEIB-ELEC-1). The operators need to call an electrician to reset the mixer units, which is time consuming. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Continue calling the electrician to reset the mixer units.
- 2) **Alternative 2: Electrical Improvements.** Add Reset Buttons to the outside of the MCC buckets for each chemical induction mixer motor. See Figure LEIB-ELEC-1-ALT-2 in Volume 6 – Appendices, Appendix C for location. The reset buttons will enable Operations to reset the mixers themselves when a trip occurs instead of contacting electricians to reset the mixer unit.

The alternative evaluation is presented in Table 10-14. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is only \$6,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.**

Table 10-14. Alternative Evaluation for Electrical Improvements (Project LEIB-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Do Nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	The operators need to call electricians to reset the mixer units, which usually takes a long time.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	3	3.43	\$ 19,000	\$ -	\$ 19,000	\$ 5,534	Not Applicable
	<i>Definition:</i>	Add reset buttons to the outside of the MCC buckets for each chemical induction mixer motor	Water Quality & Compliance	3						
	<i>Adv.:</i>	The operators do not need to call electricians to reset the mixer units	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

10.2.7 I&C

10.2.7.1 Description of Existing System

Control System: The original control system was installed in 2002 under PC-732. In 2004 the system was upgraded and interfaced into GLWA's overall SCADA Ovation control system. This upgrade provided the ability to remotely monitor the operations of the facility and the local collection system at SCC.

The existing control system contains an Allen Bradley-based PLC system consisting of an Allen-Bradley redundant PLC-5 with local I/O controls that are installed in the facility's local control system panel. The operator workstation software has a Rockwell RSVIEW operating platform and is located in the control room. The existing hardwired local back-up control panel and other miscellaneous subsystems that are incorporated into the overall control system are outdated and need replacement. The control system network and switches are obsolete and do not meet GLWA SCADA Governance standards on redundant networks and switches, and that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a back-up radio system to communicate critical monitoring points back to GLWA System Control on wide area network failure.

Flow and Level Sensors: Table 10-15 summarizes the level sensors and flow meters at the Leib CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 10-15. Summary of Flow Meters and Level Sensors at Leib CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent Sewer (Larger Sewer)	1	Transit-Time (AccuSonic)
Influent Sewer (Smaller Sewer)	1	Transit-Time (AccuSonic)
Towards Treatment Sewer	1	Transit-Time (AccuSonic)
Outfall	1	Transit-Time (AccuSonic)
CSO Facility Level Sensors		
Influent (Sewer and channel)	2	Ultrasonic
Mixing Chamber	1	Ultrasonic
Dewatering (Pumping station and control gate)	2	Ultrasonic
Effluent (Outfall, Towards Treatment Sewer)	2	Ultrasonic
DRI Discharge Regulator Chamber	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed Pumps	8	Magnetic

10.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Install an Outfall OIT

- Evaluate repair or replacement of the DRI level sensor
- Need for remote control of the regulator gates
- Ensure influent flow meter is properly positioned with new Meldrum connection
- Need for process cameras at select locations
- Evaluate influent flow meter will be properly positioned with new Meldrum connection. Based on GLWA's WWMP, a new diversion sewer is proposed to connect the Meldrum Sewer to the Conant-Mt. Elliot Sewer, which will divert flow from Meldrum to the Leib CSO Facility during wet weather events. GLWA staff expressed concern that the proposed location of the new junction chamber may impact the accuracy of the existing multi-path flow meter. The approximate location of the existing flow meter, as well as the proposed location of the new diversion sewer was shown previously in Figure 10-1.

The existing meter will likely be in a zone of higher turbulence near the new sewer connection, which will result in less accurate flow measurement. It is recommended that the flow meter be about 10 pipe diameters, or 160 ft, from the proposed junction chamber to ensure that the meter functions reliably. The proposed junction chamber is approximately 240 ft upstream of the existing influent diversion chamber to the CSO facility. As such, there is sufficient pipe length to relocate the meter downstream. In discussions with GLWA, Jacobs recognizes that the flow meter will be replaced in the near future. It would be most efficient to relocate the meter to a point that would account for the future diversion flow. Because a new influent flow meter is going to be installed at this location, costs are not provided in this report for relocation to address this issue.

- Need to replace the regulator gate limit switches. Replacement of the switches will likely require dewatering and flow diversion in the regulator structure, which could be a significant effort and cost. As such, this work should be considered for combination with other upcoming work at or near this location.
- The control system should be upgraded. GLWA is currently developing an FP) for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities." The project will replace the existing PLC-5 control system and back-up local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an on-going project that has already been included in the CIP.
- The screen graphics are very difficult to understand and should be updated to match other facilities. This improvement is included in the Control System Improvements project described in the previous bullet.
- Evaluate regulator gate limit switches. Remote control of the regulator gates is included under the "Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities" project. No further improvements are recommended.

10.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project LEIB-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation Control System Upgrade and the Automatic Transfer Switch and Generator Controls Upgrade, are

proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: I&C Improvements** including,

- Install an Outfall Operator Interface Terminal (OIT)
- Evaluate DRI level sensor
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Install an Outfall Operator Interface Terminal (OIT). In order to assist operations during CSO events, Operators requested an OIT at the Outfall. The OIT should be consistent with other OIT panels being installed throughout other CSO Facilities under the I&C Systems Project.

Evaluate DRI level sensor. It is recommended to replace the DRI level sensor.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 10-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – I&C Improvements has a total benefit score about 0.9 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and O&M. The NPV/Benefit cost for Alternative 2 is \$49,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 10-16. Alternative Evaluation for I&C Improvements (Project LEIB-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.53	\$ 109,000	\$ 3,000	\$ 172,269	\$ 48,755	Not Applicable
	<i>Definition:</i>	Install higher performance I&C instruments including Outfall OIT, level sensor, regulator gate limit switches, and process cameras. Project may be able to be split into multiple delivery projects if needed.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	5						

Control System Upgrade. The following control system improvements are recommended:

- Update Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

GLWA is currently developing an RFP for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Leib CSO Facility under *"Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities"*. The project will replace the existing PLC-5 control system and back-up local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace most of the field instruments.

The alternative evaluation table is not provided because this is an on-going project that has already been included in the CIP.

10.2.8 Site

10.2.8.1 Description of Existing Site

The Leib CSO facility was built in 2002. The site includes a 6-ft high security fence along the perimeter of the site. A sliding cantilever entrance gate is provided at the Mt. Elliott entrance. The parking lot consists of 8-in thick reinforced pavement with 8-in. crushed limestone base. There is a 5-ft wide, 4-in. thick sidewalk along the building entrances and 10-in. aggregate site pavement along the perimeter of the facility. Site utilities include potable water, natural gas, electrical, telephone services, stormwater, and sanitary sewer connections.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

10.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- There are safety concerns for those accessing the Leib CSO facility through the sliding cantilever entrance gate off of Mt. Elliot St.
- Need for additional space to store outside summer/winter site maintenance equipment. Jacobs evaluated this issue. All the equipment required for outside summer/winter site maintenance is stored inside the Leib facility in the space originally planned for the odor control room outside the control room. GLWA has requested additional space to store this extraneous equipment outside of the building. There is limited space for a permanent structure on the site without locating it over the treatment basin or influent/effluent conduits. One available location is at the south side of the property where there is an approximately 15-ft wide strip inside the fence line. The available area will depend on the required size of the storage building. While there is limited space on the current facility site to construct a permanent storage structure, it may be possible to locate a new storage building if

property is acquired for the new access drive entrance and the security fence and new gate alignment can be realigned to accommodate a secure area for a new storage building.

- Based on our understanding of the equipment to be stored, it appears that a small commercial secure garden shed style structure would be adequate; however, a more secure option would be to continue to utilize the existing space inside the Leib facility and plan for a storage facility outside as a new larger space may become available. As such, no capital costs have been provided for this issue.
- The Leib facility influent and effluent diversion junction chambers are located in Mt Elliott St. outside the facility boundary extending across two lanes of north bound traffic (approximately 20 ft in width). The diversion chambers were constructed on piles. The concrete junction chambers extend to the surface in Mt. Elliott St. Settlement of the asphalt-surfaced road has occurred around these structures. The settlement issue is more pronounced at the effluent diversion structure. We recommend that the roadway around the structures be reconstructed with a modified engineered fill that can help stabilize the roadway surface around the structures. As Mt. Elliott is a city-owned road, road reconstruction should be performed by the City of Detroit. However, a line item is included in the New Access from Meldrum Street project to address this issue.

GLWA is currently addressing some of the site needs at the facility. These on-going projects are described below and are not included in the capital improvement projects for CS-299:

- There are significant water infiltration issues at the Leib Outfall Sampling Vault near the Detroit River. The Sampling Vault shares a common wall with the east barrel of the outfall. A number of conduits carrying power and control wiring and cables penetrate the common wall near the base of the vault that corresponds with the elevation of the base of the outfall. The existing conduits service dewatering and sampling pumps, level sensors, proximity switches on backwater gates and a multi-path transit time flowmeter located upstream of the Sampling Vault. When wet weather events occur, infiltration into the conduits flows back into the Sampling Vault, flooding the base of a floor mounted control panel.

To prevent the backflow of treated water into the Sampling Vault, it is recommended to realign the penetrations of the existing conduits to an elevation above the waterline in the outfall conduits. The existing conduit penetration should be demolished, removed and the openings grouted shut. There are six 1.25- in. conduit penetrations and two 2-in. conduit penetrations that would have to be relocated. This is an on-going project and will be completed through a JOC.

- The following issues were addressed under GLWA-CON-1902040 "Site Improvements at P-F Detention Facility and Leib Screening and Disinfection Facility" Contract.
 - Address Facility Drainage. The surface of grade over the treatment facility is very flat and as a result water ponded on it.
 - Repair Concrete Sidewalk. The 4-ft wide access sidewalk around the perimeter of the Leib CSO facility has been impacted by settlement issues that have caused the sidewalk to pull away from the building and crack.
 - Caulk joints at expansion joint between base of wall/sidewall – all sides of building.
 - Seal all control joints and cracks in the concrete parking lot pavement.
 - Repair collapsing catch basin.

10.2.8.3 Description and Evaluation of Alternatives

A project to address the need identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

New Site Access from Meldrum Street (Project LEIB-SITE-1). The existing site access through the sliding cantilever entrance gate off of Mt. Elliott St. creates safety concerns for those accessing the Leib CSO facility site. The existing site fence line and security gate on the west side of the facility is located immediately behind the street sidewalk. As a consequence, there is not enough space for vehicles to completely pull forward onto the drive approach to the site without the vehicle remaining partially in the lane of traffic on Mt. Elliott. As a result, some drivers exit their vehicles while in traffic to swipe security access cards to open the gate. Furthermore, some drivers park their vehicle in the turn lane and cross the traffic to open the gate. This poses a slip and fall safety concern, especially in the winter in inclement weather. Several alternatives have been investigated to address this issue, including realigning the fence and gate location off Mt. Elliott so that vehicles can pull fully out of the traffic lane to access the card reader and wait for the gate to open. This alternative, however, does not appear to be practical due to the significant encroachment on the existing parking lot necessary to create space for cars and trucks to pull off Mt. Elliott Street. In addition, realigning the gate would not allow proper maneuverability for vehicles in the parking lot.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: New Site Access from Meldrum Street.** This alternative includes relocating the site entrance to the east side of the site off Meldrum Street. See Figure LEIB-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the conceptual layout. There are several parcels of vacant property immediately adjacent to the east side of the Leib facility. Three of these parcels align with the existing Leib parking lot on the north side of the facility. An access road could be constructed off Meldrum to allow an alternative entrance to the Leib facility. This alternative would include construction of a new 24-ft wide access driveway. The length of the drive would be approximately 175-ft off Meldrum. The facility's existing east fence line would be modified to accommodate a new sliding cantilever gate and access card reader. The Detroit GIS parcel database indicates the vacant properties on the east side of the site are owned by the Detroit Water and Sewerage Department.

This alternative includes the paving of Mt. Elliot in front of the Leib facility.

The alternative evaluation is presented in Table 10-17. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.15 higher than the Do Nothing Alternative (Alternative 1) based on the improved safety and component performance. The NPV/Benefit cost for Alternative 2 is \$65,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 - New Site Access from Meldrum Street, is the recommended alternative.**

Table 10-17. Alternative Evaluation for Site Access (Project LEIB-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety concerns remain	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	New Site Access from Meldrum Street	Health and Safety	4	3.38	\$ 220,000	\$ -	\$ 220,000	\$ 65,025	Not Applicable
	<i>Definition:</i>	Relocate the site entrance to the east side of the site off Meldrum St.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Increased safety for personnel accessing the facility.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.9 Architectural

10.2.9.1 Description of Existing Facilities

The Leib CSO facility consists of chemical room, utility support (electrical, emergency generator and mechanical), control room, odor control room, screen room, sampler room and other miscellaneous rooms. The facility also includes an underground influent channel.

10.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated the leak from the chemical storage tank damaged the floor coating in the chemical room. The recoating of the floor is included in LEIB-DIS-1 project.

10.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (LEIB-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints
- Remove and replace isolation/ cove joint sealant and around building perimeter
- Clean and coat bottom of all door frames
- Clean corrosion and coat underside of roof deck

- Clean and coat localized areas of roof beams and framing members
- Remove debonding roof deck paint, clean and replace with new paint
- Replace cracked limestone windowsill and caulk on the southeast side of the building

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings (Figure LEIB-ARCH-1-ALT-2) in Volume 6 – Appendices, Appendix B. Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project. It should be noted that recoating of the floor in the Chemical Room was originally included in the architectural items, but moved to the Chemical Feed project (LEIB-DIS-1).

The alternative evaluation is presented in Table 10-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 10-18. Alternative Evaluation for Architectural Rehabilitation (Project LEIB-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 246,000	\$ -	\$ 246,000	\$ 79,355	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.10 Safety

10.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

10.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 10-19. The capital improvement project to address these issues is included in the table.

During the Needs Assessment meeting for Disinfection, O&M staff noted the tanks lack fall protection to allow safe access to appurtenances and valves above the tank. Fall protection is desired for safety.

It is recommended that either the handrail style fall protection, similar to Belle Isle and Oakwood, or the solid style fall protection similar to Hubbell-Southfield be added to the top of the two hypochlorite tanks. This will require a technician skilled in working with FRP to bond the fall protection to the tank. FRP tank manufacturers offering field repair services would be able to do this work.

Table 10-19. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Garage	No exit sign	Add exit sign	Exit Sign Improvements ^a
Chemical Room	No guardrails on tanks	Add guardrails	Safety Improvements (Project LEIB-SAFE-1)
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project LEIB-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

10.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project LEIB-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend guardrails on tanks in the chemical room to eliminate fall hazard
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 10-20 shows the one alternative.

Table 10-20. Alternative Evaluation for Safety Improvements (Project LEIB-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 211,000	\$ -	\$ 211,000	\$ 70,333	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

10.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Leib CSO Facility.

10.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Leib CSO facility, Table 10-21 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 10-21, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 10-21. Listing of Asset Condition Assessments for Leib Facility

^a The fire suppression was evaluated Simplex Grinnell in 2018 and not included in the ACES report. ^b The gas detector is a portable unit and was not assessed. ^c The one pump not evaluated was a sample pump originally in the in the disinfection channel, which is no longer used.				

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Leib Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

10.3 Capital Planning for Leib CSO Facility

10.3.1 Summary of Capital Improvement Plan Projects

Table 10-22 provides a summary of the recommended CIP projects and associated capital costs for the Leib CSO facility based on the alternative evaluations conducted for this facility .

Table 10-22. Summary of Recommended Projects at Leib CSO Facility

Project No.	Alternative	Description	Total Project Cost
LEIB-DIS-1	3	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 901,000
LEIB-DIS-2	2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
LEIB-DIS-3	2	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
LEIB-FD-1	2	Screening Chamber Flushing System	\$ 16,000
LEIB-HVAC-1	2	HVAC Improvements	\$ 126,000
LEIB-ELEC-1	2	Electrical Improvements	\$ 19,000
LEIB-I&C-1	2	I&C Improvements	\$ 109,000
LEIB-I&C-2	1	Control System Upgrade	Ongoing Project
LEIB-SITE-1	2	New Site Access from Meldrum Street	\$ 220,000
LEIB-ARCH-1	2	Architectural Rehabilitation	\$ 246,000
LEIB-SAFE-1	1	Safety Improvements	\$ 211,000

10.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 10-23. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 10-23. Capital Improvement Plan Projects for Leib CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
LEIB-1 Disinfection System Improvements	\$ 1,206,000	2026 <i>Timing based on implementation of projects before Meldrum diversion to ensure reliable operation with increased flows.</i>	LEIB-DIS-1	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 901,000
			LEIB-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
			LEIB-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	\$ 50,000
			LEIB-FD-1	Screening Chamber Flushing System	\$ 16,000
			LEIB-ELEC-1	Electrical Improvements	\$ 19,000
LEIB-2 Facility-Wide Safety and Architectural Improvements	\$ 583,000	2023 <i>Project should be initiated as soon as possible</i>	LEIB-HVAC-1	HVAC Improvements	\$ 126,000
			LEIB-ARCH-1	Architectural Rehabilitation	\$ 246,000
			LEIB-SAFE-1	Safety Improvements	\$ 211,000
LEIB-3 I&C Improvements	\$ 109,000	2030 <i>Timing based on best judgement</i>	LEIB-I&C-1	I&C Improvements	\$ 109,000
LEIB-4 Site Improvements	\$ 220,000	2026 <i>Timing based on need to address safety issue</i>	LEIB-SITE-1	New Site Access from Meldrum Street	\$ 220,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 10-24 and Table 10-25 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 10-24 indicates that LEIB-DIS-1 project has 28 assets that has an average condition score of 1.29 and an average replacement date of 2032. However, this project should be completed before the Meldrum diversion and therefore, the project was proposed a scheduled construction completion date of 2026 instead of 2032.

Table 10-24. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
LEIB-DIS-1	28	1.36	1.29	2.27	13	2032	\$ 904,400

Table 10-25. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
LEIB-DIS-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

10.3.3 20-Year Capital Outlay Plan

Table 10-26 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 10-26. 20-Year Capital Outlay Plan for Leib CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 300,900	\$ -	\$ -	\$ 217,500	\$ 59,200	\$ -	\$ -	\$ 24,200	\$ -	\$ -	\$ -	\$ -	\$ -

2040	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
Total	\$ 10,135,347	\$ 165,999	\$ 1,845,614	\$ 2,630,160	\$ 1,608,094	\$ 129,231	\$ -	\$ 320,589	\$ 1,419,765	\$ 1,769,773	\$ 155,887	\$ 62,820	\$ 27,416

Notes:

Explanation of large capital outlays in first two years:

- Screening System: Screen #3, #5, and #7 received a score of 5 as the screens failed to start at the time of the Condition Assessment.
- Retention System: One Accusonic flow meter (FM-3; \$217,500) was not functional based on SCADA review in 2019 and 2020.
- Disinfection System: One chemical storage tank #2 (\$59,200 each) received a score of 5 as it had a small leak and had been taken out of service until repaired.

11. Oakwood CSO Control Facility

11.1 General Facility Description and Future Capacity Considerations

11.1.1 General Facility Description

The Oakwood CSO Facility is an RTB with 9 million gallons (MG) of storage and a treatment capacity of 1,660 cfs. It was constructed in 2012. There are three buildings. The main building contains the Storm Pump Station, Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, MAU room and hydraulic room. The basin odor control room contains the odor control systems for the East and West Basins.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

11.1.2 Northwest Interceptor Diversion to Oakwood CSO Facility

The WWMP proposed projects to increase wet weather flows to existing CSO facilities to maximize the use of the facilities and minimize the construction of additional facilities. Many of the CSO facilities do not reach their design flows, so there is capacity to accept additional flows, without exceeding their design flow.

The NWI Diversion to Oakwood CSO Facility is one of the recommended projects from the WWMP that will increase flows to the existing Oakwood CSO Facility. The magnitude of the increased flows and the potential impact on screening and disinfection performance is described in the following sections.

This project originated from the WWMP and involves diverting NWI flows to the Oakwood Storm Pump Station and CSO facility whenever the Detroit WRRF is overloaded, and capacity is available at the Oakwood facility. Based on information presented in the WWMP, the predicted peak wet weather flow rate expected at the Oakwood Pumping Station (PS) for the 10-year 24-hour storm event is about 1,100 cfs. The firm capacity of the Oakwood PS and the design flow for the CSO facility is 1,660 cfs. This leaves about 560 cfs of unused capacity at the Oakwood facility at design conditions.

The NWI diversion involves construction of a new control gate chamber on the NWI at Bayside and Sanders. About 3,100 ft of 10-ft-diameter tunnel is required to convey the peak wet weather flows from the NWI control gate chamber to a new diversion chamber at Liddesdale and Pleasant Streets, near the Oakwood influent junction chamber.

11.2 Facility Assessment

11.2.1 Screening

11.2.1.1 Description of Existing System

The Oakwood CSO Facility has six perforated plate screens that were installed in 2012. Raw wastewater is pumped to the screens from the Oakwood Storm Pump Station. Screened flow enters either one or both of the CSO basins via the Screen Outlet Chamber.

Screened material is removed from the screens using a rotating brush and high-pressure spray and discharged into a screw conveyor. The conveyor transports the screenings to a dumpster for eventual disposal in a landfill. A washer/compactor was originally installed at the end of the conveyor, prior to discharge to the dumpster.

The sanitary pump station has two manually cleaned bar screens upstream of the sanitary pumps. Space was provided in the Sanitary Pump Station for a monorail system and bucket that could be used to manually clean the screens if it were determined necessary in the future.

Table 11-1 provides an overview of the existing screening system at Oakwood CSO facility.

Table 11-1. Overview of Existing Screening System Oakwood CSO Facility

Parameter	Value	
Type	Retention Treatment Basin	Sanitary PS
Treatment Capacity (cfs)	1,660	NA
No. of Screens	6	2
Manufacturer	Andritz	Not known
Screen Type	Perforated Panel Screen	Manual Bar Rack
Opening Size	6-mm perforation	3-in.
Depth or Length	21 ft 6 in.	41 ft
Width	10 ft 0 in.	5 ft 0 in.
Screen Cleaning	Brush and high-pressure spray	Manual
Screening Removal	Screw conveyor to dumpster and landfilled	Manually cleaned (currently by washing screenings through the screens to the sanitary pumps)

11.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide a better means of cleaning the two bar racks at the sanitary pump station: The bar racks have 3-in. spacing to protect the sanitary pumps by capturing large debris. The sanitary pump station bar racks, however, become frequently blinded. During Jacobs Condition Assessment in June 2020, the differential through the screens was about 10 ft. The screens reportedly had not been cleaned for a prolonged period due to accessibility issues. The current method of cleaning involves lowering a worker in a man-basket into the wet well to manually remove the debris, which poses considerable safety risks. Alternatives to address this issue are discussed in the following section.
- Resolve water carry-over into screenings dumpster and onto floor near dumpster: Screenings and spray water from the screens are conveyed by the screw conveyor directly into the dumpster at ground floor. There is a significant amount of water that completely fills the dumpster during an event and spills onto the floor around the dumpster. A portable screenings washer/compactor was provided in the original system and can be moved into place to wash and compact the screenings. The washer/compactor has a drain that can divert the excess water to a drain line. The compactor, however, has been problematic because screenings fill the compactor chute, dry in place, and are unable to be pushed out of the chute during the subsequent storm. As such, the washer/compactor is bypassed.

- Jacobs recommends replacing the inclined discharge chute with a minimally modified chute. This will minimize compaction of the screenings and, most importantly, will allow the excess water to drain from the screenings prior to discharge into the dumpster below. This should significantly reduce the amount of water transferred to the dumpster. Jacobs contacted the washer/compactor manufacturer (JWC) to confirm this approach. The GLWA millwrights could construct and install a new horizontal section. The capital expenditure for this modification is minimal and not included in the capital outlay.
- Potential impact of higher flows on screening performance. The screens have not experienced peak design flows, and there is a concern that they may blind at the higher flows with the NWI diversion. It should be noted that the screens have emergency bypasses built-in to the screening channels to allow flows around the screens if the screens should become blinded. If screen blinding should become a problem in the future, potential modifications to the existing screens, including speeding up the screen, could be investigated. There is no room for additional screens at the facility.

11.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Sanitary Pump Station Screen Improvements (Project OKW-SCR-1). The existing manually raked bar screens excessively blind over time and cleaning them is a safety concern. There are four alternatives:

- 1) **Alternative 1: Do Nothing/Keep Existing Manual Bar Rack**
- 2) **Alternative 2: Remove Bar Racks.** The bar racks were installed to protect the sanitary pumps. Due to the excessive blinding of the bar racks, GLWA recently temporarily removed the bar racks. This will allow observation of pump performance without screening. If the pumps can convey most of the debris, this could be the long-term alternative. GLWA should observe this performance for at least a year to determine the impacts on the pumps and the material that remains in the wet well.
- 3) **Alternative 3: Monorail and Clamshell.** The facility was originally designed for a monorail and clamshell to remove the screenings from the manual bar racks, but it was not installed. A clamshell could be used to clean bar racks with 3-in. openings as the captured debris is usually large/heavy. A clamshell would be faster and safer to use than the man-basket that was previously used. However, GLWA subsequently requested a mechanical bar screen in lieu of continuing to use the manual bar racks based on operational experience with clamshells being unreliable.
- 4) **Alternative 4: Mechanical Bar Screen.** The bar racks could be replaced with mechanical bar screens with the same 3-in. bar spacing that extend the full depth of the channel. Duperon's FlexRake FP-F bar screen was evaluated and would perform well (see Figure OKW-SCR-1-ALT-4 in Volume 6 – Appendices, Appendix B). It was used as a representative screen for cost estimating purposes. A smaller bar spacing of 1.5-in. is an option but will result in additional screenings to manage. The spacing of a new screen, if this option is selected, should be further evaluated during detailed design.

Several options for screenings handling were evaluated for the mechanical screens in Alternative 4:

- **Screenings Handling Option 1: Rolling Dumpster:** A rolling dumpster with a drain should be adequate for screenings from a 3-in. bar screen. The portable dumpster could be moved just outside the roll-up door and picked up by a trash truck. Screenings captured with a 3-in. bar screen are not expected to be odorous.
- **Screenings Handling Option 2: Grinder After Mechanical Screen:** Rather than disposing of screenings at the Oakwood facility, screenings could be ground and returned to the screened wastewater and conveyed to the WRRF. Screens at the Detroit WWTP would remove the ground screenings. The grinder teeth can be set to grind the screenings to the desired size, so they are mostly removed by the treatment plant screens. Conversations with a Jacobs' screening expert

and Duperon indicated that maintenance on the grinder will be intensive due to the large material that will be ground. The likelihood and frequency of jammed grinders is high, and a rolling dumpster is a better disposal option.

- Based on the evaluation above, a rolling dumpster (Screenings Handling Option 1) is recommended as a grinder has a higher potential for future maintenance problems than its apparent overall value.

The alternative evaluation is presented in Table 11-2. The sources of costs used in this evaluation are listed the following bullets:

- O&M costs for Alternative 1 assume the manual bar rack is cleaned twice per year.
- Alternative 3 – Monorail and Clamshell is not considered a viable alternative by GLWA because of unfavorable experiences with this type of system at other facilities.
- Capital costs for Alternative 4 are presented in Volume 6 – Appendices, Appendix C under this project title.
- Screenings disposal costs are not included in Alternative 4 because the cost difference is so large between Alternative 2 and Alternative 4.

This evaluation shows that Alternative 2 – Remove Bar Racks is the Best Value Alternative. **As such, Alternative 2 is the Recommended Alternative.**

Table 11-2. Alternative Evaluation for Sanitary Pump Station Screen Improvements (Project OKW-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	Disadv.:	Higher capital cost. Need for screenings disposal.	Component Performance	5						
	Comments:	Does not include screenings handling	O&M Ease	5						

11.2.2 Disinfection

11.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, 10 gear pumps, and multiport injection on the discharge of the eight stormwater vertical turbine pumps. The storm pumps pump stormwater into the CSO facility and are further described in Section 11.2.12.1. Three of the sodium hypochlorite pumps are low-rate and seven are high-rate. Sodium Hypochlorite Pumps 1 through 8 inject on the discharge of Storm Pumps 1 through 8, respectively. Sodium Hypochlorite Pump 9 is a high-rate pump serving as the backup to high-rate pumps 3 through 8. Sodium Hypochlorite Pump 10 is a low-rate pump serving as the backup to low-rate pumps 1 and 2. Each pump has a VFD to adjust chemical feed flow based on storm pumping rate. Flow is metered from each pump.

Table 11-3 provides an overview of the existing disinfection system at the Oakwood CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 11-3. Overview of Existing Disinfection System at Oakwood CSO Facility

Parameter	Value
Treatment Capacity (cfs)	1,660
Design Feed Strength (% hypochlorite)	7.5
Max. Dosage at Design Flow (mg/L Cl ₂)	12
Disinfection Contact Time (min)	6 min w/ 1 basin, 12 min w/ 2 basins in service
Storage Tanks	
Number	2
Volume of Each Tank (gal)	11,500
Type	FRP
Pumps	
Number	10 Total; 3 low-rate, 7 high-rate

Type	Gear
Mixers	
Number / Type	Hypo added to pump discharge
Model Number/ hp / Manufacturer	Not Applicable (Hypo added to pump discharge)

11.2.2.2 Identified Needs and Issues

The needs and issues for Oakwood were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are summarized as follows:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Oakwood chemical feed system has the following issue:
 - The gear pumps are expensive to replace and repair
 - The gear pumps vibrate despite efforts to eliminate vibration
 - The chemical feed pumps are on skids. The skid frames reduce access to the pumps and components and do not aid in the removal of the pumps.

These issues are addressed in Replace Chemical Feed System (Project OKW-DIS-1) in the following bullets.

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2) in the following bullet.
- Provide ability to sample basin at two levels. The basin effluent sample pump requires the water level to reach a certain level before chlorine residual can be determined. There is concern that it could be too late to adjust the sodium hypochlorite feed rate in response to variable influent conditions affecting chlorine demand by not being able to sample sooner. Therefore, it is desired to sample at two levels, one at low level in addition to the high level at end of basin. It should be noted that this capability will be provided in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2) by installing a new pump well upstream of the effluent end of the CSO basins. As such, a separate capital improvement is not needed to address this issue.
- Feed piping overpressure alarms. There is a pressure sensor and associated alarm setpoint on the discharge of each pump. Over-pressurization alarms occur indicating the need to investigate whether the pressure relief valves are functioning properly or whether the pressure sensor is causing false alarms.

This should not be an issue after the chemical feed system is replaced, as recommended in the following bullet. In the interim, however, the pressure relief valves could be investigated to verify they are functioning properly and that the pressure sensors be checked to determine if they are causing false alarms. This can be done by installing a calibrated pressure gauge on the discharge of a pump and monitoring pressure concurrently with someone monitoring SCADA for an alarm. GLWA maintenance staff could perform this investigation or a mechanical contractor. Given that the system should be replaced in the near future, capital costs have not been included in this evaluation to address this issue.

- Investigate corrosion concern at chemical injection points on pump discharge. During meetings related to disinfection, GLWA expressed concern that corrosion could be occurring in the vicinity of where the hypochlorite is injected into the discharge pipes of each pump. Closed-circuit television (CCTV) results of the discharge pipes for each pump (conducted under another project) were reviewed for this evaluation. See Figure 11-1 for CCTV results from the chemical injection points of one pump (Pump 2) used to illustrate the condition. The CCTV did not show any serious corrosion. Based on these results, it is recommended to re-investigate the piping again in about 5 years.

Figure 11-1. CCTV Inspection of Oakwood Storm Pump Discharge Piping Showing Chemical Injection Points

- Provide side access manway on hypochlorite tanks for improved ease of inspection and future relining.
- Provide backup storm pump flow measurement, for when the storm pump flow meter is not working properly—this issue is addressed in the Oakwood I&C section (Section 11.2.7).

11.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project OKW-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to each discharge point (i.e., pump discharge pipe).
- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 11-4. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.

- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on average annual costs of \$66,000 for manufacturer rebuilds and \$57,000 for GLWA on-site rebuilds (includes GLWA labor) for a total of \$123,000.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on rebuild of \$20,000 per pump for three pumps at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 11-4 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Table 11-4. Alternative Evaluation for Replace Chemical Feed System (Project OKW-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System In-Kind	Health and Safety	3	2.08	\$ 1,964,300	\$ 123,000	\$ 4,558,325	\$ 2,187,996	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2

	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose using an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The storm pump flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on storm pump flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows. The sampling location would be near the influent end of the basin and near the bottom portion of the basin (to be able to measure TRC concentrations before the effluent sample point). Another sampling point can be provided at an intermediate level.

The automatic chemical feed system should require less operator input during an event; however, this cost difference is not included in this analysis because GLWA O&M staff believe that manual sampling to confirm the auto sample result will still be necessary. There will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 11-5. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.
- As noted above, this evaluation did not account for any reduction in operations labor using the automatic control system.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Table 11-5. Alternative Evaluation for Provide Flow-paced and TRC-paced Automated Chemical Feed (Project OKW-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Continue Manual Adjustment of Chemical Feed	Health and Safety	3	2.40	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less efficient chemical feed and possible overdosing of chemical.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 156,000	\$ 4,860	\$ 258,496	\$ 74,926	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing. Also, provide sampling at two levels, one at low level and one at an intermediate level, in addition to the high level at end of basin.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more efficient use of chemical.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common of CSO facilities, but TRC-pacing is difficult with infrequent CSO facility use.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

Reline and Provide Side Access Manway on Hypochlorite Tanks (OKW-DIS-3). The hypochlorite storage tanks lack side entry manways making FRP repair significantly more difficult. A side entryway manhole near the bottom of each existing tank is recommended. This should be performed when the tank requires relining or a major repair. To determine the condition of the tanks, Jacobs reviewed a 2020 inspection by GHD and found that there was a only a small chip on the exterior of one tank and evidence of leakage from a drain valve (exterior to the FRP tank and not part of the tank).

Based on the limited extent of any defects to the existing tanks, it is recommended that the installation of the manways be done when the tanks near the end of their useful life and require relining. The costs for relining and adding manways to the existing tanks are included in the capital costs for this project. There is no alternative to this option. Table 11-6 provides the summary of **Reline and Provide Side Access Manway, which is the recommended alternative.**

Table 11-6. Alternative Evaluation for Reline and Provide Side Access Manway on Hypochlorite Tanks (OKW-DIS-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Reline and Provide Side Access Manways	Health and Safety	3	3.00	\$ 289,000	\$ -	\$ 289,000	\$ 96,333	Best Value Alternative
	<i>Definition:</i>	Reline and Provide Side Access Manways on Hypochlorite Tanks	Water Quality & Compliance	3						
	<i>Adv.:</i>	Re-use existing chemical tanks	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.3 Odor Control

11.2.3.1 Description of Existing System

There are three odor control systems at the Oakwood facility. One system, located in the Odor Control Building next to the sanitary pump station, treats air from the east and west storm wet wells, the sanitary wet wells, and the sanitary pump station room. The second and third systems, both located in the Basin Odor Control Building, treat air from the East and West Retention Basins. Each of the retention basin odor control systems also serves the headworks, as it is connected to both CSO basins.

The system serving the pump stations consists of a grease filter/mist eliminator, an odor control fan, and a single bed vertical activated carbon vessel. The system also includes a bypass ventilation fan, which allows foul air to be removed from the pump stations and bypass the carbon column. Carbon is replaced through the top access hatch on each vessel.

The systems serving the retention basins operate in parallel. Each system consists of an odor control fan and an activated carbon vessel (there are no grease filter/mist eliminators). Each system also has a bypass ventilation fan.

These odor control systems operate under air permit requirements (Permit to Install No. 91-06). The emission limit for the Pump Station system is 0.0043 pounds per hour (pph) of hydrogen sulfide. At a design air flow of 30,000 cfm, this equates to approximately 0.028 parts per million volume (ppmv) concentration of hydrogen sulfide. The emission limit for the CSO basin systems is 0.0031 pph. At a design air flow rate of 22,000 cfm (each), this equates to approximately 0.028 ppmv concentration of hydrogen sulfide. The carbon is tested for remaining bed life on a quarterly basis as required by the permit. Carbon was replaced in all three carbon vessels in Spring 2018, which was the first time it was replaced since it was put into service in 2012.

Per GLWA, no odor complaints have been received for at least the past three years.

11.2.3.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified:

- Improve odor control for the sanitary pump station.
- Provide improved access and safety for carbon replacement for both the sanitary and basin scrubbers.
- Provide improved access and safety for carbon sampling for both the sanitary and basin scrubbers.
- West basin odor control fan was out of service due to vibration. Vibration monitoring was not installed properly resulting in frequent fan shutdown when vibration is not excessive.

These issues are discussed below.

Oakwood HVAC Improvements Project (CIP No. 260619). The Oakwood HVAC project, currently in the design stage, will include 1) improvements to odor control for the sanitary pump station; 2) improvements for access and safety for carbon replacement for both the sanitary and basin scrubbers; and 3) improvements for access and safety for carbon sampling for both the sanitary and basin scrubbers. Capital costs are not provided because this is an ongoing project.

Vibration Sensor Modifications. Install vibration monitoring closer to the frame of the fan. This will be done as part of the Oakwood HVAC Improvements (CIP No. 260619).

11.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement “needs”.

11.2.4 Flushing and Dewatering

11.2.4.1 Description of Existing System

Dewatering System: The Oakwood screening facility and CSO basins (East and West) are largely dewatered by gravity through drain lines that discharge to the NWI force main. The CSO drain system has sufficient capacity to allow both CSO basin drain valves to be opened simultaneously; however, there is a flow control valve and magnetic flow meter provided on the drain line to the NWI to control the flow to the NWI to prevent overflows in the collection system between the CSO Basin and the WRRF. Also, there is a Surge Chamber on the gravity drain lines that will direct flow back to the head of the plant if the basin dewatering flow rate exceeds the available capacity in the line to the NWI.

Due to system hydraulics, the water in the lowest levels of the basins that cannot be discharged to the NWI by gravity is instead routed back to the Oakwood Pump Station, where flow is pumped by the sanitary wastewater pumps to the NWI.

Flushing System: A flushing gate system is used for cleaning solids from the floor of the basin following dewatering. There are 20 total flushing gates—eight in each of the two CSO basins, and two in each of the two basin influent channels. The flushing gates in each basin are arranged in two groups of four. The flushing gates operate in a latch-unlatch manner and are controlled by a common hydraulic power pack.

The flushing reservoirs are filled as the basins fill during a wet weather event. When the basin and screening facilities dewater, flushing water remains behind the flushing gates. Flushing is initiated by sequentially unlatching two basin flushing gates (one in each basin) at a time in the first basin reservoir until all are open. Then, if the last of the four reservoirs was full prior to its gate opening, the second set of flushing gates will sequentially open. Once basin flushing is completed, one gate is opened in each influent channel. The flushing sequence only allows one gate in each channel to be open at a time.

Table 11-7 provides an overview of the existing flushing and dewatering system at Oakwood CSO facility.

Table 11-7. Overview of Existing Flushing and Dewatering System at Oakwood CSO Facility

Parameter	Value
Total Basin Volume (MG)	9
Headworks and Basin Dewatering and Flushing System	- Basins are dewatered by gravity by opening the Drain Valve to the NWI - There are 20 flushing gates; 8 in each basin and 2 in each basin distribution channel - Flushed solids are routed to the Oakwood Pump Station for pumping to the NWI

11.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed in the following bullets and further described in the next section.

- Air-operated pinch valve intended to isolate the two sides of the Storm Pump Station during dry weather are encased in sand, making them extremely difficult to access, and the air lines that actuate them are underground and have a leak, which cannot be found.
- Flushing valves are hard to reach during maintenance activities and scaffolding needs to be setup to reach the valves, which is difficult due to steep slope on the floor
- Significant grit accumulation at the flushing sumps in the basin leads to plugging of the 12-in. drainage pipeline at the effluent end of the basin

11.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Influent Junction Chamber Isolation (Project OKW-FD-1). The existing influent chamber has two 18-ft diameter sewers from the junction chamber to the Oakwood Storm Pump Station. Within the junction chamber, at the bottom of each 18-ft diameter pipe, there is a 30-in. diameter pipe with an air-operated pinch valve intended to isolate the two sides of the Storm Pump Station during dry weather. These pinch valves are encased in sand, making them extremely difficult to access, and the air lines that actuate them are underground and have a leak, which cannot be found. As such, they have not been repaired after they failed. A means to isolate the two sides of the Storm Pump Station is still needed. A previous study (Oakwood CSO Pump Station Investigative Study, Brown and Caldwell, January 15, 2019) identified several alternatives that included replacement of the existing pinch valves and new stop logs. Jacobs reviewed this study and discussed cost effective options with GLWA. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Contractor to install isolation, when needed.
- 2) **Alternative 2: Influent Junction Chamber Isolation Improvements.** This alternative includes removal/replacement of the existing dry weather flow pinch valves with new small hand-pull slide gates. Figure OKW-FD-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the conceptual layout of this improvement. Following removal of the pinch valves and demolition of the concrete boxes, brackets for a 36-in. by 36-in. hand-pull slide gate will be mounted on the rehabilitated concrete face of the 30-in. pipe in each channel. The hand-pull gates (two service and one spare) could be stored in the upper part of this structure. Flow bypassing is assumed during modifications.

This project should be coordinated with the NWI Diversion project to coordinate and minimize shutdowns and bypass pumping requirements.

The alternative evaluation for these alternatives is presented in Table 11-8. The sources of costs used in this evaluation are listed in the following bullets:

- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 includes the estimated cost of isolation, which is based on \$60,000 per event and frequency of use is assumed to be once every 5 years, for an annual O&M cost of \$12,000.
- The O&M costs for Alternative 2 includes the estimated cost of isolation, which is based on \$2,000 per event and frequency of use assumed to be once every 5 years, for an annual O&M of \$400.

The total benefit score for Alternative 2 is about 0.8 greater than Alternative 1. Also, the NPV/Benefit cost for Alternative 2 is less than Alternative 1. As such, **Alternative 2 - Influent Junction Chamber Isolation Improvements is the recommended alternative.**

Table 11-8. Alternative Evaluation for Influent Junction Chamber Isolation (Project OKW-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.58	\$ -	\$ 12,000	\$ 253,076	\$ 97,965	
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Unable to isolate the two sides of the Storm Pump Station during dry weather.	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Influent Junction Chamber Isolation Improvements	Health and Safety	3	3.42	\$ 289,000	\$ 400	\$ 297,436	\$ 87,054	Best Value Alternative
	<i>Definition:</i>	Removal/replacement of the existing dry weather flow pinch valves with new small hand-pull slide gates.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Simple system to isolate storm pump wet well.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Still requires manned entry into junction chamber, when needed	Component Performance	5						
	<i>Comments:</i>	None	O&M Ease	4						

Reservoir Flushing Valves and Basin Sump Flushing (Project OKW-FD-2). The O&M staff noted that the flushing valves are hard to reach during maintenance activities and scaffolding needs to be setup to reach the valves, which is difficult due to steep slope on the floor.

O&M staff also report that significant grit accumulation at the flushing sump leads to plugging of the 12-in. drainage pipe at the effluent end of the basin. Frequent jetting of this pipe is difficult due to the configuration of the pipes below the facility's slab and the depth to the flushing sump below the adjacent finger weir. There are also two 10-in. drain lines on the influent end that plug, but at a lesser frequency.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Continue to jet-rod the pipe, when necessary.
- 2) **Alternative 2: Reservoir Flushing Valves Relocation and Basin Sump Flushing.** This alternative relocates the reservoir flushing valves and piping to downstream of flushing gates, where the slope of the floor is less steep. Figure OKW-FD-2-ALT-2 in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

Improvements to mitigate the pipe clogging include installing submersible solids handling pumps (4-in. discharge) at each sump to recirculate effluent near the sump drains and resuspend accumulated materials. A 4-in. ductile iron discharge manifold mounted around the sump with two or three nozzles pointed toward the sump opening would support more complete resuspension while the basin is use. See Figure OKW-FD-2-ALT-2 in Volume 6 – Appendices, Appendix B for conceptual illustration. As the facility comes into operation, the pumps would start operating and continue operation for the duration of the event and as the facility is drained. By preventing a large accumulation at the sump, the draining process can more effectively dewater the facility and gradually remove settled materials. Pumps would be rail-mounted and removable to the surface through new hatched openings in the top of the structure.

The alternative evaluation for these alternatives is presented in Table 11-9. The sources of costs used in this evaluation are listed in the following bullets:

- The O&M cost for Alternative 1 includes the estimated cost of setting up scaffolding and jetrodding. The cost of scaffolding is based on \$15,000 per event and frequency of use to be once every 10 years. The cost of jetrodding is based on \$10,000 per event and frequency of use to be once every year.
- The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 2 includes the estimated cost of setting up scaffolding. The cost of scaffolding is based on \$10,000 per event and frequency of use to be once every 10 years.

The total benefit score for Alternative 2 is two times higher than Alternative 1 because of the significant improvement to health and safety and ease of operation. Although the NPV/benefit cost is slightly higher for Alternative 2, the type of improvements make **Alternative 2 - Reservoir Flushing Valves Relocation and Basin Sump Flushing the recommended alternative.**

Table 11-9. Reservoir Flushing Valves and Basin Sump Flushing (Project OKW-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	1	2.00	\$ -	\$ 11,500	\$ 242,531	\$ 121,265	Best Value Alternative
	<i>Definition:</i>	Continue to jet-rod the pipe, when necessary.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system	Capacity Enhancement	3						
	<i>Disadv.:</i>	Difficult to set-up scaffolding in basin to reach valves. Unsafe conditions for jetrodding drain line	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Reservoir Flushing Valves Relocation and Basin Sump Flushing	Health and Safety	5	4.00	\$ 536,000	\$ 1,000	\$ 557,090	\$ 139,272	
	<i>Definition:</i>	Relocate the reservoir flushing valves (RFVs) and piping to downstream of flushing gates and install sump flushing system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Easier to reach RFVs for maintenance; Sump flushing system should eliminate need to access basin when it is partially filled to jet-rod drain lines.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher capital cost.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

11.2.5 HVAC

11.2.5.1 Description of Existing System

The Oakwood CSO facility consists of three buildings. The main building contains the Storm Pump Station, Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, MAU room and hydraulic room. The Basin Odor Control Room contains the odor control systems for the East and West Basins. Table 11-10 provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, gas-fired water heater, emergency shower/eye wash, emergency eye wash, sump pumps, pressure booster pumping system, compressed air system etc. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 11.2.10.

Table 11-10. Major HVAC Equipment at Oakwood CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Main Pump Station	SF-1 to 2	Supply Fan	5,000 CFM
Headworks	MAU-3	MAU	35,800 CFM 3,000 MBH
Basin	EF-20 to 22	3 × Exhaust Fan (East Basin)	52,800 CFM
	EF-23 to 26	3 × Exhaust Fan (West Basin)	52,800 CFM
	SF-5 to 7, SF-10	4 × Supply Fan (East Basin)	52,800 CFM
	SF-5, SF-8 to 10	4 × Supply Fan (West Basin)	52,800 CFM
Chemical Room	AC-2	Air Conditioning Unit	315 CFM 1.25 ton
	MAU-4	MAU	5,000 CFM 400 MBH
	EF-18	Exhaust Fan	2,500 CFM
Electrical Room	AHU-1	AHU	25,000 CFM, Cooling Capacity (125 tons), Heating Capacity (353 MBH)
	EF-35	Exhaust Fan	13,880 CFM
	EUH-8	Electric Unit Heater	1,700 CFM 15 KW
Mechanical Room	AHU-1A	AHU	2,700 CFM
Make-up Air Room	MAU-3	MAU	35,800 CFM
Odor Control Room	EF-28, EF-29	Exhaust Fan	3,000 CFM
	EF-33, EF-34	Exhaust Fan	22,000 CFM
	EUH-6 to 7	Electric Unit Heater	1,700 CFM 15 KW

Table 11-11 provides a summary of the basis of design performance criteria for HVAC systems at Oakwood and Table 11-12 provides the outdoor Basis of Design conditions.

11.2.5.2 Identified Needs and Issues

During the CS-299 Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- Insufficient heating capacity in Headworks Area (served by MAU-3): Upon further investigation, the assessment of insufficient heating was based on the fact that a NPW pipe to one of the screens had burst during a cold period last year. It was determined that this issue was related to a problem with the booster pump system.
- Failed Basin supply air fans and exhaust air fans require replacement: this issue is part of the ongoing HVAC Improvements project (CIP No. 260619).

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- AHU-1 compressor failures: GLWA's HVAC contractor noted that there have been 4 compressor failures with the AHU-1 DX cooling coil in the past 5 years.
- Abnormally short life of Electric Unit Heaters: Per GLWA's HVAC Contractor, the Trane Electric Unit Heaters at Oakwood have a life of 2 to 3 years. The typical expected life of unit heaters that are properly selected for their environment is about 15 years.

Jacobs investigated this issue further. The Trane UHXA unit heaters in the Headworks Area have an aluminum-finned tubular steel heat exchanger that is directly exposed to the air stream in the Headworks Building when the heaters are running. Steel has very poor H₂S resistance and is a poor choice of materials for the environment the unit heaters are in. It is recommended that as the unit heaters fail they are replaced by properly rated units that have a 316 stainless steel heat exchanger and cabinet body, aluminum or 316 stainless steel fins, fan blade, and control enclosure and a motor with a corrosion-resistant protective coating that has passed the ASTM International Standard B117 salt-spray test. As such, this issue should be covered in the SRP.

- Failed Basin supply air fans, maintenance issues, and signs of advanced wear: Several basin supply air fans have failed. There have been bearing failures in the units but there is no access for bearing maintenance. The bearings are greased remotely but there is no way to verify if the grease is getting to the bearings. Despite the fact the units are only 10 years old, the bodies of the units are showing advanced signs of age. GLWA's HVAC contractor does not believe the bases of the units were properly installed; however, the manufacturer provided an inspection in 2020 and concluded that the apparent base settlement was not a concern. As noted above, these fans are being replaced as part of the HVAC Improvements project (CIP No. 260619).

During site investigations (June 2020), the following observations were noted:

- AHU-1 only had one compressor running: Although the weather on the day of the site visit was hot and humid, only one compressor was observed to be running. This underscores that most of the cooling load is driven by the heat generated by electrical equipment, which was not in service on the day of inspection. The main contributors to the cooling load in the space are the VFDs for the stormwater pumps, which rarely run. Jacobs confirmed, however, that the cooling capacity is correctly sized for the predicted heat generated by the electrical equipment when it is in service.
- MAU-4 for the Chemical Room has a complex burner control scheme: Heating output is controlled on MAU-4 by relay packs on each burner. This system is overly complicated and maintenance intensive as each relay represents a potential failure point in the system. GLWA's HVAC contractor noted that they recently had to replace the controller on the unit.

When MAU-4 fails or if maintenance issues become too costly, Jacobs recommends replacement of the unit with one that has a simpler mechanism to modulate the burner output. More efficient units with simpler control schemes are currently available. As such, this issue will be covered in the SRP.

- The Electrical Room was negatively pressurized: The Electrical Room has differential pressure control; however, the area was noted to be negatively pressurized. Electrical rooms are typically positively pressurized to reduce the ingress of dust and corrosive gases into the space. At some facilities, the incoming outside air is filtered with an activated carbon unit to remove H₂S and other corrosive airstream gases.
- MAU-1 has extensive corrosion: Extensive corrosion was noted on the interior of MAU-1. This is most likely the result of backflow of air from the Sanitary Pump Station Room. This MAU is being addressed under the ongoing HVAC Improvement project (CIP No. 260619).

11.2.5.3 Description and Evaluation of Alternatives

As noted above, the major existing HVAC issues and needs are being addressed by the ongoing HVAC capital improvement project. One issue remains and is discussed below. At this time, it is believed that this issue does not require a capital improvement.

AHU-1 Compressor Issues. The extremely high frequency of compressor replacement would suggest that AHU-1 is experiencing abnormal equipment operation. Given the dependence of the peak cooling load on stormwater VFD operation, which occurs rarely, it is likely that the compressors are short-cycling. Jacobs recommended monitoring the compressors using current transformers to determine if this is occurring. As a result of this recommendation, GLWA's mechanical contractor installed a monitoring system in August 2020. Based on review of this data, Jacobs observed that only one of the four compressors (Compressor No. 3) was operating and that it experienced occasions with extremely short cycle times where it was off for less than a minute or only ran for a minute. During the site walkthrough Jacobs noted a compressor was running when the temperature in the electrical room was 75°F despite the fact that the specified sequence of operations calls for AHU-1 to run only if the space temperature exceeds 87°F and that the sequence of operations calls for free cooling to be provided by outside air between a space temperature of 75°F and 87°F. Because AHU-1 was not operating in accordance with the sequence of operations, Jacobs recommended resetting AHU-1 to original factory settings as a next step to potentially reduce short cycle times.

Resetting the AHU did not result in a reduction in short cycle times. Jacobs then contacted Trane, which advised that minimum compressor runtimes and lockout times could be programmed into the unit.

As next steps Jacobs advises GLWA to:

- 1) Work with the mechanical maintenance provider to ensure AHU-1 is functioning as intended per the sequence of operations. As noted above, AHU-1 should economize before running any compressors.
- 2) Verify the cooling temperature setpoint in the space to determine if it has been set to an unreasonably low temperature (outside of the sequence of operations). If the temperature setting is lower than design, Jacobs recommends limiting which users can adjust the cooling setpoint.
- 3) Work with their mechanical maintenance provider to program the unit's compressors to run for a minimum of 15 minutes followed by a minimum lockout time of 15 minutes.

11.2.6 Electrical

11.2.6.1 Description of Existing System

The Oakwood facility's electrical system consists of double ended 4.8 kV, 3,000 A switchgear with dual (redundant) utility feeds, metering of the 4.8 kV feeds and an adjacent DTE substation with two 15 MVA outdoor transformers. The switchgear has a tie-breaker and automatic source transfer controls. Circuit breakers in the switchgear then feed eight storm pumps and two 2,500 kVA outdoor pad mount transformers. The 2,500 kVA transformers then feed a double ended 480 V, 3,200 A switchboard with a key interlocked tie-breaker. Circuit breakers in the switchboard then feed four MCCs and four 125 hp sanitary pumps. The MCCs then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 11-13 provides a summary of the major electrical equipment for this facility.

Table 11-13. Major Electrical Equipment at Oakwood

Location	Major Electrical Equipment	Description
Electrical Room	Double ended 4.8 kV switchgear w/ automatic source transfer	3,000 A, 4.8 kV, 3-Phase
Electrical Room	VFD (Storm Pumps)	(4) 4.8 kV, 3-Phase
Storm Pump Motor Room	Vertical turbine pumps	(2) 1,500 hp, (6) 2000 hp, 4.8 kV, 3-Phase
Outdoors	Pad Mount Transformers	(2) 2,500 kVA, 4.8 kV-480 V, 3-Phase
Electrical Room	Double ended switchboard w/ tie-breaker	3,200 A, 480 V, 3-Phase
Electrical Room	VFD (Sanitary Pumps)	(4) 480 V, 3-Phase
Sanitary Pump Room	Sanitary Pumps	(4) 125 hp, 480 V, 3-Phase
Electrical Room	MCC-1	1,200 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-3	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-4	1,200 A, 480/277 V, 3-Phase

11.2.6.2 Identified Need and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

11.2.6.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project OKW-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure OKW-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Near drain vaults and effluent end of Basin – Add LED lighting fixtures to meet the required foot-candles per IES standards and meet the requirements of the local outdoor lighting ordinances for the areas.
 - Interior Basin at effluent channel – Add interior LED ceiling and wall mounted lighting fixtures within the area to address the required foot-candles and code requirements.
 - External lighting on top of Basin - Add additional light poles and LED lighting fixtures on the facility's basin, lighting foot-candles will meet the requirements of the local outdoor lighting ordinances.
 - Add power receptacles every 100 ft around the exterior of the basin at ground level.
 - Add power receptacles on the top of the basin.

The alternative evaluation is presented in Table 11-14. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$75,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 11-14. Alternative Evaluation for Electrical Improvements (Project OKW-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 262,000	\$ -	\$ 262,000	\$ 74,857	Not Applicable
	<i>Definition:</i>	Add additional lighting near drain vaults and effluent end of basin, interior basin at effluent channel, and top of basin; add power receptacles to assist workers.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

11.2.7 I&C

11.2.7.1 Description of Existing System

Control System: The original Ovation control system was installed in 2012 under PC-755. In 2015 under PC -773D, the Ovation control system controllers and software were upgraded to version O.V.3.5.0.

The existing Ovation system includes remote I/O cabinets located in the Headworks/CSO Basins that are networked to the Ovation controller/I/O cabinets and data concentrator cabinet located in the Communication Room. The system currently has one dual screen operator workstation, plus a database server with wall mounted displays and printers in the Control Room. The Ovation redundant pair of controllers provides the facility with a redundant network, controls and I/O capabilities. A 10 kVA Liebert uninterruptible power supply is used to provide constant power to the Ovation system and network. The Ovation network is equipped with primary and backup network switches. The switches are connected to the GLWA AT&T wide area network via the facility's router. The network connections inside the station are via copper Ethernet cables. All workstations and controller connections have redundant networks. The controller connections are dual-homed to provide system redundancy. Should one network fail, the backup, redundant network is available to provide station monitoring and control. The Ovation system is equipped with a backup radio system to communicate critical monitoring points back to the SCC on wide area network failure.

Flow and Level Sensors: Table 11-15 summarizes the level sensors and flow meters at the Oakwood CSO Facility and Sanitary Pump Station for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 11-15. Summary of Flow Meters and Level Sensors at Oakwood CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Storm Pump Flow Meters	8	Area Velocity
Drain to NWI Meter Vault	1	Magnetic
CSO Facility Level Sensors

Sanitary Surge Relief Chamber	1	Ultrasonic

11.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Operators have indicated the human interface modules (HIMs) for the Chemical Feed Pump VFDs are difficult to operate locally.
- Eliminate basin gas monitoring.
- Minimize fire alarm systems. Elimination of fire alarm systems is not recommended at Oakwood based on the discussion in Section 5.4.7.
- Need for tank level indication at the Chemical Fill Station
- Need for process cameras at select locations to improve monitoring of facility during wet weather operation.
- Update Ovation control system
- Investigate cause of storm pump flow meter failures. Jacobs further investigated this issue. The storm pump flow meters (Teledyne Isco Inc Pro20 HotTap Insertion Meters) have experienced frequent, random outages. Jacobs investigated the issue with the manufacturer Teledyne and with technicians from PCI, who had investigated these meters. According to the Teledyne Isco Inc Pro20 HotTap installation instructions, the meter is suitable for a wide range of pipe sizes, pipe geometries, and varying hydraulic conditions. All of these installation conditions are met, which indicates the meter is being used in the proper application, but an underlying issue is still present, which is causing the random outages. In order to determine the root cause of the issue, a deeper evaluation from an instrumentation contractor familiar with these meters will be required. An allowance of \$50,000 is included in the capital cost estimate to further study this issue.
- Investigate backup flow measurement for each storm pump if the flow meter is not working properly. GLWA requested that Jacobs consider as a backup creating a programmed lookup table to estimate flow based on wet well level and pump curves. Jacobs discovered that this type of backup flow measurement was actually specified to be programmed into the control system according to the 2007 contract documents (Specification 17500 page 12) and may already exist in the software. If it is not included, it could be added by a controls system contractor. Based on this information, a capital improvement is not provided to address this issue.

11.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

I&C Improvements (Project OKW-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation

Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. There are two alternatives for this project:

1) **Alternative 1: Do Nothing/ Replace In-Kind**

- Replace Storm Pump flow meters in-kind
- Leave HIM modules for the Chemical Feed Pump VFDs in place

2) **Alternative 2: I&C Improvements** including,

- Improve local operation capabilities of chemical feed pump HIM
- Eliminate basin gas monitoring
- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations
- Resolve existing storm pump flow meter reliability issues

Each of the I&C related improvements listed above is described further below:

Improve local operation capabilities of chemical feed pump HIM. Operators have indicated the HIMs for the chemical feed pump VFDs are difficult to operate locally. The buttons are small and navigating through the LCD screens is not intuitive or easy to use. The recommendation is to provide local control stations similar to the approach to add local control in Section 5.4.9. The VFD HIM modules would remain for troubleshooting, but operation of the chemical feed pumps will be from the local control stations.

Eliminate basin gas monitoring. Eliminate gas monitoring equipment in accordance with Section 5.4.7.

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

Resolve existing storm pump flow meter reliability issues. This issue should be further investigated by an instrumentation contractor.

The alternative evaluation is presented in Table 11-16. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 includes replacement of the Storm Pump flow meter.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M costs for Alternative 2 include estimated annual O&M for the new cameras and new tank level indicators.

This evaluation shows that Alternative 1 – Do Nothing is the Best Value Alternative. **However, because of the improved reliability, control and operations associated with the I&C improvements, Alternative 2 is the recommended alternative.**

Control System Upgrade (OKW-I&C-2). It is recommended to update the Ovation control system to latest version (O.V.3.7), as described in Section 5.4.2.

Because the Ovation system is the only alternative for the control system upgrade, it is the only alternative considered. Table 11-17 provides the summary of the **Control System Upgrade, which is the recommended alternative.**

Table 11-16. Alternative Evaluation for I&C Improvements (Project OKW-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Replace In-Kind	Health and Safety	3	2.40	\$ 145,600	\$ -	\$ 145,600	\$ 60,667	Best Value Alternative
	<i>Definition:</i>	Replace Storm Pump flow meter in-kind.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to operation - flows and volumes, alarms, system status, etc.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.60	\$ 347,000	\$ 8,000	\$ 515,717	\$ 143,255	
	<i>Definition:</i>	Improve local operation capabilities of Chemical Feed Pumps; eliminate basin gas monitoring; provide tank level indication; and provide process cameras.	Water Quality & Compliance	4						
	<i>Adv.:</i>	Higher performance, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Table 11-17. Alternative Evaluation for Control System Upgrade (Project OKW-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 1,003,000	\$ -	\$ 1,003,000	\$ 334,333	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Replace Sample Building local control panel. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Updates the control system to allow for enhanced performance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.8 Site

11.2.8.1 Description of Existing Site

Access to the site is off Pleasant Street through a 26-ft wide sliding vehicular gate. The parking lot consists of 8-in. thick reinforced concrete pavement. Roads onsite consist of 26 ft wide, 9 in. thick reinforced concrete pavement with 8-in. aggregate base designed to support HS-20 loading. There is also a gravel road going around the basin building consisting of 8 in. of aggregate. Concrete sidewalks are 4 to 5 ft wide and 4 in. thick with a 2-in. sand base. Site security is provided by a perimeter fence comprised of an 8-ft ornamental iron fence and an 8-ft chain-link fence. Stormwater runoff from the site is collected and conveyed to the storm junction chamber upstream of the pump station.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's geographic information system (GIS). Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GP) date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

11.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the following bullets.

- The current road around the basin is gravel and susceptible to potholing .
- There are areas around the basin with poor drainage, including electrical and instrumentation vaults.
- There are several locations around the perimeter of the Control Building where the concrete access sidewalk has settled, leaving uneven cracked flags of sidewalk.
- The following needs are generally preventative maintenance items intended to ensure that the site features or utilities are serviceable throughout their expected service lives.
 - Clear vegetation overgrowth from Surge Relief Basin
 - Seal joints in concrete pavement drive to ensure serviceability

11.2.8.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Site Improvements (Project OKW-SITE-1). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Site Improvements** including,

- Add paved road around the basin
- Address drainage around the basin
- Address drainage in electrical and instrumentation vaults
- Replace settled concrete sidewalk

Each of the site related improvements listed above is described further below:

Add Paved Road Around the Basin. The access service road around the perimeter of the Control and Pump Station Buildings includes reinforced concrete pavement and gutter. However, the access road around the CSO basin is a gravel surface. A number of areas around the perimeter of the basin have experienced poor drainage, that has impacted the service drive, resulting in potholing and reducing accessibility around the CSO basin. It is recommended that the gravel service road be replaced with new reinforced concrete pavement that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. See Figure OKW-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the location of new pavement. The concrete pavement should have a minimum 16-ft width.

Address Drainage Around CSO Basin. There are areas around the CSO basin that are poorly drained. Runoff from the CSO basin roof is collected at six scupper/downspout locations on either side of the basin and discharged to grassy areas at grade between the basin and service road on either side of the basin. These areas do not have significant slope, so basin roof discharge during wet weather tends to accumulate at grade at the base of the basin. The west side of the basin is particularly poorly drained. This may be an area that could benefit from a Green Stormwater Infrastructure solution that would feature a bioswale to collect runoff from the poorly drained grassy area between the basin and service drive. On the basin's west service drive, there is a shallow drainage swale with dimensions of approximately 360 ft by 30 ft. The area tributary to this swale includes areas surrounding its immediate perimeter.

It is recommended that the swale be excavated to increase its volume to accept the flow that is discharged from the west side of the basin roof during wet weather. Figure OKW-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, presents the proposed layout for these improvements. The flat area between the basin and existing service drive is recommended to be regraded away from the basin, and new catch basins and a storm sewer be added to capture the surface runoff and direct the flow under the service drive to discharge into the new bioswale.

Address Drainage in Electrical and Instrumentation Vaults. In the past, the basin electrical/I&C vaults on the west side of the basin had experienced flooding through electrical conduits, allowing groundwater to flow into the vaults. Per discussion with GLWA, the damaged duct-banks have been replaced and the issue of water infiltration into the vaults has been fixed. Having inspected the ground surfaces around the basin, this area should be regraded and the top of the vaults should be adjusted to avoid any surface drainage from going into these vaults. If there is still infiltration into these vaults and there is a desire to keep them free of water, a permanent sump pump should be installed in each vault.

Replace Settled Concrete Sidewalk. There are several locations around the perimeter of the Control Building where the concrete access sidewalk has settled, leaving uneven cracked flags of sidewalk. It is recommended that the damaged sections of sidewalk be removed and replaced to mitigate the potential tripping hazard created by the uneven surfaces. Expansion joints at the base of the building wall should be replaced and caulked to prevent water infiltration.

The alternative evaluation is presented in Table 11-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – Site Improvements has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$209,000, which is a moderate cost compared to other projects recommended in this assessment. However, because of the improved drainage and safety with **Alternative 2 – Site Improvements, Alternative 2 is the recommended alternative.**

Table 11-18. Alternative Evaluation for Site Improvements (Project OKW-SITE-1)

11.2.9 Architectural

11.2.9.1 Description of Existing Facilities

The Oakwood facility consists of chemical room, utility support (electrical and mechanical), control room, odor control room, screen room, sampler room, storm pump room, sanitary pump room, hydraulic room, make-up air room, shipping and receiving and miscellaneous other rooms. The facility also includes the retention basins.

11.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/coverings systems
- Stairways
- Corrosion on visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

11.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (OKW-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove and replace isolation/ cove joint sealant and around building perimeter
 - Remove failed concrete floor coating, clean floor and reseal floor in Headworks and Odor Control Rooms

- Clean rust/ corrosion and coat localized areas in roof framing and beams in the Sanitary Pump Station and Headworks
- Clean and coat corroded areas of vehicle barriers and bollards
- Investigate and repair cause of water intrusion at skylight, between roof decking and skylight installation
- Remove and replace various door hardware and address corrosion on door hardware
- Clean and coat debonding paint from wall
- Clean corrosion of column base plate and apply moisture resistant coat in Pump Station Odor Control Room
- Fasten and replace damaged face brick façade flashing

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure OKW-ARCH-1-ALT-2).

The alternative evaluation is presented in Table 11-19. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 11-19. Alternative Evaluation for Architectural Rehabilitation (Project OKW-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

11.2.10 Safety

11.2.10.1 Description of Existing System

Safety related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

11.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 11-20. The capital improvement project to address these issues is included in the table.

Table 11-20. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Storm Pump Station	Stairway to lower level has excessive gap at landing	Extend railing	Safety Improvements (Project OKW-SAFE-1)
Top of basin	Conduit posing a trip hazard (multiple locations)	Install conduit ramps	Safety Improvements (Project OKW-SAFE-1)
Storm Pump Station lower level	No eyewash and shower present on this level, yet there are containment jugs for hypochlorite, one of which was full and had recently overflowed onto the floor	Add eyewash and shower	Safety Improvements (Project OKW-SAFE-1)
Effluent Sample Room	Eyewash is out of service	Replace eyewash	Safety Improvements (Project OKW-SAFE-1)
Sanitary Pump Room	Illuminated exit sign not working	Replace exit sign	Exit Sign Improvements ^a
Basin Odor Control Room	Illuminated exit signs not working	Replace exit signs	Exit Sign Improvements ^a
Chemical Room	Gaps between ladder and tanks 1 and 2 at top of ladders are too large	Install step platform	Safety Improvements (Project OKW-SAFE-1)
Storm Pump Station	Gaps between ladder and motors at top of ladders are too large	Install step platform	Safety Improvements (Project OKW-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

11.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of project alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project OKW-SAFE-1). This project should address the safety issues identified above. These issues include:

- Extend railing on the stairway in the Storm Pump Station to eliminate fall hazard
- Install conduit ramps at the top of basin to eliminate trip hazard
- Replace eyewash/shower in the Storm Pump station, Effluent Sample Room, and Sanitary Pump Room
- Install step platform between ladder and tanks 1 and 2 at top of the ladder in the Chemical Room

- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency, the Table 11-21 showing the one alternative is presented below.

Table 11-21. Alternative Evaluation for Safety Improvements (Project OKW-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 338,000	\$ -	\$ 338,000	\$ 112,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address tripping hazards, fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Oakwood CSO Facility.

11.2.12 Storm Pump Station

11.2.12.1 Description of Existing System

The storm water pump station consists of eight vertical mixed flow pumps. Design criteria is presented in Table 11-22. The pump station is divided into two equal sized wet wells. Each wet well contains one smaller pump and three larger pumps. The storm pumps are equipped with an external flushing water system for bearing cooling and lubrication. The seal water system consists of potable water piping with a dedicated seal water booster pump for each storm pump. As the wet wells fill, the storm pumps start based on the wet well levels and control system logic. The station was designed for operation using a constant-level control strategy. Features of this control strategy include narrow wet well operating range, pump speed ramping up and down, and pumps turning on/off to match a set level. This requires pumps with VFDs and a high degree of turn-down capability for the pumps.

Table 11-22. Design Criteria for Oakwood Storm Pump Station

Storm Pump No.	Design Capacity, MGD	Total Dynamic Head, ft	Drive Type
1 and 2	97	48	VFD
3, 4, 7, and 8	178	48	Constant Speed
5 and 6	178	48	VFD

11.2.12.2 Identified Needs and Issues

For the Storm Pump Station, Jacobs examined existing conditions and obtained information from O&M staff members. Many of the stormwater pumping issues were evaluated separately in a report by Brown and Caldwell dated January 15, 2019. Jacobs confirmed in June 2020 that it appeared the recommendations for the stormwater pumps had not yet been implemented.

SP1 and SP2 (small pumps) were found to have an unstable operating zone below 60 MGD at typical wet well levels and motor speeds below approximately 85 percent. Currently, the majority of SP1 and SP2 operating time is at a motor speed of 75 percent within this unstable zone. SP5 and SP6 have an unstable zone below 110 MGD (motor speeds below 80 percent). SCADA data documents significantly increased pump vibration levels and rapidly fluctuating discharge flowrates while operating in this unstable zone. Pump operation outside of the preferred operating range (POR) and especially in the unstable zone will lead to diminished reliability. Anticipated consequences include increased rate of failure of bearings and seals. The low annual runtime of the pumps may mask reliability issues related to the poor operating conditions. The recommended discharge-flowrate turn-down range for SP1, SP2, SP5 and SP6 is significantly less than the original design intent. Pumps SP3, SP4, SP7, and SP8 operate in a stable zone at all normal operating conditions.

The storm pumps operate within a narrow range of wet well levels. The pump net positive suction head (NPSH) margin was analyzed, and based on the analysis performed, it may be possible to start pump operations at a lower wet well level.

Based on this information, it was recommended that the operating setpoints be modified and tested. The potential setpoint modifications include the following:

- Operate SP1 and SP2 within a speed range of 85 to 100 percent to avoid unstable operating zones. Jacobs confirmed that, as of June 2020, this modification had not yet been made.
- Operate SP5 and SP6 within a speed range of 85 to 100 percent to avoid unstable operating zones. Jacobs confirmed that, as of June 2020, this modification had not yet been made for SP6.
- Lower lead pump shut-off WSE from EL 71-ft to EL 65-ft to reduce pump cycling on/off. Prior to implementing this recommendation, at a minimum, the submergence should be calculated for the large pumps using the equation in ANSI/HI 9.8 (Pump Intake Design) to determine if the proposed minimum WSE is feasible. A more robust study would be to perform physical model tests for low water level for the large storm pumps.
- For the near term, modify controls to provide continuous seal/lube water to all storm pumps to prevent clogging of seal water lines. Note that the facility SOP indicates that the "seal water system" is to be run continuously if the storm pump wet well level is above the bell of the storm pumps. Consider whether the modified controls will allow the seal water to run at a lower than advised wet well level, implications, and modifications to run seal water continuously under appropriate conditions. Jacobs confirmed that, as of June 2020, the seal water pumps run continuously.

The seal water systems for the storm water pumps were found to experience various operational issues. Previously, tripping of the seal water booster pump circuit breakers frequently caused failure of the storm pumps. This issue was addressed by replacing the breakers. Recently, the seal water lines have become plugged and proved difficult to clear. These events coincided with the blinding of bar rack in the sanitary PS. Because the racks were blinded, the sanitary sewage level in the storm wet well raised to nearly EL 70-ft. Exposure of the storm pump bearings to sanitary sewage floatables may have plugged the bearing flushing lines.

11.2.12.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Rehabilitate Storm Pumps (Project OKW-PUMP-1). This project would include removal of each pump for inspection in the factory and necessary rehabilitation of all eight storm pumps. The conversion of the water bearing lubrication system with a grease bearing lubrication system would be included to alleviate the plugging problems experienced in the past. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.** Continue to operate pumps in existing condition and rehabilitate at some time in the future.
- 2) **Alternative 2: Rehabilitate Storm Pumps.** This alternative includes removal of all pump rotating assemblies for inspection and rehabilitation, as necessary. The alternative also includes conversion of all pumps from a water bearing lubrication system to a grease lubrication system. This task should include: Confirm details of required modifications with pump manufacturer (Xylem/Flygt); identify the recommended type of grease; determine where the excess water for motor bearing cooling and seal water services would be conveyed (enclosing tube typically fills with grease); modifications required to seal the bottom of enclosing tube around the shaft to prevent wastewater/ grease mixing in tube; and, obtain state regulator buy-in for this modification.

This task should also evaluate and recommend the feasibility of lowering the lead pump shut-off water surface elevation from EL 71-ft to EL 65-ft in an effort to reduce pump cycling on/off. This task may require physical model tests for the large storm pumps.

The alternative evaluation for these alternatives is presented in Table 11-23. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

Due to the importance of reliable storm pumping after the diversion of additional flow from the NWI in the near future, **Alternative 2 – Rehabilitate Storm Pumps is the recommended alternative.**

Table 11-23. Alternative Evaluation for Rehabilitate Storm Pumps (Project OKW-PUMP-1)

	<i>Adv.:</i>	More reliable operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Regulatory concerns with grease in wastewater	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

11.2.13 Sanitary Pump Station

11.2.13.1 Description of Existing System

The Sanitary Pump Station of the Oakwood CSO Facility consists of two separate wet wells (east and west) and an enclosed sanitary pump station room located at ground level. Each wet well includes a manual bar screen and two submersible sanitary sewage pumps for a total of four pumps. Even number pumps (SN2 and SN4) are located in the east wet well, while odd numbered pumps (SN1 and SN3) are located in the west wet well.

11.2.13.2 Identified Needs and Issues

For the Sanitary Pump Station, Jacobs examined existing conditions and obtained information from O&M staff members. Many of the sanitary pumping issues were evaluated separately in a report by Brown and Caldwell dated January 15, 2019.

The manual bar screen frequently become blinded, resulting in differential water levels of 12-15 ft from upstream to downstream of the bar racks. This can contribute to submergence of the storm pump intakes during dry weather flow. This issue is evaluated in the Screening section above and removal of the bar racks is recommended.

In general, the pumps have normal annual pump runtimes. Operation of east and west wells is imbalanced due to failure of the Influent Junction Chamber isolation pinch valves. Modifications to the Influent Junction Chamber are discussed in the Dewatering and Flushing section above.

The new Flygt pumps are expected to run over a range of static head that spans wet well elevation 78 down to wet well elevation 43.6, a static head range of 34.5-ft between low wet well elevation and high wet well elevation. These pumps are operating without VFDs. The Flygt pumps operate to the right side of the best efficiency point (BEP) for most operating conditions. At low wet well elevations, the pumps operate most efficiently at approximately 83 percent speed. At high wet well levels, the pumps run well to the right of the POR (nearly off of pump curve) under all speeds. At target dry weather wet well elevations, the pumps run between the minimum and maximum POR only at a pump speed of 75 to 85 percent.

When the storm pumps are operating and there is no wet weather capacity in the downstream sewer to the NWI, the control system should automatically operate the sanitary pumping system in recirculation mode, to minimize settling of grit and solids within the sanitary pump wet wells. (It is currently operated in manual.) Recirculating sanitary flow during wet weather events may be delaying the time it takes to empty the wet well and wasting energy. However, the cost/down time associated with unclogging pumps may outweigh the energy utilized to recirculate flow.

The maximum firm capacity from Sanitary PS is approximately 15 to 20 MGD. The minimum recommended flowrate for the Storm PS is approximately 65 to 75 MGD. The dead band between these two capacities significantly limits ease-of-operations for small and intermediate sized storm events based on current operating strategies.

11.2.13.3 Recommendations

The following actions are recommended to address issues identified with the sanitary pumps:

- Modify operating setpoints and test new operation. Testing would include the further development of proposed new operating procedures and setpoints, coordination with GLWA Oakwood CSO O&M staff

GLWA field Services O&M staff and execution on one or more storm events. Update O&M manual with the new operating procedures

- It is recommended that the manual operated bar racks be removed to prevent sewage backup into the storm pump intakes. See Screening Section 11.2.1 above for further discussion.

11.2.14 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Oakwood CSO facility, Table 11-24 and Table 11-25 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 11-24 and Table 11-25, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

^a The Oakwood – Pumping Station Building was not evaluated.				

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near

future. Based on the review of the Oakwood Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

11.3 Capital Planning for Oakwood CSO Facility

11.3.1 Summary of Capital Improvement Plan Projects

Table 11-26 provides a summary of the recommended CIP projects and associated capital costs for the Oakwood CSO facility based on the alternative evaluations conducted for this facility.

Table 11-26. Summary of Recommended Projects at Oakwood CSO Facility

Project No.	Alternative	Description	Total Project Cost
OKW-SCR-1	2	Remove Bar Racks	Capital Outlay
OKW-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 443,000
OKW-DIS-2	2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
OKW-DIS-3	1	Reline and Provide Side Access Manways	\$ 289,000
OKW-FD-1	2	Influent Junction Chamber Isolation Improvements	\$ 289,000
OKW-FD-2	2	Reservoir Flushing Valves Relocation and Sump Flushing	\$ 536,000
OKW-ELEC-1	2	Electrical Improvements	\$ 262,000
OKW-I&C-1	2	I&C Improvements	\$ 347,000
OKW-I&C-2	1	Control System Upgrade	\$ 1,003,000
OKW-SITE-1	2	Site Improvements	\$ 732,000
OKW-ARCH-1	2	Architectural Rehabilitation	\$ 880,000
OKW-SAFE-1	1	Safety Improvements	\$ 338,000
OKW-PUMP-1	2	Rehabilitate Storm Pumps	\$ 4,100,000

11.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 11-27. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 11-27. Capital Improvement Plan Projects for Oakwood CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
OKW-1 Disinfection System Improvements	\$ 1,424,000	2026 <i>Timing based on implementation of projects before NWI diversion to ensure reliable operation with increased flows.</i>	OKW-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 443,000
			OKW-DIS-2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 156,000
			OKW-DIS-3	Reline and Provide Side Access Manways	\$ 289,000
			OKW-FD-1	Influent Junction Chamber Isolation Improvements	\$ 289,000
			OKW-FD-2	Reservoir Flushing Valves Relocation and Sump Flushing	\$ 536,000
OKW-3 Facility-Wide Electrical and I&C Improvements	\$ 1,612,000	2029 <i>Timing based on asset condition</i>	OKW-ELEC-1	Electrical Improvements	\$ 262,000
			OKW-I&C-1	I&C Improvements	\$ 347,000
			OKW-I&C-2	Control System Upgrade	\$ 1,003,000
OKW-4 Site Improvements	\$ 732,000	2030 <i>Timing based on best judgement</i>	OKW-SITE-1	Site Improvements	\$ 732,000
OKW-5 Facility-Wide Safety and Architectural Improvements	\$ 1,218,000	2023 <i>Project should be initiated as soon as possible</i>	OKW-ARCH-1	Architectural Rehabilitation	\$ 880,000
			OKW-SAFE-1	Safety Improvements	\$ 338,000
OKW-6 Rehabilitate Storm Pumps	\$ 4,100,000	2022 <i>Timing based on condition</i>	OKW-PUMP-1	Rehabilitate Storm Pumps	\$ 4,100,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 11-28 and Table 11-29 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 11-28 indicates that OKW-DIS-1 project has 52 assets that have an average condition score of 1.15 and an average replacement date of 2041. However, this project should be completed before the NWI diversion to ensure reliable operation with increased flows and therefore, the project was proposed a scheduled construction completion date of 2026 instead of 2041.

Table 11-28. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
OKW-DIS-1	52	1.24	1.15	1.95	23	2041	\$ 1,819,300
OKW-DIS-3	2	2.14	1.00	3.21	15	2035	\$ 118,400
OKW-I&C-1	8	1.14	1.91	2.24	15	2031	\$ 145,600
OKW-I&C-2	1	2.29	1.57	4.08	12	2029	\$ 580,725

Table 11-29. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
OKW-DIS-1	1	1.29	5.00	4.50	10	2021	\$ 145,000

11.3.3 20-Year Capital Outlay Plan

Table 11-30 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 11-30. 20-Year Capital Outlay Plan for Oakwood CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 671,213	\$ 20,010	\$ 30,000	\$ -	\$ 145,000	\$ -	\$ -	\$ 429,435	\$ -	\$ -	\$ 46,768	\$ -	\$ -
2022	\$ 1,574,631	\$ -	\$ -	\$ 26,883	\$ -	\$ -	\$ 1,534,700	\$ -	\$ -	\$ -	\$ 13,048	\$ -	\$ -

Total	\$ 14,598,975	\$ 594,888	\$ 1,292,697	\$ 4,542,042	\$ 2,468,144	\$ 65,583	\$ 1,685,661	\$ 2,424,000	\$ 143,464	\$ 735,645	\$ 430,062	\$ 94,996	\$ 121,792

Notes:

Explanation of large capital outlays in first two years:

- Screening System: The screen spray water booster pump in the makeup air room was out of service at the time of the Condition Assessment. GLWA has repaired this asset since then.
- Retention System: Two reservoir fill valves (Nos. 3 and 5) in the West Basin (\$6,900 each) received a score of 5 because the valves may not open again if they are closed. One drain valve (DV-7; \$13,000) received a score of 5 because the valve body was removed from the pipeline.
- Disinfection System: One chemical feed pump (No. 6) received a score of 5 since the pump had been removed from the skid at the time of the Condition Assessment.
- Odor Control System: One carbon scrubber in the basin Odor Control Room received a score of 5 because the unit was not in service at the time of the Condition Assessment.
- HVAC System: Three exhaust fans (EF-5, EF-20, and EF-24) and four supply fans (SF-7 to 10) received a score of 5 since they have been out of service for some time. An ongoing HVAC project is addressing these units.

12. Puritan-Fenkell CSO Control Facility

12.1 General Facility Description and Future Capacity Considerations

12.1.1 General Facility Description

The Puritan-Fenkell CSO Facility is an RTB with 2.8 MG of storage and a treatment capacity of 845 cfs. It was constructed in 1996. The facility has not experienced the originally anticipated level of flows, in fact, the facility did not discharge from 2016-2018 and only a few times in 2019 and 2020. For this reason, Section 12.1.2 describes potential modifications to make this facility into a "Capture-Only" facility. A similar recommendation is made for Seven Mile CSO Facility.

The facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

12.1.2 Modifications to Make Puritan-Fenkell Facility into a Capture-Only Facility (PF-WWMP-1)

The WWMP recognized that "GLWA has developed a protocol to operate the Puritan-Fenkell and Seven Mile basins in capture-only mode (no treatment or discharge) for flows up to the 10-year 1-hour design storm. This finding provides a significant water quality benefit because the 1,114-acre service area can be captured, stored, and returned to the WRRF following a storm event preventing release of an estimated 700 million gallons of CSO each year."

Operating these two facilities in capture mode would allow for the cost avoidance of operating and maintaining the hypochlorite feed and storage systems and it would likely not require operations labor to be onsite during a storm event. Screening the influent flow is still recommended, particularly since the screens are already installed, to prevent large debris from entering the capture basin.

Wade Trim conducted a study ("Puritan-Fenkell and Seven Mile CSO Retention and Treatment Basins Basin Collection System and Hydraulic Analysis", dated August 29, 2019). This hydraulic study included an analysis "to evaluate the potential of operating the basins in capture-only mode as a possible operational protocol for the system. Capture basin operation was evaluated to understand the impacts on untreated overflow from the 17 Main Rouge River outfalls on the Detroit West Side system, flooding impacts of the utility tunnels within the two basins, and the risk of upstream basement flooding."

The findings of the study included:

- Limited (approximately 2 percent) increase in untreated overflow from the 17 Main Rouge River outfalls as a result of capture mode operation.
- Impact to the utility tunnels when operating in capture mode is expected for design storms between the 10-year, 24-hour and the 25-year, 24-hour storm at the Puritan-Fenkell basin. At the Seven Mile basin, design storms slightly smaller than the 10-year, 24-hour storm will begin to impact the utility tunnel.
- The evaluation of basement flooding risk shows the basins can be operated in capture mode for the 10-year, 24-hour storm without risk of basement flooding. However, during the 25-year, 24-hour storm significant basement flooding can be expected.

The report concluded that operating the basins in capture-only mode in their current configuration is not recommended due to the risk of basement flooding. The report indicated, however, that capture-only mode may be possible if high level emergency overflows are added to the basins to relieve the system during extreme events to protect basements from flooding.

To aid in the analysis of operating both Puritan-Fenkell and Seven Mile as capture-only basins, conceptual cost estimates have been generated under CS-299 for both facilities including capital improvements listed below. The Wade Trim hydraulic study provided some details regarding these issues, which are included in the description of the conceptual cost estimate; however, additional study and design will be needed.

- 1) Emergency overflow relief. The current weir wall is about 12 ft high at both facilities. A new weir wall about 20 ft high and associated structural modifications are needed at the effluent end of the basin to construct a taller weir wall (see Figure 12-1). The length of weir was not reported and should be included in the future study.
- 2) Utility tunnel flooding protection. Water-tight doors are recommended where there is access to the basin from the utility tunnel and at the influent end of the utility tunnel. The proposed doors can withstand 20-ft of static head.
- 3) Replace the existing effluent butterfly gates with flap gates. The Wade Trim report evaluated two different locations for these gates at each facility, which would prevent backflow into the facility (see Figure 12-2). Additional study should be performed to determine if these flap gates are still needed with the taller proposed weir wall.

Figure 12-1. Proposed Modification to Effluent Weir Wall for Emergency Overflow Relief

Figure 12-2. Potential Options for Flap Gate Retrofit – Puritan-Fenkell (from Wade Trim Report)

A preliminary life-cycle comparison is presented in Table 12-1. Alternative 1 represents the scenario where the facility continues to operate as an RTB. Alternative 2 represents a scenario where the facility operates in the complete capture mode. The intent of this comparison is to present the cost of the emergency overflow weirs and flap gates compared to the avoided costs associated with maintaining the disinfection system and flow meters for the flow-through treatment mode of operation. The following costs are used in this evaluation:

- The period of evaluation is assumed to be 50 years, which represents an approximate remaining life of the basin.
- For Alternative 1, the capital costs were obtained from the SRP replacement costs and include the chemical feed pumps, drives, piping, and storage tanks. It also includes the flow meters for the effluent and shunt channel. It is assumed for this analysis that all of these assets would be replaced twice during the period of evaluation.
- For Alternative 1, the O&M costs include those items that are currently needed, but would no longer be needed under a complete capture mode. These costs include Operations labor before and during storm events to make the facility ready for discharge, if necessary (assumed to be 8 storm events per year and 10 hours per storm event). Costs also include hypochlorite usage or degradation of the hypochlorite in one tank (4,000 gallons) every six months at a unit cost of \$0.90 per gallon.
- For Alternative 2, the total project cost for the modifications described for the emergency weirs and flap gates is provided in Volume 6 – Appendices, Appendix C, under PF-WWMP-1. The costs also include permitting and modeling to demonstrate and coordinate the modifications with Michigan EGLE.

As shown in Table 12-1, the Best Value Alternative is Alternative 2 – Convert to Complete Capture Basin. As such, it is recommended that this alternative be pursued through additional modeling to confirm water levels in the collection system during peak storm events and coordination with Michigan EGLE.

Table 12-1. Alternative Evaluation for Puritan-Fenkell Convert to Complete Capture Basin

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ 2,836,400	\$ 15,200	\$ 3,702,286	\$ 1,480,914	
	<i>Definition:</i>	Do nothing. Continue to operate as an RTB	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system; no new regulatory issues	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher level of operator attention during storm events. Must maintain hypochlorite storage and feed system.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Convert to Complete Capture Basin	Health and Safety	4	3.72	\$ 2,600,000	\$ -	\$ 2,600,000	\$ 699,552	Best Value Alternative
	<i>Definition:</i>	Convert to Complete Capture Basin	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less operator attention during storm events. No O&M for hypochlorite system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires regulatory approval; Modeling confirmation of acceptability	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	5						

12.2 Facility Assessment

12.2.1 Screening

12.2.1.1 Description of Existing System

The Puritan-Fenkell CSO Facility has three mechanically cleaned bar screens that were installed in 1996. Influent wastewater from a 12-ft diameter influent sewer enters the headworks area of the facility and flows through the screens into the basin compartments. Material collected by the screens is mechanically raked from the bar screens and deposited into a dumpster to be hauled to the landfill.

Table 12-2 provides an overview of the existing screening system at Puritan-Fenkell CSO facility.

Table 12-2. Overview of Existing Screening System at Puritan-Fenkell CSO Facility

Parameter	Value
Treatment Capacity (cfs)	845
No. of Screens	3
Manufacturer	Jones and Attwood
Screen Type	Catenary Bar Screen
Opening Size	0.5-in. spacing
Depth or Length / Width	29 ft 1 in / 9 ft 4 in
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

12.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the screens:

- Provide screening retention plate along entire conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt.
- Replace conveyor belt as corrugated sidewall part of belt has torn off from large sections of the belt.
- Need for automatic start for screens and belt.
- Change location of screen controls.
- Prevent screens from swaying during operation. During higher flow events, the screens reportedly sway to some degree. The operators believe this is caused by the returning rake getting tossed by the rapid flow of water and affecting the rest of the screen. They noted that the Conner Creek screens (which is a similar screen but does not sway) has chain guide returns that extend closer to the floor of the channel. This issue was added to the scope of the OEM evaluation; however, the OEM was unable to see the swaying because flow did not occur during the site visit. If this issue causes problems in the future, it should be video-taped to document the issue.

- Address worn teeth on screen rakes. The OEM condition assessment assessed the condition of the screen components. They noted some rakes had a significant amount of corrosion, but they did not indicate the need for replacement.
- Provide improved means to install stop logs in influent area. GLWA requested a means for installing the stop logs with a permanent type of system. The channels for the stop logs for each screen are very close to Headworks building wall (see drawing in Figure 12-3). The reach of the overhead crane is unable to lower the logs directly into place.

Figure 12-3. Location of Stop Log Guides at Puritan-Fenkell Headworks

It should be noted that a sluice gate is proposed upstream of the sanitary pumps (and downstream of the screens) in the Flushing and Dewatering section (Section 12.2.4). This will allow isolation of the sanitary wet well from the rest of the facility.

It should also be noted that one of the screen channels has the influent channel running through the bottom of the opening. It is not clear how the existing stop log were intended to stop flow, given the 2 ft by 2 ft channel running through the bottom of the channel floor. Furthermore, all of the stop logs would need to be installed (and the channel properly isolated) to isolate the screen channel during a wet weather event because there is no stop log on the downstream side of the screen.

Jacobs investigated installing sluice gates. Based on the hydraulic profile, gates with 18 ft height and 10 ft width would be needed. This size would require two leaf gates; however, there is not enough room for two leaves. The gates could be shorter height if designed for a smaller storm event. Then, one gate could be used. The proposed gates would normally reside in the “up” position, out of the water channel and be lowered using an actuator when needed.

Given the infrequent need for installing the stop logs and the redundancy of the screens, it is suggested that a temporary means of installing the stop logs should be utilized when screen replacement or major rehabilitation is required.

12.2.1.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Screening Improvements (Project PF-SCR-1). Due to the relatively small nature of some of the screening-related issues identified as improvements, all of the identified screening improvements are proposed to be in one project – Screening Improvements. This project could be split into multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Screening Improvements** including,

- Screening retention plate along entire conveyor
- New conveyor belt
- Provide programming modifications for automatic start for screens and belt
- Relocate screen controls.

Each of the screening related improvements listed above is described further below:

Screening Retention Plate Along Entire Conveyor. Screenings from the screens occasionally fall off the conveyor at the back of the screens. A screenings retention plate would guide the discharged screenings to the middle of the conveyor belt. A cost for a screening retention plate (similar to screening retention plate at Conner Creek) is included in the capital cost estimate.

New conveyor belt. A new conveyor belt is recommended, as opposed to rehabilitating the existing belt. The cost estimate includes a new belt.

Provide programming modifications for automatic start for screens and belt. Programming modifications to provide automatic start of the screen and conveyor belt based on influent water level (for the screens) and start of screens (for the conveyor belt).

Relocate screen controls. The screen control box is located on the wall next to the conveyor. During screening operation, access to this location requires the operator to stand by a discharging screen. Although the screening plate may reduce splatter, it may still occur.

The alternative evaluation is presented in Table 12-3. The sources of costs used in this evaluation are listed below:

- Capital costs for Alternative 2 are presented in Volume 6 – Appendices, Appendix C under this project title.
- The difference in O&M costs between the two alternatives will be negligible.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$66,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Screening Improvements is the recommended alternative.**

Table 12-3. Alternative Evaluation for Screen Improvements (Project PF-SCR-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Operator needs to be present to start screen.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Screening Improvements	Health and Safety	4	3.50	\$ 230,000	\$ -	\$ 230,000	\$ 65,714	Not Applicable
	<i>Definition:</i>	Provide screening retention plate, new conveyor belt, automatic screen and conveyor	Water Quality & Compliance	3						
	<i>Adv.:</i>	Operator does not need to be present to start screen, cleaner/safer operation	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.2 Disinfection

12.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, four gear pumps, two induction mixers, and two in basin mixers. There are three screens discharging into a common influent channel to Basins 1 or 2. There are two induction mixers located upstream of the bar screens and two submersible mixers with chemical feed, one in each basin. The sodium hypochlorite pumps discharge to a common header with a flow meter that splits to the two induction mixers, Basin 1 mixer, and Basin 2 mixer. Although there are flow indicators after the split to the two induction mixers, flow splitting is not metered and there does not appear to be any basis to achieve equal flow splitting. Currently, operations primarily feed to the basin mixers and if they suspect a strong chlorine demand in the influent, they will also feed to the two induction mixers in the influent.

Table 12-4 provides an overview of the existing disinfection system at Puritan-Fenkell CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 12-4. Overview of Existing Disinfection System at Puritan-Fenkell CSO Facility

Parameter	Value
Treatment Capacity (cfs)	845
Design Feed Strength (% hypochlorite)	5

12.2.2.2 Identified Needs and Issues

The needs and issues identified for Puritan-Fenkell were identified from meetings with O&M staff and Jacobs team site visit and investigations. These needs and issues are summarized as follows:

- Chemical feed system. In addition to the desire to standardize on one or two types of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Puritan-Fenkell chemical feed system has the following issues:
 - No flow metering to individual feed points to control the feed split
 - Consider need to enlarge area to accommodate alternative type of pumps.
 - Evaluate possibility of gravity feed from the chemical tanks with a meter and control valve. Jacobs evaluated the possibility of this type of feed system. The effluent weir from the CSO basins

controls the hydraulic grade line at the influent induction mixers to above elevation 124 once the basin is filled. The bottom of the sodium hypochlorite tanks are at approximately elevation 142 and the maximum liquid depth is approximately 8 ft. Thus, there is approximately 18 ft of static head available with the tanks empty and 26 ft with the tanks full. This corresponds to 7.8 pounds per square in. gauge (psig) empty to 11.2 psig full available head. The induction mixers require back pressure valves to prevent siphoning chemical. Evoqua recommends a setting of 15 psig. Therefore, the available static head is inadequate for gravity feed before even accounting for friction loss and flow control valve loss. Thus, continued pumping as the means of chemical delivery is recommended.

The first two issues are addressed in Replace Chemical Feed System (Project PF-DIS-1).

- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common. This issue is addressed in Provide Flow-paced and TRC-paced Automated Chemical Feed (Project PF-DIS-2) below.

12.2.2.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Replace Chemical Feed System (Project PF-DIS-1). The alternatives to address the common chemical feed system issues among most of the CSO facilities were presented in Replace Chemical Feed System (Section 5.2.2). It should be noted that the project, PF-DIS-1, would address the additional chemical feed system issues identified in the previous section. Alternatives include:

- 1) **Alternative 1: Replace Existing Chemical Feed System In-Kind.** This alternative would generally replace the existing feed system in-kind. If this alternative were to be selected, minor improvements to address some identified issues could be considered; however, Jacobs did not specifically evaluate any individual improvements to the existing system; rather, the focus was on the identified alternatives.
- 2) **Alternative 2: Chemical Feed Utilizing Standardized Pump Distribution and Hose Pumps.** The major advantage of this alternative is that it is easier to control as one pump is dedicated to a channel.

It should be noted that hose pumps will be larger than the existing gear pumps and the need to enlarge the pump area was considered to verify the feasibility of this alternative. The Bredel 65 pumps have a base of 29 in. by 28 in. The pump and motor cantilever beyond the base plate and pad and have maximum dimensions of 42 in. by 46 in. The existing pump area is about 5 ft wide and 18 ft long excluding the doors. If one pump were provided per feed point using the pump distribution alternative, then there would be 5 pumps including a spare. This would fully consume the approximate 18 foot length with no space between the pumps for maintenance or access. Thus, the pump area would need to be expanded for this alternative. The separate pump containment could be eliminated, and the pumps located on pads at a sufficient height for spill protection. This is reflected in the cost estimate for this alternative.

- 3) **Alternative 3: Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps.**

The alternative evaluation for these alternatives is presented in Table 12-5. The sources of costs used in this evaluation are listed below:

- The capital cost for Alternative 1 were obtained from the replacement costs of the SRP.

- The capital cost for Alternative 2 and 3 is included in Volume 6 – Appendices, Appendix C under this project title.
- The O&M cost for Alternative 1 were estimated based on manufacturer pump rebuilds at a cost of \$7,500 per year.
- O&M costs for Alternative 2 were developed based on input from hose pump manufacturer for annual lubrication and hose replacement, and rebuild of the pumps at Year 10.
- O&M costs for Alternative 3 were estimated based on pump rebuild cost of \$20,000 per pump at Year 10. This frequency is based on GLWA experience at Conner Creek.

Table 12-5 shows that the Total Benefit score of Alternatives 2 and 3 are 1.5 higher than Alternative 1 (Do Nothing) due to improved ease of O&M and improved component performance, which should lead to more consistent and reliable water quality compliance. Based on having the lowest NPV/Benefit cost, **Alternative 3 - Chemical Feed Utilizing Standardized Manifold Pump Distribution and Centrifugal Pumps is the Best Value Alternative. As such, this is the recommended alternative.**

Note that this project would not be recommended if the basin is converted to complete capture.

Table 12-5. Alternative Evaluation for Replace Chemical Feed System (Project PF-DIS-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Replace Existing Chemical Feed System in-kind	Health and Safety	3	2.08	\$ 340,000	\$ 7,500	\$ 498,172	\$ 239,123	
	<i>Definition:</i>	Replace existing chemical feed system.	Water Quality & Compliance	2						
	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Existing system is difficult to operate and maintain and has performance issues with	Component Performance	1						
	<i>Comments:</i>	None	O&M Ease	1						
2	<i>Alt. Name:</i>	Chemical Feed utilizing Standardized Pump Distribution and Hose Pumps	Health and Safety	3	3.60	\$ 687,000	\$ 4,410	\$ 780,005	\$ 216,668	
	<i>Definition:</i>	Upgrade chemical feed system to individual pump distribution system with one pump per	Water Quality & Compliance	4						
	<i>Adv.:</i>	Easier control as one pump is dedicated to a channel.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Lots of pumps and valves, allows for an installed redundant pump but manual	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						
3	<i>Alt. Name:</i>	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	Health and Safety	3	3.60	\$ 383,000	\$ 3,000	\$ 446,269	\$ 123,964	Best Value Alternative
	<i>Definition:</i>	Upgrade chemical feed system to manifold pump distribution system with multiple pumps	Water Quality & Compliance	4						
	<i>Adv.:</i>	Less pumps and valves for easier maintenance. Redundant pump is installed and easily	Capacity Enhancement	3						
	<i>Disadv.:</i>	Not quite as energy efficient. Maintenance of flow control devices to equalize flows to each	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Provide Flow-paced and TRC-paced Automated Chemical Feed (Project PF-DIS-2). As with the other CSO facilities, the chemical feed system does not work in automatic. Consistent dosing in response to rapid changes in flow requires flow pacing. Refinement of the hypochlorite dose in response to changes in chlorine demand requires automated adjustment of the target dose using an online TRC analyzer.

The alternatives to address this issue were presented in Provide Flow-Paced and TRC-Paced Automated Chemical Feed (Section 5.2.3). The alternatives include:

- 1) **Alternative 1: Continue Manual Adjustment of Chemical Feed.** This alternative would continue to use the existing level of controls and automation for the chemical feed system in which the operators manually adjust chlorine feed. The storm pump flow meter readings would continue to be used by the operator to adjust the chlorine feed rates.
- 2) **Alternative 2: Provide Flow-paced and TRC-paced Chemical Feed Control System.** This alternative would automatically adjust chemical flow based on storm pump flow rate and also utilize the sampling and analysis of wastewater from a point a relatively short distance downstream of the chemical dosing point to further adjust chemical feed flows. The sampling location would be near the influent end of the basin and near the bottom portion of the basin (to be able to measure TRC concentrations before the effluent sample point).

The automatic chemical feed system will require less operator input during an event. However, there will be increased maintenance of the TRC system by GLWA staff (either lab technicians or operators) during the storm and during dry weather. The annual O&M cost includes costs for maintaining the TRC monitors.

The alternative evaluation is presented in Table 12-6. The sources of costs used in this evaluation are listed in the following bullet:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The annual O&M cost for Alternative 2 assumes that a lab technician or operator would need to perform inspection/maintenance of the TRC analyzers on a routine basis to make sure it remains functional between storm events.

Although Alternative 1 does not require any additional capital or O&M, it does not address the fact that the TRC goal may not be met every event. Alternative 2 provides the best opportunity to meet the effluent TRC goals in the NPDES permit. **Based on the improved ability to meet the NPDES permit TRC goal, Alternative 2 – Provide Flow-paced and TRC-paced Chemical Feed Control System is the recommended alternative.**

Note that this project would not be recommended if the basin is converted to complete capture.

Table 12-6. Alternative Evaluation for Provide Flow-paced and TRC-paced Chemical Feed Control System (Project PF-DIS-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Adv.:</i>	Less maintenance. Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires more operator input to monitor disinfection performance. May result in less	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Install Flow-paced and TRC-paced Chemical Feed Control System	Health and Safety	3	3.45	\$ 220,000	\$ 4,860	\$ 322,496	\$ 93,477	Not Applicable
	<i>Definition:</i>	Upgrade chemical feed control system utilizing flow-pacing and TRC-pacing.	Water Quality & Compliance	5						
	<i>Adv.:</i>	Less operator input during a rain event. Better control of chemical feed resulting in more	Capacity Enhancement	3						
	<i>Disadv.:</i>	Maintenance intensive. Flow pacing is common of CSO facilities, but TRC-pacing is difficult	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	2						

12.2.3 Odor Control

12.2.3.1 Description of Existing System

The Puritan-Fenkell odor control system consists of two separate odor control systems. One system treats foul air from the Headworks and pump station wet well area and the other treats foul air from the basins. Each system includes a scrubber tower, recirculation pump, caustic feed system, hypochlorite feed system, and an odor control fan. The original system was designed to feed sodium hydroxide and sodium hypochlorite; however, the sodium hydroxide has not been used for some time. The scrubber tower contains 5.5 ft of plastic media with a chemical spray section located above the media.

The system was installed in 1996. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past 3 years.

12.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack.

Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous. Prior to implementing either one of these options, GLWA could sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water.

12.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs."

12.2.4 Flushing and Dewatering

12.2.4.1 Description of Existing System

Dewatering System: Water from the basin can be dewatered by gravity after a storm event. There are also three dewatering pumps used to dewater the basin. Dewatered flow is conveyed to the NWI.

Flushing System: There are a total of 16 tipping buckets on the side walls of both basin compartments and the influent channels. City water is used to fill the tipping buckets.

Table 12-7 provides an overview of the existing flushing and dewatering system at Puritan-Fenkell CSO facility.

Table 12-7. Overview of Existing Flushing and Dewatering System at Puritan-Fenkell CSO Facility

Parameter	Value
Total Basin Volume (MG)	2.8
Headworks and basin Dewatering and Flushing System	- There are three 3,200-4,500 gpm dewatering pumps 7 tipping buckets for each basin (14 total) 2 tipping buckets in influent distribution channel

12.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- There is no way to achieve positive isolation between the dry weather and wet weather wet wells
- The bearing assemblies for the tipping buckets are inaccessible for periodic inspection
- A number of actuators on the flushing lines have been removed and not replaced
- The dewatering force main from the CSO facility to the NWI is inaccessible but may require future inspection and cleaning
- O&M staff noted that a water spray system is needed near the influent and dewatering pumps to clean the platform and grating around the area

12.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Isolation of Sanitary and Dewatering Wet Well (Project PF-FD-1). The Puritan-Fenkell CSO facility continuously functions as a lift station for dry weather flows using two dry weather submersible pumps. These pumps and associated wet well are fed through a low-flow trough in the influent channel and they are adjacent to the basin dewatering pumps and their associated wet well. Currently, there is no secure way to achieve positive isolation between the dry weather and wet weather wet wells and GLWA O&M staff requested this be provided.

There are two alternatives for this project:

- Alternative 1: Do Nothing.**
- Alternative 2: Wet Well Improvements.** In 2013, Metco prepared a basis of design report, with a figure and cost estimate to provide a new 30-in. by 30-in. stainless steel gate on the influent to the dry weather wet well. See Volume 6 – Appendices, Appendix B, for figures (Figure PF-FD-1-ALT-2) of the proposed layout.

O&M staff noted that a water spray system is needed near the influent and dewatering pumps to clean the platform and grating around the area. An NPW line running from the Control Building to the hypochlorite storage room could be tapped and routed to the catwalk area located below the

Headworks floor. Multiple water cannons could be arranged to adequately clean the area. See Volume 6 – Appendices, Appendix B, for figures (Figure PF-FD-1-ALT-2) for a conceptual layout.

The alternative evaluation for these alternatives is presented in Table 12-8. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.5 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M and component performance provided by the added wet well isolation and spray system. The NPV/Benefit cost for Alternative 2 is \$24,000, which is a relatively low cost compared to other projects recommended in this assessment. As such, **Alternative 2 – Wet Well Improvements is the recommended alternative.**

Access to Tipping Buckets (Project PF-FD-2). O&M staff noted that the bearing assemblies for the tipping buckets are inaccessible; however, they require periodic inspection. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Access to Tipping Buckets for Maintenance.** This alternative consists of constructing manhole openings above each adjoining set of rotating groups. A total of 19 manhole openings are required, including one over each bearing assembly on the end tipping buckets.

The bearing assemblies are located in an unpaved area atop of the basins. Installation requires excavating to the top of the existing roof slab. A 24-in. opening will be cored through the roof, and manhole grade rings set/doweled over the opening and extended to 6 in. above the existing ground surface to prevent runoff intrusion. A standard 24-in. manhole ring and lid will be set and bolted to the grade rings, and the excavation backfilled around the new access point. Final restoration will include lawn seeding.

The costs include extending a 0.5-in. metal grease tube and grease gun fitting from each bearing assembly to within 6 in. of the surface at the nearest new manhole opening (two zerks per manhole, one each at the end tipping buckets). After consultation with the tipping bucket gate manufacturer, regular greasing of the bearings is not required for the model of tipping buckets installed at the Puritan-Fenkell CSO Facility. GLWA may elect to install the access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly. Figures PF-FD-2-ALT-2, included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

Finally, a number of actuators have been removed and not replaced. The replacement of these actuators has been included in the cost estimate.

The alternative evaluation for these alternatives is presented in Table 12-9. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and increased ease of O&M provided by the improved access to the tipping bucket bearings. The NPV/Benefit cost for Alternative 2 is \$27,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 – Provide Access to Tipping Buckets for Maintenance is the recommended alternative.**

Table 12-8. Alternative Evaluation for Wet Well Improvements (Project PF-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not applicable

2	<i>Alt. Name:</i>	Provide Access to Tipping Buckets for Maintenance	Health and Safety	4	3.50	\$ 95,000	\$ -	\$ 95,000	\$ 27,143	Not applicable
	<i>Definition:</i>	Construct 19 manhole openings, including one over each bearing assembly on the end tipping buckets	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Dewatering Force Main (Project PF-FD-3). GLWA noted that the dewatering force main from the CSO facility to the NWI is inaccessible but will require future inspection and cleaning. There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Access to Dewatering Force Main for Inspection and Cleaning.** This alternative consists of the installation of cleanouts at the following locations: 1) at the end of the force main, southwest of the siphon head chamber in Manhole No. 1 for cleaning of the force main, 2) northeast of the Manhole No. 1 before the inverted siphon, and 3) on the east side of the Rouge River, just before Manhole No. 2. (See Figure PF-FD-3-ALT-2 included in Volume 6 – Appendices, Appendix B.)

The alternative evaluation for these alternatives is presented in Table 12-10. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.6 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M and improved component performance provided by the ability to access the force main. The NPV/Benefit cost for Alternative 2 is \$27,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Dewatering Force Main is the recommended alternative.**

Table 12-10. Alternative Evaluation for Access to Dewatering Force Main (Project PF-FD-3)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.68	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Dewatering forcemain from the CSO facility to the NWI remains inaccessible.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Access to Dewatering Force Main for Inspection and Cleaning	Health and Safety	3	3.32	\$ 90,000	\$ -	\$ 90,000	\$ 27,136	Not applicable
	<i>Definition:</i>	Install cleanouts at a number of locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access to the dewatering forcemain from the CSO facility to the NWI for future inspection	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.5 HVAC

12.2.5.1 Description of Existing System

The Puritan-Fenkell CSO facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard. The facility also includes the retention basins. Table 12-11 provides summary of the major equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, emergency shower/eye wash, regular shower, and drinking fountain. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 12.2.10.

Table 12-11. Major HVAC Equipment at Puritan-Fenkell CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-2	Heating and Ventilating Unit	11,100 CFM
	EF-5	Exhaust Fan	10,000 CFM
Basin	SF-1 and 2	2 × Supply Fans (Basin Ventilation)	97,000 CFM
	SF-3	Supply Fan (Shunt Valve Chamber)	2,300 CFM
	SF-4	Supply Fan (Effluent Valve Chamber)	2,300 CFM
	EF-7	Exhaust Fan (Shunt Channel Valve Chamber)	400 CFM
	EF-8	Exhaust Fan (Effluent Valve Chamber)	400 CFM
	UH-1	Unit Heater (Shunt Channel Valve Chamber)	400 CFM 17.0 MBH
	UH-2	Unit Heater (Effluent Valve Chamber)	400 CFM 17.0 MBH
Odor Control Room	HVU-1	Heating Ventilating Unit	4,700 CFM
	EF-5	Exhaust Fan	4,700 CFM
Electrical Room	PACU-1	Heating Ventilating Unit	2,200 CFM

Table 12-12 provides a summary of the basis of design performance criteria for HVAC systems at Puritan-Fenkell and Table 12-13 provides the outdoor Basis of Design conditions.

Table 12-12. Puritan-Fenkell Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Retention Basin	Class I, Group D, Div 1	N/A	N/A	10 ACH
Headworks and Pump Room	Class I, Group D, Div 1	60	N/A	12 ACH
Odor Control Room	Unclassified for areas greater than 3 ft from odor control vessel. Class I, Group D, Div 2 for areas closer than 3 ft.	70	N/A	10 ACH
Electrical Room, Work Room, Office, Toilet, Etc.	Unclassified	70	78	2 cfm/ft ²
Basement (Magnetic Meter Room)	Unclassified	70	N/A	6 ACH

12.2.5.2 Identified Needs and Issues

During the Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- PACU-1 requires replacement.
- HVU-1 in Odor Control Room requires replacement.
- Supply and exhaust fans in Shunt Channel and Effluent Channel require replacement.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- PACU-1 requires constant maintenance to keep running: GLWA's HVAC contractor noted that PACU-1 has had a multitude of problems including damper problems, actuator problems, refrigerant leaks and wiring issues.
- HVU-1 locks out at least once a week.
- HVU-3 is very difficult to service due to location.

During site investigations (June 2020), the following observations were noted:

- PACU-1 was down for repair and GLWA's HVAC contractor staff were working on it on the day the site investigation took place.
- The exhaust fan was off in the Headworks Area

- Improvements are needed for code compliance in the Odor Control and Headworks Areas
- SF-1 and SF-2 were functional but had corroded bases

12.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project PF-HVAC-1). Due to the numerous HVAC-related assets that require replacement in-kind and the additional need to provide monitoring for code compliance in the Odor Control Room and Headworks, all of the identified HVAC improvements are proposed to be in one capital improvement project – HVAC Improvements. As such, there is only one alternative for this project, which includes:

- PACU-1 Replacement
- Improvements to Enhance Safety in Odor Control Area
- Improvements to Enhance Safety in Headworks Area
- HVU-1 and 2 Replacement
- HVU-3 Replacement (with improved access)
- SF-1 and SF-2 Replacement
- Exhaust Fan Replacement
- Removal of Shunt Channel and Effluent Channel HVAC Equipment

Each of the HVAC-related improvements listed above are described further below:

PACU-1 Replacement. Given the age of PACU-1 (24 years), the lengthy history of various issues, and the fact that the unit was undergoing repair the day of site walkthrough, replacement of PACU-1 with a more efficient modern unit and controls is recommended.

Improvements to Enhance Safety in Odor Control Area. The Odor Control area is classified as a Class I, Division 2 space under NFPA 820 if it is not continuously ventilated at a rate of 6 ACH. The space does not meet the 6 ACH ventilation requirement and does not currently have electrical equipment rated for a Class I, Div 2 environment. HVU-1 is designed to provide 10 ACH of ventilation air in cooling mode but was sized to provide only 2 ACH of outside air in heating mode. Additionally, EF-2 is only designed to operate in cooling mode at 10 ACH. NFPA 820 requires both supply and exhaust fans to operate continuously to declassify odor control areas.

Given the age of HVU-1 and EF-2 and the problems HVU-1 is exhibiting, Jacobs recommends replacement of both units. HVU-1 and EF-2 could be replaced with units with two-speed fans or VFDs to provide 6 ACH continuously during ventilation and heating and 10 ACH in cooling mode.

Regardless of whether the space is unclassified by providing 6 ACH of outside air, NFPA 820 requires the installation of combustible gas detection in the Odor Control area with audible and visible alarms at all entrances to the Odor Control area and within the space.

If ventilation is used to declassify the space as described above, ventilation flow monitoring of both the supply and exhaust fan is required with visible and audible alarms of a low or no flow condition required at entrances and within the space.

Improvements to Enhance Safety in Headworks Area. HVU-2 serves the Headworks Area, which is classified as a Class I, Division 1 space per the design drawings. Given its age, and general condition, it should be replaced. Because the electrical equipment in the space is rated for a Class I, Division 1

environment continuous ventilation and ventilation flow monitoring are not required. NFPA 820 does, however, require combustible gas detection with visible and audible alarms at the entrances to the Headworks area and inside the space, which the Headworks area currently does not have. Jacobs recommends making this change to comply with NFPA 820.

HVU-3 Replacement (relocated with improved access). HVU-3 is currently mounted high in the Metering Room in the basement making access for maintenance very difficult (Figure 12-4). Placing HVU-3 lower in the space would make access to the magnetic meter and associated piping very difficult, which is likely the reason the decision to mount the unit high in the space was made. Jacobs recommends replacing HVU-3 with a unit mounted on a concrete pad on the North side of the building when HVU-3 requires replacement. There is an existing opening for the Meter Room supply air duct, which could be utilized by the outdoor unit. This approach would allow ample space for maintenance and would make removal much easier. Currently, HVU-3 will need to be removed in sections when replacement is necessary.

Figure 12-4. HVU-3 Located in Difficult to Access Location Located in Inaccessible Area

SF-1 and SF-2 Replacement. SF-1 and 2 are functional despite having corroded bases (Figure 12-5). These units will require replacement in the near future.

Figure 12-5. Corroded Supply Fan Bases – View from Above (left) and View from Below (right)

Exhaust Fan Replacement. There are five relatively small exhaust fans that are original to the facility and should be included in the replacement project.

Removal of Shunt Channel and Effluent Channel HVAC Equipment. The unit heater, supply and exhaust fans in the Shunt Channel and Effluent Channel are not used and are inoperable. These units could be retired. Portable ventilation could be utilized, if necessary, when operators need to enter these areas.

The alternative evaluation is presented in Table 12-14. **The capital cost for Alternative 1, which is the recommended alternative,** is included in Volume 6 – Appendices, Appendix C under this project title.

Table 12-14. Alternative Evaluation for HVAC Improvements (Project PF-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	3	3.00	\$ 810,000	\$ -	\$ 810,000	\$ 270,000	Best Value Alternative
	<i>Definition:</i>	Facility-wide HVAC Improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, less emergency maintenance, improved asset reliability.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.6 Electrical

12.2.6.1 Description of Existing System

The Puritan-Fenkell electrical system consists of one DTE utility feed from a 750 kVA, 480/277 V, 3-Phase outdoor transformer (secondary metering) and diesel generator feed from a 400 kW, 480/277 V, 3-Phase stationary generator. The feeds are connected to a 1,200 A MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP has breakers that feed MCCs and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 12-15 provides a summary of the major electrical equipment for this facility.

Table 12-15. Major Electrical Equipment at Puritan-Fenkell

Location	Major Electrical Equipment	Description
Electrical Room	Main distribution panel with ATS	1,200 A, 480/277 V, 3-Phase
Courtyard	Generator (Diesel)	400 kW, 480/277 V, 3-Phase
Electrical Room	MCC-1	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	600 A, 480/277 V, 3-Phase

12.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the following section.

12.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project PF-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure PF-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Wet Well Chamber Area – Add LED lighting fixtures within the area to address the required foot-candles and code requirements.
 - Effluent channel – Add interior LED ceiling and wall mounted lighting fixtures within the area to address the required foot-candles and code requirements.
 - Basin – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the Basins. Lighting to meet the required foot-candles and codes for the area.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including receptacles every 100 ft on the backside exterior of the facility at ground level.

The alternative evaluation is presented in Table 12-16. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$59,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 12-16. Alternative Evaluation for Electrical Improvements (Project PF-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe due to poorer lighting at night	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 205,000	\$ -	\$ 205,000	\$ 58,571	Not applicable
	<i>Definition:</i>	Add additional lighting in wet well chamber area, effluent channel, and basins. Provide exterior power receptacles.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

12.2.7 I&C

12.2.7.1 Description of Existing System

Control System: The original Allen Bradley control system was installed in 1996 under PC-697. Since then, several modifications to the original system have taken place. These upgrades provided the ability to locally and remotely monitor the operations of the facility and the overall collection system, including from the SCC. The control system and workstation software are Allen Bradley PLC-5 redundant PLCs with Rockwell RSView software. The existing hardwired backup control panel and other miscellaneous PLCs and subsystems were also incorporated into the overall control system. The current PLC-5 control system, workstations and backup panels are obsolete, and do not meet GLWA SCADA Governance standards, which stipulate that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a backup radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 12-17 summarizes the level sensors and flow meters at the Puritan-Fenkell CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 12-17. Summary of Flow Meters and Level Sensors at Puritan-Fenkell CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent (Storm sewer)	1	Transit-Time (AccuSonic)
Shunt Channel	1	Transit-Time (AccuSonic)
Effluent Overflow Weir	2	Ultrasonic ^a
Basin Dewatering	1	Magnetic
CSO Level Sensors		
Influent (Storm Sewer)	1	Ultrasonic
Shunt Channel	1	Ultrasonic
Screening Area (Upstream and downstream of bar racks)	2	Ultrasonic
Basins	2	Ultrasonic
Wet Well	1	Ultrasonic
	1	Radar
Effluent	1	Ultrasonic
River	1	Ultrasonic
Chemical System Flow Meters		
Process Water	1	Magnetic
Chemical Feed	1	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Pressure

^a Ultrasonic level sensor readings are used to measure height of water to allow calculation of effluent flow rate.

12.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Need for tank level indication at Chemical Fill Station
- Need for process cameras at select locations
- Update Ovation control system

12.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

I&C Improvements (Project PF-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the Ovation Control System Upgrade, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: I&C Improvements** including,

- Provide tank level indication at Chemical Fill Station
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Provide tank level indication at Chemical Fill Station. Tank level indication is described and recommended in Section 5.4.5.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 12-18. The sources of costs used in this evaluation are listed below:

- The O&M costs for Alternative 2 include estimated annual maintenance costs for the additional instrumentation provided.
- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 – I&C Improvements, has a total benefit score about 0.3 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and ease of O&M provided by the various I&C improvements. The NPV/Benefit cost for Alternative 2 is \$53,000, which is a relatively lost cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – I&C Improvements is the recommended alternative.**

Table 12-18. Alternative Evaluation for I&C Improvements (Project PF-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	3.00	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Known existing system.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Performance isn't met with regards to safety and compliance - flows and volumes, alarms, disinfection, system status, etc.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 70,000	\$ 5,000	\$ 175,448	\$ 52,899	Not applicable
	<i>Definition:</i>	Install tank level indication and process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Higher performance, improved safety, improved compliance control, more efficient operations.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased complexity and higher maintenance.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

Control System Upgrade (Project PF-I&C-2). The current facility's PLC control system, network, workstations and control system backup panels are obsolete and should be replaced in the near future. The control system does not meet GLWA SCADA Governance standards, which require that all CSO facilities use Ovation workstations with new high-performance graphics. GLWA's standards for local CSO facility's control systems can be either the latest Allen Bradley PLC system with Ovation workstations or a complete Ovation system. This approach is being used on an ongoing project at Leib, Seven Mile, and St. Aubin.

Because of the approach used on the ongoing project, there is only one overall control system alternative considered. The project should include decommissioning and removal of the original hardwired backup local control panels. These local panels are no longer required with today's redundant control system processors and local Operator Interface Terminal (OIT) as local backup to the facility's workstations.

Table 12-19 provides the summary of the **Control System Upgrade, which is the recommended alternative**. Capital costs are included in Volume 6 – Appendices, Appendix C under this project title. Consideration should be given to replacing various field instruments during this project; however, these are not included in the capital costs.

Table 12-19. Alternative Evaluation for Control System Upgrade (Project PF-I&C-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Control System Upgrade	Health and Safety	3	3.00	\$ 2,323,000	\$ -	\$ 2,323,000	\$ 774,333	Best Value Alternative
	<i>Definition:</i>	Install current technology, higher performing control system hardware and software that is standardized across all CSO facilities. Ovation is the recommended system.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved performance, standardized HMI screens, can have standardized redundant "on-the-shelf" parts.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No performance related disadvantages.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.8 Site

12.2.8.1 Description of Existing Site

Access to the site is off of Five Mile Road through a 25-ft wide swing gate. Site security is provided by a perimeter fence comprised of an 8-ft chain-link fence. The parking lot consists of 4-in. thick asphalt pavement with 8-in. gravel base. Sidewalks are 5 ft wide and consist of 4 in. of concrete with a 4-in. sand base. Site utilities include watermain, gas, sanitary and electric.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

12.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- Removal and installation of effluent stop logs is difficult.
- Rain gutters and downspouts are not installed, causing roof runoff to pond around the sidewalk, creating a safety issue for personnel accessing the building.
- Entrance Gate. The existing entrance security gate at the site is a 25-ft wide swing gate. This gate has been experiencing recurring maintenance issues recently and has reached the end of its useful service life. The gate should be replaced with a rolling gate.
- Repair cracks in asphalt parking lot surface.

The following issues were addressed under "*GLWA-CON-1902040 Site Improvements at P-F Detention Facility and Leib Screening and Disinfection Facility*" Contract and are not included in the capital improvement projects for CS-299.

- Extend Security Fence. The existing security fencing only extends around three sides of the Control Headworks Building and Basin. The river side of the site is not fenced.
- Address Drainage on Basin. The overburden cover on top of the basin roof is poorly drained and typically remains saturated for several days following a rain event. Service trucks with equipment have trouble navigating the basin roof while the soil is saturated.

12.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Stop Log Removal System for Effluent Gates (Project PF-Site-1). Removal and installation of stop logs is difficult. There are two alternatives for this project:

1) **Alternative 1: Do Nothing.**

- 2) **Alternative 2: Stop Log Removal System for Effluent Gates.** A davit arm crane is recommended at the three hatch openings of the effluent gates and stop logs to assist in removal of hatch covers, the installation and removal of stop logs and other equipment from the effluent butterfly gate vault. A small area in the vicinity is recommended to be paved with concrete for temporary storage of stop logs.

Additionally, construction of a service road would assist access to the effluent gate vault site. Because the Puritan-Fenkell facility is located in a City park, the appearance of the service drive must blend in with the grass covered surroundings. It is recommended that the installed service road consist of an engineered fill base that will support a grass paver surface that will eventually support vegetation growth to better blend in with the natural surroundings, while giving vehicles access to the effluent gates. The service drive will extend from the existing Eliza Howell office parking lot and will be about 16 ft wide and approximately 265 ft long. Since this is in City park, it will likely require an easement. See Figure PF-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, for the conceptual layout.

The alternative evaluation is presented in Table 12-20. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$75,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – Stop Log Removal System for Effluent Gates, is the recommended alternative.**

Table 12-20. Alternative Evaluation for Stop Log Removal System for Effluent Gates (Project PF-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Removal and installation of stop logs is difficult.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Stop Logs Removal System for Effluent Gates	Health and Safety	3	3.22	\$ 240,000	\$ -	\$ 240,000	\$ 74,611	Not applicable
	<i>Definition:</i>	A davit arm crane is recommended at the three hatch openings of the effluent gates and stop logs to assist in removal of hatch covers, the installation and removal of stop logs and other equipment from the effluent butterfly gate vault.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Ease of removal and installation of stop logs.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

General Site Improvements (Project PF-SITE-2). The roof on the Puritan-Fenkell Control and Headworks Buildings was recently replaced. However, rain gutters and downspouts were not installed. Roof runoff currently runs to the front of the Control Building and drops to grade where it tends to pond around the sidewalk, creating icy conditions during the winter and a safety issue for personnel accessing the building.

The Courtyard in the Headworks area has an open roof and is exposed to rain and snow falling on its floor surface. There are scuppers in the base of the south wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface.

This project also includes replacement of the entrance gate and restoration of the pavement.

There are two alternatives to address these issues:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: General Site Improvements:** It is recommended that a rain gutter and downspouts be added to the Control and Headworks Buildings to capture roof runoff and funnel it away from the building at grade. The Courtyard in the Headworks area has an open roof and is exposed to rain and snow falling on its floor surface. There are scuppers in the base of the south wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface. To alleviate the water ponding on the Courtyard floor, it is recommended that holes be cored through the courtyard floor to the basin below. Recessed area drains can be installed in the cored holes to funnel floor drainage to the basin.

This alternative also includes replacement of the entrance gate and restoration of the pavement.

The alternative evaluation is presented in Table 12-21. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.7 higher than the Do Nothing Alternative (Alternative 1) based on the improved O&M. The NPV/Benefit cost for Alternative 2 is \$34,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved O&M with this alternative, Alternative 2 – General Site Improvements, is the recommended alternative.**

Table 12-21. Alternative Evaluation for General Site Improvements (Project PF-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative

	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety concern related to ponding water and security issue with non-functioning gate	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	General site Improvements	Health and Safety	4	3.28	\$ 112,000	\$ -	\$ 112,000	\$ 34,112	Not applicable
	<i>Definition:</i>	Install rain gutter and downspouts; repair pavement	Water Quality & Compliance	3						
	<i>Adv.:</i>	Safety concern with ponding is eliminated	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.9 Architectural

12.2.9.1 Description of Existing Facilities

The Puritan-Fenkell CSO facility consists of chemical room, utility support (electrical), control room, odor control room, screen room, miscellaneous other rooms and a courtyard. The facility also includes retention basins.

12.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment, as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the ongoing Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff raised the following issues:

- It was identified that the existing basin access is through a 4 ft by 6 ft hatch with temporary wooden stairs and these stairs are not code-compliant.
- There is no access to the Headworks area and the Courtyard during a power outage.

These two issues are being addressed in an ongoing project under a JOC.

12.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (PF-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) **Alternative 1: Do Nothing.**

2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints

- Remove and replace isolation/ cove joint sealant and around building perimeter
- Remove and replace cracked façade limestone panels
- Replace damaged/stained/missing acoustic ceiling tiles in Control Building
- Address door hardware issues
- Clean, prepare surface and coat stained CMU walls in the Headworks

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure PF-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 12-22. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 12-22. Alternative Evaluation for Architectural Rehabilitation (Project PF-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 351,000	\$ -	\$ 351,000	\$ 113,226	Not applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.10 Safety

12.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

12.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 12-23. The capital improvement project to address these issues is included in the table.

Table 12-23. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Odor Control Room	No tempering valve on eyewash/shower	Provide tempering valve	Safety Improvements (Project PF-SAFE-1)
Chemical Room	Emergency eyewash/shower outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project PF-SAFE-1)
Chemical Room	Emergency eyewash/shower 0943390 outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project PF-SAFE-1)
Basement stairwell	No illuminated exit signs	Add exit signs	Exit Sign Improvements ^a
Headworks	Illuminated exit signs not working	Replace exit signs	Exit Sign Improvements ^a
Utility tunnel	Illuminated exit signs not present	Add exit signs	Exit Sign Improvements ^a
Utility Tunnel Access	Illuminated exit signs are out. Exit signs missing in locations.	Add or replace exit signs.	Exit Sign Improvements ^a
Utility Tunnel	Ladder at end of tunnel has an exit sign but hatch is locked.	Add placard to fixed ladder "Not An Exit." Replace existing exit sign with directional exit sign away from ladder access.	Exit Sign Improvements ^a
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project PF-SAFE-1)

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

12.2.10.3 Description and Evaluation of Needs and Issues

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project PF-SAFE-1). This project should address the safety issues identified above. These issues include:

- Provide tempering valve on eyewash/shower in the Odor Control Room
- Add eyewash/shower outside containment in the Chemical Room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 12-24 shows the one alternative.

Table 12-24. Alternative Evaluation for Safety Improvements (Project PF-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 126,000	\$ -	\$ 126,000	\$ 42,000	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

12.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Puritan-Fenkell CSO Facility.

12.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Puritan-Fenkell CSO facility, Table 12-25 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 12-25, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 12-25. Listing of Asset Condition Assessments for Puritan-Fenkell Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Three inactive pumps are listed in WAM - Basin 1 Sample Pump, Basin 2 Sample Pump, and Shunt Channel Sample Pump. These pumps are being considered for removal from WAM.

^d The Shunt Sampler 1 is listed in WAM. This sampler is being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Puritan-Fenkell Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

12.3 Capital Planning for Puritan-Fenkell CSO Facility

12.3.1 Summary of Capital Improvement Plan Projects

Table 12-26 provides a summary of the recommended CIP projects and associated capital costs for the Puritan-Fenkell CSO facility based on the alternative evaluations conducted for this facility.

Table 12-26. Summary of Recommended Projects at Puritan-Fenkell CSO Facility

Project No.	Alternative	Description	Total Project Cost
PF-WWMP-1	2	Convert to Complete Capture Basin	\$ 2,600,000
PF-SCR-1	2	Screening Improvements	\$ 230,000
PF-DIS-1	3	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 383,000
PF-DIS-2	2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
PF-FD-1	2	Wet Well Improvements	\$ 79,000
PF-FD-2	2	Provide Access to Tipping Buckets for Maintenance	\$ 95,000
PF-FD-3	2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
PF-HVAC-1	1	HVAC Improvements	\$ 810,000
PF-ELEC-1	2	Electrical Improvements	\$ 205,000
PF-I&C-1	2	I&C Improvements	\$ 70,000
PF-I&C-2	1	Control System Upgrade	\$ 2,323,000
PF-SITE-1	2	Stop Log Removal System for Effluent Gates	\$ 240,000
PF-SITE-2	2	General Site Improvements	\$ 112,000
PF-ARCH-1	2	Architectural Rehabilitation	\$ 351,000
PF-SAFE-1	1	Safety Improvements	\$ 126,000

12.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 12-27. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 12-27. Capital Improvement Plan Projects for Puritan-Fenkell CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
PF-1 Convert to Complete Capture Basin	\$ 2,600,000	2030 <i>Timing based on general CSO project priorities</i>	PF-WWMP-1	Convert to Complete Capture Basin	\$ 2,600,000
PF-2 Disinfection System Improvements	\$ 603,000	2032 <i>Timing based on asset condition</i>	PF-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	\$ 383,000
			PF-DIS-2	Install Flow-paced and TRC-paced Chemical Feed Control System	\$ 220,000
PF-3 Flushing System Improvements	\$ 616,000	2032 <i>Timing based on best judgement</i>	PF-FD-1	Wet Well Improvements	\$ 79,000
			PF-FD-2	Provide Access to Tipping Buckets for Maintenance	\$ 95,000
			PF-FD-3	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
			PF-SITE-1	Stop Log Removal System for Effluent Gates	\$ 240,000
			PF-SITE-2	General Site Improvements	\$ 112,000
PF-4 HVAC Improvements	\$ 810,000	2027 <i>Timing based on asset condition</i>	PF-HVAC-1	HVAC Improvements	\$ 810,000
PF-5 Facility-Wide Electrical and I&C Improvements	\$ 2,598,000	2029 <i>Timing based on asset condition</i>	PF-ELEC-1	Electrical Improvements	\$ 205,000
			PF-I&C-1	I&C Improvements	\$ 70,000
			PF-I&C-2	Control System Upgrade	\$ 2,323,000
PF-6 Facility-Wide Safety and Architectural Improvements	\$ 477,000	2023 <i>Project should be initiated as soon as possible</i>	PF-ARCH-1	Architectural Rehabilitation	\$ 351,000
			PF-SAFE-1	Safety Improvements	\$ 126,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 12-28 and Table 12-29 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 12-29 indicates that PF-DIS-1 project has one asset that needs to be replaced immediately due to condition score of "5". This asset, however, has already been replaced/rebuilt since the Condition Assessment was conducted in Summer 2020. The remaining nine assets that are included in this project have an average condition score of 1.27 and an average replacement date of 2032 (See Table 12-28). This information was used to propose a scheduled construction completion date of 2032.

Table 12-28. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
PF-DIS-1	9	1.67	1.27	2.75	12	2032	\$ 311,400
PF-HVAC-1	10	1.19	1.47	2.06	20	2039	\$ 306,011
PF-I&C-2	2	2.29	1.57	4.08	12	2029	\$ 1,397,075
PF-SCR-1	1	1.43	1.89	2.78	20	2034	\$ 146,071

Table 12-29. Information for Assets with Condition 5 in Capital Improvement Projects

12.3.3 20-Year Capital Outlay Plan

Table 12-30 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 12-30. 20-Year Capital Outlay Plan for Puritan-Fenkell CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ 142,700	\$ -	\$ -	\$ -	\$ 29,000	\$ -	\$ -	\$ 113,700	\$ -	\$ -	\$ -	\$ -	\$ -

Total	\$ 8,527,553	\$ 222,386	\$ 230,654	\$ 2,072,341	\$ 363,445	\$ 574,337	\$ 256,664	\$ 623,437	\$ 2,227,376	\$ 1,769,773	\$ 129,839	\$ 29,886	\$ 27,416

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Two influent slide gate (SG-1 and SG-5; \$157,000 each) received a score of 5 since they were locked out of service at the time of the Condition Assessment.
- HVAC System: One AHU (HV-1, \$63,500) was out of service at the time of inspection. Two electric unit heaters (\$19,500 each) , two supply fans (SF-3 and SF-4; \$3,000 each), and two exhaust fans (EF-7 and EF-8; \$2,600 each) received a score of 5 due to severe corrosion on the units and have been out of service for some time.

13. Seven Mile CSO Control Facility

13.1 General Facility Description and Future Capacity Considerations

13.1.1 General Facility Description

The Seven Mile CSO Facility is an RTB with 2.2 MG of storage and a treatment capacity of 655 cfs through the treatment system. It was constructed in 1997. Since it was constructed, the facility has rarely discharged, with one recorded event of 490,000 gallons of discharge in 2014 from a nearly 6-in. rain event. For this reason, Section 13.1.2 describes potential modifications to make this facility into a "Capture-Only" facility. A similar recommendation is made for the Puritan-Fenkell CSO Facility.

The facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

13.1.2 Modifications to Make Seven Mile Facility into a Capture-Only Facility (SM-WWPM-1)

The WWMP recognized that "GLWA has developed a protocol to operate the Puritan-Fenkell and Seven Mile basins in capture-only mode (no treatment or discharge) for flows up to the 10-year 1-hour design storm. This finding provides a significant water quality benefit because the 1,114-acre service area can be captured, stored, and returned to the WRRF following a storm event preventing release of an estimated 700 million gallons of combined sewer overflow each year."

Operating these two facilities in capture mode would allow for the cost avoidance of operating and maintaining the hypochlorite feed and storage systems, and it would likely not require operations labor to be onsite during a storm event.

Wade Trim conducted a study ("Puritan-Fenkell and Seven Mile CSO Retention and Treatment Basins Basin Collection System and Hydraulic Analysis", dated August 29, 2019). This hydraulic study included an analysis "to evaluate the potential of operating the basins in capture-only mode as a possible operational protocol for the system. Capture basin operation was evaluated to understand the impacts on untreated overflow from the 17 Main Rouge River outfalls on the Detroit West Side system, flooding impacts of the utility tunnels within the two basins, and the risk of upstream basement flooding."

The findings of the study included:

- Limited (approximately 2 percent) increase in untreated overflow from the 17 Main Rouge River outfalls as a result of capture mode operation.
- Impact to the utility tunnels when operating in capture mode is expected for design storms between the 10-year, 24-hour and the 25-year, 24-hour storm at the Puritan-Fenkell basin. At the Seven Mile basin, design storms slightly smaller than the 10-year, 24-hour storm will begin to impact the utility tunnel.
- The evaluation of basement flooding risk shows the basins can be operated in capture mode for the 10-year, 24-hour storm without risk of basement flooding. However, during the 25-year, 24-hour storm significant basement flooding can be expected.

The report concluded that operating the basins in capture-only mode in their current configuration is not recommended due to the risk of basement flooding. The report indicated, however, that capture-only

mode may be possible if high level emergency overflows are added to the basins to relieve the system during extreme events to protect basements from flooding.

To aid in the analysis of operating both Puritan-Fenkell and Seven Mile as capture-only basins, conceptual cost estimates have been generated under CS-299 for both facilities including capital improvements listed below. The Wade Trim hydraulic study provided some details regarding these issues, which are included in the description of the conceptual cost estimate; however, additional study and design will be needed.

- 1) Emergency overflow relief. The current weir wall is about 12 ft high at both facilities. A new weir wall about 20 ft high and associated structural modifications are needed at the effluent end of the basin to construct a taller weir wall. The length of weir was not reported and should be included in the future study.
- 2) Utility tunnel flooding protection. Water-tight doors are recommended where there is access to the basin from the utility tunnel and at the influent end of the utility tunnel. The proposed doors can withstand 20 ft of static head.
- 3) Replace the existing effluent butterfly gates with flap gates. The Wade Trim report evaluated two different locations for these gates at each facility, which would prevent backflow into the facility (see Figure 13-1 below showing one of the locations, which was used for the cost estimate). Additional study should be performed to determine if these flap gates are still needed with the taller proposed weir wall.

Figure 13-1. Potential Options for Flap Gate Retrofit – Seven Mile (from Wade Trim report)

A preliminary life-cycle comparison is presented in Table 13-1. Alternative 1 represents the scenario where the facility continues to operate as an RTB. Alternative 2 represents a scenario where the facility operates in the complete capture mode. The intent of this comparison is to present the cost of the emergency overflow weirs and flap gates compared to the avoided costs associated with maintaining the disinfection system and flow meters for the flow-through treatment mode of operation. The following costs are used in this evaluation:

- The period of evaluation is assumed to be 50 years, which represents an approximate remaining life of the basin.
- For Alternative 1, the capital costs were obtained from the SRP replacement costs and include the chemical feed pumps, drives, piping, and storage tanks. It also includes the flow meters for the

effluent and shunt channel. It is assumed for this analysis that all of these assets would be replaced twice during the period of evaluation.

- For Alternative 1, the O&M costs include those items that are currently needed, but would no longer be needed under a complete capture mode. These costs include Operations labor before and during storm events to make the facility ready for discharge, if necessary (assumed to be 8 storm events per year and 10 hours per storm event). Costs also include hypochlorite usage or degradation of one tank (2,400 gallons) every six months at a unit cost of \$0.90 per gallon.
- For Alternative 2, the total project cost for the modifications described for the emergency weirs and flap gates is provided in Volume 6 – Appendices, Appendix C, under SM-WWMP-1. The costs also include Permitting and Modeling to demonstrate and coordinate the modifications with Michigan EGLE (assumed to be \$100,000).

As shown in Table 13-1, the Best Value Alternative is Alternative 2 – Convert to Complete Capture Basin. As such, it is recommended that this alternative be pursued through additional modeling to confirm water levels in the collection system during peak storm events and coordination with Michigan EGLE.

Table 13-1. Alternative Evaluation for Seven Mile to Convert to Complete Capture Basin

Alt.	Description			Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.		Health and Safety	2	2.50	\$ 2,531,000	\$ 12,320	\$ 3,232,823	\$ 1,293,129	
	<i>Definition:</i>	Do nothing. Continue to operate as an RTB		Water Quality & Compliance	3						
	<i>Adv.:</i>	Known system; no new regulatory issues		Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher level of operator attention during storm events. Must maintain hypochlorite storage and feed system.		Component Performance	3						
	<i>Comments:</i>	None		O&M Ease	2						
2	<i>Alt. Name:</i>	Convert to Complete Capture Basin		Health and Safety	4	3.72	\$ 2,500,000	\$ -	\$ 2,500,000	\$ 672,646	Best Value Alternative
	<i>Definition:</i>	Convert to Complete Capture Basin		Water Quality & Compliance	3						
	<i>Adv.:</i>	Less operator attention during storm events. No O&M for hypochlorite system.		Capacity Enhancement	3						
	<i>Disadv.:</i>	Requires regulatory approval; Modeling confirmation of acceptability		Component Performance	3						
	<i>Comments:</i>	None		O&M Ease	5						

13.2 Facility Assessment

13.2.1 Screening

13.2.1.1 Description of Existing System

The Seven Mile CSO Facility has two bar screens that were installed in 1997. Influent wastewater enters the facility from the Seven Mile Sewer and is routed through the screens to the basin compartments. Material collected by the screens is mechanically raked from the bar screens and deposited into individual dumpsters to be hauled to a landfill.

It should be noted that this facility is planned to become a complete capture facility with emergency overflow to prevent basement flooding based on the recommendations from the WWMP. It is recommended that the screens remain at the facility to prevent large debris from entering the facility.

Table 13-2 provides an overview of the existing screening system at Seven Mile CSO facility.

Table 13-2. Overview of Existing Screening System at Seven Mile CSO Facility

Parameter	Value
Treatment Capacity (cfs)	655
No. of Screens	2
Manufacturer	E & I Corporation
Screen Type	Catenary Bar Screen
Opening Size	0.5-in. spacing
Depth or Length / Width	23 ft 0 in. /9 ft 6 in.
Screen Cleaning	Mechanical Rake
Screening Removal	Conveyor belt to dumpster and landfilled

13.2.1.2 Identified Needs and Issues

There were no needs identified by GLWA or the Jacobs team.

13.2.1.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no screening-related issues that that would be classified as capital improvement "needs."

13.2.2 Disinfection

13.2.2.1 Description of Existing System

This facility was constructed in 1996 and has rarely discharged. Recent studies have been conducted under the WWMP recommending that this basin be modified from a treatment basin to a complete capture basin. Under this scenario, the disinfection system would not be used. As such, it is recommended that the disinfection system be removed or moth-balled at this site.

Table 13-3 provides an overview of the existing disinfection system at Seven Mile CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 13-3. Overview of Existing Disinfection System at Seven Mile CSO Facility

Parameter	Value
Treatment Capacity (cfs)	655
Design Feed Strength (% hypochlorite)	5
Max. Dosage at Design Flow (mg/L Cl ₂)	10 @ 655 cfs
Disinfection Contact Time (min)	30
Storage Tanks Number Volume of Each Tank (gal) Type	2 2,400 FRP
Pumps Number Capacity (gpm) Type	4 20 Gear
Mixers Number / Type Model Number/ hp / Manufacturer	1 / Chemical induction mixers Series 32 / 10 hp / Gas Mastrrr

13.2.2.2 Identified Needs and Issues

The disinfection system should ultimately be demolished and removed from this facility. This includes the chemical storage tanks, chemical feed pumps, piping and associated electrical and instrumentation components. These costs are included in the conversion to a complete capture basin.

13.2.2.3 Description and Evaluation of Alternatives

There were no disinfection-related issues identified by the GLWA or the Jacobs team that would be classified as capital improvements “needs”.

13.2.3 Odor Control

13.2.3.1 Description of Existing System

The Seven Mile odor control system consists of one cross-current vertical scrubber vessel that treats air from the Headworks area and basins. The system includes a scrubber tower, recirculation pump, caustic addition system, sodium hypochlorite addition system and an odor control fan. The scrubber tower contains 5.5 ft of plastic media with a chemical spray section located above the media. The original system was designed to feed sodium hydroxide and sodium hypochlorite; however, the sodium hydroxide has not been used for some time.

The system was installed in 1997. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past three years.

13.2.3.2 Identified Needs and Issues

During meetings with O&M staff related to the odor control system, no needs were identified. The recommendation in this section is based on Jacobs evaluation of the existing system.

Potential Reduction of Odor Treatment during Operation. The facility does not have an air permit and is not required to operate the odor control system. The facility may not generate significant odors during wet weather events due to dilution of sewage with storm water. Storm water significantly reduces the concentration of sulfide and other odorous compounds in sewage. Odors may be more prevalent during the dewatering phase caused by odors from settled solids but may still be low. Due to the expected low odors from the facility, GLWA may want to consider operating the scrubber systems with water only and no sodium hypochlorite. Removal of H_2S is dependent on the H_2S concentration. Removal will be significantly less with only water, but there may be relatively low levels of H_2S to remove. Another option, which provides even less treatment, would be to operate the system without water and blow air through an empty scrubber system and out the stack.

Under both of these options, the discharged air may be non-odorous or sufficiently diluted with ambient air to render it non-odorous. Prior to implementing either one of these options, GLWA could sample influent air to the existing scrubber system for H_2S to determine if the H_2S concentration is sufficiently low. A non-detectable concentration of H_2S in the influent air means the systems can likely operate without sodium hypochlorite or water.

13.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement “needs”.

13.2.4 Flushing and Dewatering

13.2.4.1 Description of Existing System

Dewatering System: There are three dewatering pumps and one sump pump used to dewater the basin after a storm event. Dewatered flow is pumped to the NWI.

Flushing System: There are 14 tipping buckets on the side walls of both basin compartments and the influent channels. City water is used to fill the tipping buckets.

Table 13-4 provides an overview of the existing flushing and dewatering system at Seven Mile CSO facility.

Table 13-4. Overview of Existing Flushing and Dewatering System at Seven Mile CSO Facility

Parameter	Value
Total Basin Volume (MG)	2.2
Headworks and basin Dewatering and Flushing System	- There are three 2,000 gpm dewatering pumps 6 tipping buckets for each basin (12 total) 2 tipping buckets in influent distribution channel

13.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Provide access to tipping buckets for inspection
- Provide access to dewatering force main for inspection and cleaning

13.2.4.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Access to Tipping Buckets (Project SM-FD-1). O&M staff noted that the bearing assemblies for the tipping buckets are inaccessible; however, they require periodic inspection and greasing.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Provide Access to Tipping Buckets for Maintenance.** This alternative provides access for visual inspection of the tipping bucket bearing assemblies consists of constructing manhole openings above each adjoining set of rotating groups. A total of 17 manhole openings would be required, including one over each bearing assembly on the end tipping buckets.

Installation will require removing pavement and excavating to the top of the existing roof slab. A 24-in. opening will be cored through the roof, and manhole grade rings set/doweled over the opening and extended to the existing surface. A standard 24-in. manhole ring and lid will be set flush with the pavement, and the excavation backfilled around the new access point. Final restoration will include pavement repairs and patching to the concrete parking area.

The costs include extending a 0.5-in. metal grease tube and grease gun fitting from each bearing assembly to within 6 in. of the surface at the nearest new manhole opening (2 zerks per manhole, 1 each at the end tipping buckets). After consultation with the tipping bucket gate manufacturer, regular greasing of the bearings is not required for the model of tipping buckets installed at the Seven Mile CSO Facility. GLWA may elect to install the access for better visual confirmation of tipping bucket condition and operation and better access to limit switches at each bearing assembly. Figures (Figure SM-FD-1-ALT-2) included in Volume 6 – Appendices, Appendix B, show the conceptual layout of this improvement.

The alternative evaluation for these alternatives is presented in Table 13-5. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and increased ease of O&M provided by the improved access to the tipping bucket bearings. The NPV/Benefit cost for Alternative 2 is \$36,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Tipping Buckets is the recommended alternative.**

Table 13-5. Alternative Evaluation for Access to Tipping Buckets (Project SM-FD-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Inaccessible bearing assemblies for the tipping buckets	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Access to Tipping Buckets for Maintenance	Health and Safety	4	3.50	\$ 125,000	\$ -	\$ 125,000	\$ 35,714	Not Applicable
	<i>Definition:</i>	Construct manhole openings over each bearing assembly of tipping buckets	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access for better visual confirmation of tipping bucket condition and operation and better	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

Access to Dewatering Force Main (Project SM-FD-2). GLWA noted that the force main from the CSO facility to the NWI is inaccessible but will require future inspection and cleaning.

There are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Access to Dewatering Force Main for Inspection and Cleaning.** this alternative consists of the installation of cleanouts at the following locations: 1) at the end of the force main, southwest of the siphon head chamber in Manhole No. 1 for cleaning of the force main, 2) just to the northeast of the Manhole No. 1 before the inverted siphon, and 3) east side of the Rouge River, just before Manhole No. 2. (see Figure SM-FD-2-ALT-2 included in Volume 6 – Appendices, Appendix B)

The alternative evaluation for these alternatives is presented in Table 13-6. The capital cost for Alternative 2 is included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.4 higher than the Do Nothing Alternative (Alternative 1) based on the increased ease of O&M provided by the ability to access the force main. The NPV/Benefit cost for Alternative 2 is \$28,000, which is a relatively low cost compared to other projects recommended in this assessment. **As such, Alternative 2 –Access to Dewatering Force Main is the recommended alternative.**

Table 13-6. Alternative Evaluation for Access to Dewatering Force Main (Project SM-FD-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Dewatering forcemain from the CSO facility to the NWI remains inaccessible.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Provide Access to Dewatering Force Main for Inspection and Cleaning	Health and Safety	3	3.22	\$ 90,000	\$ -	\$ 90,000	\$ 27,979	Not Applicable
	<i>Definition:</i>	Install cleanouts at a number of locations.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Access to the dewatering forcemain from the CSO facility to the NWI for future inspection and cleaning.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.5 HVAC

13.2.5.1 Description of Existing System

The Seven Mile CSO facility consists of a headworks area, chemical room, odor control room, electrical room, control room, metering room in the basement, and miscellaneous other rooms and a courtyard. The facility also includes the retention basins. Table 13-7 provides summary of the major HVAC equipment for the facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, multiple emergency shower/eye wash, regular shower, and sump pump. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 13.2.10.

Table 13-7. Major HVAC Equipment at Seven Mile CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	HVU-2	Heating and Ventilating Unit	12,190 CFM
	EF-5	Exhaust Fan	11,480 CFM (Pump Area)
Basin	SF-1 and 2	Supply Fan (for Basin)	102,420 CFM
	SF-3	Supply Fan (Utility Tunnel)	1,472 CFM
	SF-4	Supply Fan (Shunt Channel)	2,600 CFM
	EF-7	Exhaust Fan (Shunt Channel)	500 CFM
	EF-8	Exhaust Fan (Effluent Channel)	500 CFM
	UH-1 and 2	Unit Heater (Shunt Chamber)	400 CFM 17.0 MBH
Odor Control Room	HVU-1	Heating and Ventilating Unit	2,400 CFM 65 MBH
	EF-6	Exhaust Fan	2,000 CFM
Basement (Meter Vault)	HVU-3	Heating Ventilation Unit	1,200 cfm
Electrical Room	PACU-1	Packaged Air Conditioning Unit	2,200 CFM 51.2 MBH

Table 13-8 provides a summary of the basis of design performance criteria for HVAC systems at Seven Mile and Table 13-9 provides the outdoor Basis of Design conditions.

Table 13-8. Seven Mile Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Retention Basin	Class I, Div 1, Group D	N/A	N/A	10 ACH
Headworks and Pump Room	Class I, Div 1, Group D	60	N/A	12 ACH
Odor Control Room	Unclassified for areas greater than 3 ft from odor control vessel. Class I, Div 2, Group D	70	N/A	10 ACH

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
	for areas closer than 3 ft.			
Electrical Room, Work Room, Office, Toilet	Unclassified	70	78	2 cfm/ft ²
Basement (Magnetic Meter Room)	Unclassified	70	N/A	6 ACH
NaOCl Storage Room	Unclassified	60	N/A	6 ACH

Table 13-9. Seven Mile Original Outdoor Basis of Design Conditions

Outdoor Design Temperature		
Winter (Dry Bulb F)	Summer (Dry Bulb F)	Summer (Wet Bulb F)
3	91	73

13.2.5.2 Identified Needs and Issues

During the Needs Assessment meetings with GLWA O&M staff, the following HVAC issues were noted:

- PACU-1 requires replacement.

During the discussions with GLWA's HVAC contractor the following historical issues were noted:

- PACU-1 requires frequent maintenance to keep running: GLWA's HVAC contractor noted that PACU-1 at Seven Mile has had issues very similar to unit at Puritan-Fenkell, including damper problems, actuator problems, refrigerant leaks and wiring issues.
- SF-1 and SF-2 motorized dampers are not fully functional.
- SF-2 has audible motor bearing problems.

During site investigations (June 2020), the following observations were noted:

- SF-1 and SF-2 were functional but had damaged duct connections.
- The motorized dampers for SF-1 and SF-2 were seized and not fully open.
- HVU-3 is difficult to access for maintenance.

13.2.5.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

HVAC Improvements (Project SM-HVAC-1). Due to the numerous HVAC-related assets that require replacement and the additional need to provide monitoring for code compliance in the Odor Control Room and Headworks, all of the identified HVAC improvements are proposed to be in one project – HVAC Improvements. As such, there is only one alternative for this project, which includes:

- PACU-1 Replacement
- Improvements to Enhance Safety in Odor Control Area

- Improvements to Enhance Safety in Headworks Area
- HVU-1 and 2 Replacement
- HVU-3 Replacement (with improved access)
- SF-1 and SF-2 Replacement
- Exhaust Fan Replacement
- Removal of Shunt Channel and Effluent Channel HVAC Equipment

Each of the HVAC-related improvements listed above are described further below:

PACU-1 Replacement. Given the age of PACU-1 (24 years) and the lengthy history of various issues, replacement of PACU-1 with a more efficient modern unit and controls is recommended.

Improvements to Enhance Safety in Odor Control Area. The Odor Control area is classified as a Class I, Division 2 space under NFPA 820 if it is not continuously ventilated at a rate of 6 ACH. The space does not meet the 6 ACH ventilation requirement and does not currently have electrical equipment rated for a Class I, Div 2 environment. HVU-1 is designed to provide 10 ACH of ventilation air in cooling mode but was sized to provide only 2 ACH of outside air in heating mode. Additionally, EF-2 is only designed to operate in cooling mode at 10 ACH. NFPA 820 requires both supply and exhaust fans to operate continuously to unclassify odor control areas.

Given the age of HVU-1 and EF-2 and the problems HVU-1 is exhibiting, Jacobs recommends in-kind replacement of both units. HVU-1 and EF-1 could be replaced with two-speed fans or VFDs to provide 6 ACH continuously during ventilation and heating and 10 ACH in cooling mode.

Regardless of whether the space is unclassified by providing 6 ACH of outside air, NFPA 820 requires the installation of combustible gas detection in the Odor Control area with audible and visible alarms at all entrances to the Odor Control area and within the space.

If ventilation is used to unclassify the space as described above, ventilation flow monitoring of both the supply and exhaust fan is required with visible and audible alarms of a low or no flow condition required at entrances and within the space.

Improvements to Enhance Safety in Headworks Area. HVU-2 serves the Headworks Area, which is classified as a Class I, Division 1 space per the design drawings. Given its age and general condition, HVU-2 should be replaced. Because the electrical equipment in the space is rated for a Class I, Division 1 environment continuous ventilation and ventilation flow monitoring are not required. NFPA 820 does, however, require combustible gas detection with visible and audible alarms at the entrances to the Headworks area and inside the space, which the Headworks area currently does not have. Jacobs recommends making this change to comply with NFPA 820.

HVU-3 Replacement (relocated with improved access). HVU-3 is currently mounted high in the Metering Room space making access for maintenance very difficult (Figure 13-2). Placing HVU-3 lower in the space would make access to the magnetic meter and associated piping very difficult. Jacobs recommends replacing HVU-3 with a unit mounted on a concrete pad on the North side of the building when HVU-3 requires replacement. There is an existing opening for the Meter Room supply air duct, which could be utilized by the outdoor unit. This approach would allow ample space for maintenance and would make removal much easier. Currently, HVU-3 will need to be removed in sections when replacement is necessary.

Figure 13-2. HVU-3 Located in Inaccessible Area Difficult to Access Location

SF-1 and SF-2 Replacement. SF-1 and 2 are functional despite having damaged duct connections. These units will require replacement in the near future. The motorized dampers on the units have seized and will need to be removed or replaced. It is worth noting that the design documents for the Puritan-Fenkell facility (which is very similar to Seven Mile Road) indicated the Basin ventilation units had motorized dampers, which were not seen during the site walkthrough and presumably have since been removed. Motorized dampers are not necessary for this application and add a potential failure point as well as increased maintenance and repair costs. The selection of fans with corrosion-resistant construction should negate the need to have motorized dampers.

Exhaust Fan Replacement. There are five relatively small exhaust fans that are original to the facility and should be included in the replacement project.

Removal of Shunt Channel and Effluent Channel HVAC Equipment. The unit heater, supply and exhaust fans in the Shunt Channel and Effluent Channel are not used and are inoperable. These units could be retired. Portable ventilation could be utilized, if necessary, when operators need to enter these areas.

The alternative evaluation is presented in Table 13-10. **The capital cost for Alternative 1, which is the recommended alternative,** is included in Volume 6 – Appendices, Appendix C under this project title.

Table 13-10. Alternative Evaluation for HVAC Improvements (Project SM-HVAC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	HVAC Improvements	Health and Safety	3	3.00	\$ 858,000	\$ -	\$ 858,000	\$ 286,000	Best Value Alternative
	<i>Definition:</i>	Facility-wide HVAC Improvements	Water Quality & Compliance	3						
	<i>Adv.:</i>	Code compliance, less emergency maintenance, improved asset reliability.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

13.2.6 Electrical

13.2.6.1 Description of Existing System

The Seven Mile facility's electrical system consists of one DTE utility feed from a 750 kVA, 480/277 V, 3-Phase outdoor transformer (secondary metering) and one diesel generator feed from a 350 kW, 480/277 V, 3-Phase stationary generator. The feeds are connected to a 1,200 A MDP with electrically operated breakers and automatic source transfer controls for a 1,200 A bus. The MDP has breakers that feed MCCs and distribution panels. The MCCs and distribution panels then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 13-11 provides a summary of the major electrical equipment for this facility.

Table 13-11. Major Electrical Equipment at Seven Mile

Location	Major Electrical Equipment	Description
Electrical Room	Main distribution panel with ATS	1,200 A, 480/277 V, 3-Phase
Courtyard	Generator (Diesel)	350 kW, 480/277 V, 3-Phase
Electrical Room	MCC-1	400 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	400 A, 480/277 V, 3-Phase

13.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for unsafe working conditions. This issue is further described in the section below.

13.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project SM-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure SM-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the basins. Lighting to meet the required foot-candles and codes for the area.
 - Add exterior power receptacles to assist in the maintenance and operations of the facility including additional power receptacles at the facility's outfall.

The alternative evaluation is presented in Table 13-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$39,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 13-12. Alternative Evaluation for Electrical Improvements (Project SM-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 136,000	\$ -	\$ 136,000	\$ 38,857	Not Applicable
	<i>Definition:</i>	Add additional lighting in basins. Provide exterior power receptacles.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.7 I&C

13.2.7.1 Description of Existing System

Control System: The original PLC control system and hardwired backup control system were installed in 1996 under PC-696. The system has the ability to remotely monitor the operations of the facility and the overall area collection system at SCC.

The existing control system consists of Allen Bradley redundant PLC-5 processors with local I/O for monitoring and control of the facility processes. The system has hardwired backup capabilities to control the facility on an overall control system failure. The PLC's control system network communicates via an Ethernet network to the facility's control system and operator workstation. The workstation currently uses the Rockwell RSView software package that provides the existing operator workstation the additional software applications to provide historical data storage and retrieval, reporting, as well as other functions to monitor and control the system. The local hardwired backup control panel is obsolete and with new redundant control systems, this type of backup hardwired control panel is no longer used. The current system is equipped with a backup radio system to communicate critical monitoring points back to SCC on wide area network failure.

Flow and Level Sensors: Table 13-13 summarizes the level sensors and flow meters at the Seven Mile CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 13-13. Summary of Flow Meters and Level Sensors at Seven Mile CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Shunt Channel	1	Transit-Time (AccuSonic)
Effluent Weir	2	Ultrasonic
Dewatering	1	Magnetic
CSO Level Sensors		
Influent	1	Ultrasonic
Screening Area (Downstream of bar racks)	1	Ultrasonic
Basin	2	Ultrasonic
Effluent Channel	1	Ultrasonic
Dewatering Well	1	Ultrasonic
NWI	1	Ultrasonic
River	1	Ultrasonic
Chemical System Flow Meters		
Secondary Water	1	Magnetic
Chemical Feed	1	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic

13.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- Replacement options for valve control network for the chemical feed system is discussed in detail in Section 5.4.6. The cost/benefit of the hardwired control was not favorable and therefore was not considered further.
- Update control system. GLWA is currently developing a RFPs for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under "Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities." The project will replace the existing PLC-5 control system and backup local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an ongoing project that has already been included in the CIP.

13.2.7.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no I&C related issues that that would be classified as capital improvement "needs."

13.2.8 Site

13.2.8.1 Description of Existing Site

The Seven Mile CSO Facility was constructed in 1994. Access to the site is off of Shiawassee St. through a 25-ft wide sliding gate. Site security is provided by perimeter fencing comprised of a 6-ft high chain-link fence along the west side of the CSO building along Shiawassee St. The parking lot consists of 4-in. thick asphalt pavement with 8-in. gravel base. Concrete sidewalks are 5 ft wide and 4 in. thick with 4-in. sand base. The top of most of the basin roof area is used as a parking lot by the nearby church.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

13.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the section below.

- There is no security fencing around the north, south and east sides of the Seven Mile CSO Control/Headworks Building.
- The Courtyard floor does not provide adequate slope for the rain/snow runoff to flow to the scuppers and consequently ponds on the floor surface.
- The existing hatch cover plates are heavy and difficult to remove.

13.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section, by potential project, along with the recommended alternative.

Security Fencing (Project SM-Site-1). There is currently no security fencing around the north, south and east sides of the Seven Mile CSO Control/Headworks Building. Painted chain-link fencing exists on the west side of the CSO building along Shiawassee St. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Extend Security Fencing Around Entire Building.** It is recommended that security fencing be installed along the remainder of the building site to secure building operations.

The alternative evaluation is presented in Table 13-14. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 0.9 higher than the Do Nothing Alternative (Alternative 1) based on the improved safety. Because of the importance of this issue related to safety, **Alternative 2 – Extend Security Fencing Around Entire Building is the recommended alternative.**

Table 13-14. Alternative Evaluation for Security Fencing (Project SM-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Security issue.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Extend Security Fencing Around Entire Building	Health and Safety	5	3.57	\$ 347,000	\$ -	\$ 347,000	\$ 97,290	Not Applicable
	<i>Definition:</i>	Security fencing to be installed along the remainder of the building site.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Secure building operations	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

Site Improvements (Project SM-SITE-2). Due to the relatively small nature of some of the site related projects identified as improvements, all of the identified site improvements are proposed to be in one project – Site Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Site Improvements** including,
 - Improve Drainage in the Courtyard
 - Replace Existing Effluent Gate and Shunt Channel Hatches

Each of the site related improvements listed above is described further below:

Improve Drainage in the Courtyard. The Courtyard at the Headworks of the Seven Mile CSO Basin has an open roof and is exposed to rain and snow falling on the floor surface. There are scuppers in the base of the east wall of the Courtyard to allow runoff to drain through the Courtyard wall onto the basin roof surface outside the wall. The Courtyard floor, however, does not provide adequate slope for the runoff to flow to the scuppers and consequently ponds on the floor surface. To alleviate the water ponding, it is recommended that holes be cored through the courtyard floor to the basin below. Recessed area drains can be installed in the cored holes to funnel floor drainage to the basin.

Replace Existing Effluent Gate and Shunt Channel Hatches. There are three hatch openings over the three existing effluent butterfly gates and their corresponding stop log guides. The hatch openings at the effluent gates have dimensions of 8 ft by 3 ft. The existing hatch cover plates are heavy and difficult to remove. GLWA would like to replace cover plates with an alternative plate design that improves accessibility to the gates and stop log guides below.

There are also two hatch openings over the two shunt channel butterfly gates and their corresponding stop log guides. These hatch openings also have dimensions of 8 ft by 3 ft. These hatch covers have been recently replaced and are not included in the cost estimate.

The improvements at these locations should be coordinated with the potential modification of this basin to a complete capture facility, described in Section 13.1.2.

The alternative evaluation is presented in Table 13-15. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$35,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Site Improvements is the recommended alternative.**

Table 13-15. Alternative Evaluation for Site Improvement (Project SM-SITE-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Safety issues.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Site Improvements	Health and Safety	4	3.50	\$ 122,000	\$ -	\$ 122,000	\$ 34,857	Not Applicable
	<i>Definition:</i>	Improve drainage in the Courtyard and replace existing effluent gate and shunt channel hatches.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved drainage and ease of O&M.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.9 Architectural

13.2.9.1 Description of Existing Facilities

The Seven Mile Road CSO facility consists of chemical room, utility support (electrical), control room, work room, odor control room, screen room, miscellaneous other rooms and a courtyard.

13.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a roof replacement evaluation and a detailed assessment of architectural issues, as described in the following paragraphs.

Evaluation of Type of Future Roof Replacement. Jacobs reviewed the results of a roof assessment and prepared a 60-year life-cycle cost analysis between shingled roof and metal roof. Based on the results of this evaluation, which shows lower life cycle cost for shingled roof, Jacobs recommends replacement of the shingled roof with shingles when the roof is ready for replacement. The analysis is presented in Table 13-16. As such, the roof should be replaced in-kind and the costs and schedule for the roof replacement will come from the SRP.

Table 13-16. 60-Year Life-Cycle Cost Evaluation of Shingled vs. Metal Roof for Seven Mile Facility

	Shingle Roof	Metal Roof
Replacement Cost ^a	\$93,000	\$311,000
Replacement Interval	20 years	60 years
Number of Roof Replacements During 60 Years	3	1
Total Life-Cycle Cost (NPV) Discounted at 2.4%	\$252,000	\$311,000

^a Based on 6,225 ft² roof area; \$15 ft² for shingle roof and \$50/ ft² for metal roof.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering systems
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that that there is no access to the Headworks area and the Courtyard during a power outage.

13.2.9.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (SM-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Architectural Rehabilitation.** Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation includes the following:
 - Remove and replace sealant around doors, windows and other wall penetrations
 - Remove and replace sealant at all control/ expansion wall joints
 - Remove corrosion at bottom of man door and coat steel framing
 - Remove paint debonding from wall, clean and coat
 - Address door hardware issues
 - Remove painted debonding from roof framing, clean and coat

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure SM-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 13-17. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, Alternative 2 is the recommended alternative.

Table 13-17. Alternative Evaluation for Architectural Rehabilitation (Project SM-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 156,000	\$ -	\$ 156,000	\$ 50,323	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

Access to Courtyard and Headworks (Project SM-ARCH-2). If there is a power outage and the generator does not kick on, there would be no access to the Headworks area and the Courtyard. There are two alternatives to address this issue:

- 1) **Alternative 1: Do Nothing.**
- 2) **Alternative 2: Additional Access to Courtyard and Headworks.** GLWA requested access doors be provided from the Courtyard to the outside. Two 3-ft by 7-ft heavy-duty hollow metal double doors and frame with commercial grade stainless steel hardware is recommended to provide emergency access.

The alternative evaluation is presented in Table 13-18. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. The NPV/Benefit cost for Alternative 2 is \$10,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved safety with this alternative, Alternative 2 – Additional Access to Courtyard and Headworks is the recommended alternative.**

Table 13-18. Alternative Evaluation for Access to Courtyard and Headworks (Project SM-ARCH-2)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None.	Capacity Enhancement	3						
	<i>Disadv.:</i>	No access to the Headworks and Courtyard, during a power outage.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Additional Access to Courtyard and Headworks	Health and Safety	4	3.50	\$ 34,000	\$ -	\$ 34,000	\$ 9,714	Not Applicable
	<i>Definition:</i>	Install door into Courtyard.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Provides emergency access to the Headworks and Courtyard during a power outage.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

13.2.10 Safety

13.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

13.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 13-19. The capital improvement project to address these issues is included in the table.

Table 13-19. Identification of Capital Improvements for Safety Issues

Location	Description	Corrective Action from Safety Inspection Report	Capital Improvement Project
Chemical Room	Emergency eyewash/shower 0943390 outside containment	Add eyewash/shower inside tank containment	Safety Improvements (Project SM-SAFE-1)
Utility Tunnel	Ladder at end of tunnel has an exit sign but hatch is locked.	Add placard to fixed ladder "Not An Exit." Replace existing exit sign with directional exit sign away from ladder access.	Exit Sign Improvements ^a

^a This task is being addressed in a separate project under TOES. As such, capital costs are not included.

13.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project SM-SAFE-1). This project should address the safety issues identified above. These issues include:

- Add eyewash/shower outside containment in the Chemical Room
- Address fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency, the Table 13-20 showing the one alternative is presented below.

Table 13-20. Alternative Evaluation for Safety Improvements (Project SM-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	3	3.00	\$ 92,000	\$ -	\$ 92,000	\$ 30,667	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection, and eye wash.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						

13.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at Seven Mile CSO Facility.

13.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the Seven Mile CSO facility, Table 13-21 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 13-21, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 13-21. Listing of Asset Condition Assessments for Seven Mile Facility

Asset Type	Total No. of Assets in Asset Type	No. of Visual Condition Assessments	No. of Detailed Condition Assessments	% of Assets with Condition Assessment

WATERHTR	0	0	0	N/A

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The one gas detector is a portable unit and was not assessed.

^c Three inactive pumps are listed in WAM - Basin 1 Sample Pump, Basin 2 Sample Pump, and Shunt Channel Sample Pump. These pumps are being considered for removal from WAM.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the Seven Mile Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

13.3 Capital Planning for Seven Mile CSO Facility

13.3.1 Summary of Capital Improvement Plan Projects

Table 13-22 provides a summary of the recommended CIP projects and associated capital costs for the Seven Mile CSO facility based on the alternative evaluations conducted for this facility.

Table 13-22. Summary of Recommended Projects at Seven Mile CSO Facility

Project No.	Alternative	Description	Total Project Cost
SM-WWMP-1	2	Convert to Complete Capture Basin	\$ 2,500,000
SM-FD-1	2	Provide Access to Tipping Buckets for Maintenance	\$ 125,000
SM-FD-2	2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
SM-HVAC-1	1	HVAC Improvements	\$ 858,000
SM-ELEC-1	2	Electrical Improvements	\$ 136,000
SM-I&C-1	1	Control System Upgrade	Ongoing Project
SM-SITE-1	2	Extend Security Fencing Around Entire Building	\$ 347,000
SM-SITE-2	2	Site Improvements	\$ 122,000
SM-ARCH-1	2	Architectural Rehabilitation	\$ 156,000
SM-ARCH-2	2	Additional Access to Courtyard and Headworks	\$ 34,000
SM-SAFE-1	1	Safety Improvements	\$ 92,000

13.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 13-23. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 13-23. Capital Improvement Plan Projects for Seven Mile CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
SM-1 Flushing Improvements	\$ 337,000	2032 <i>Timing based on Best judgement</i>	SM-FD-1	Provide Access to Tipping Buckets for Maintenance	\$ 125,000
			SM-FD-2	Access to Dewatering Force Main for Inspection and Cleaning	\$ 90,000
			SM-SITE-2	Site Improvements	\$ 122,000
SM-2 HVAC Improvements	\$ 858,000	2027 <i>Timing based on asset condition</i>	SM-HVAC-1	HVAC Improvements	\$ 858,000
SM-3 Electrical Improvements	\$ 136,000	2032 <i>Timing based on best judgement</i>	SM-ELEC-1	Electrical Improvements	\$ 136,000
SM-4 Facility-Wide Safety and Architectural Improvements	\$ 629,000	2023 <i>Project should be initiated as soon as possible</i>	SM-SITE-1	Extend Security Fencing Around Entire Building	\$ 347,000
			SM-ARCH-1	Architectural Rehabilitation	\$ 156,000
			SM-ARCH-2	Additional Access to Courtyard and Headworks	\$ 34,000
			SM-SAFE-1	Safety Improvements	\$ 92,000
SM-5 Convert to Complete Capture Basin	\$ 2,500,000	2030 <i>Timing based on general CSO project priorities</i>	SM-WWMP-1	Convert to Complete Capture Basin	\$ 2,500,000

The scheduling of projects that are replacing existing assets is influenced by the condition and remaining life of the existing assets. Table 13-24 and Table 13-25 provide information related to the assets in these projects to aid in the scheduling of these projects. For example, Table 13-24 indicates that SM-HVAC-1 project has 12 assets that has an average condition score of 1.61 and an average replacement date of 2034. Although the average replacement date suggests 2034, the SM-HVAC-1 project was moved up to 2027 due to equipment age and performance.

Table 13-24. Information for Assets with Condition 1-4 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 1-4)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
SM-HVAC-1	12	1.19	1.61	2.15	20	2034	\$ 224,880

Table 13-25. Information for Assets with Condition 5 in Capital Improvement Projects

NA PROJECT NUMBER	TOTAL NO. OF ASSETS (Condition 5)	AVG CoF SCORE	AVG CONDITION SCORE	AVG RISK SCORE	AVG LIFE EXPECTANCY	AVG REPLACEMENT DATE	TOTAL REPLACEMENT COST
SM-HVAC-1	0	0.00	0.00	0.00	N/A	N/A	\$ -

13.3.3 20-Year Capital Outlay Plan

Table 13-26 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

Table 13-26. 20-Year Capital Outlay Plan for Seven Mile CSO Facility

CSO Facility and SRP Year	Annual Total	Common Support Systems	Screening Systems	Retention System	Disinfection System	Pumping System	Odor Control System	HVAC System	Electrical Distribution System	SCADA System	Safety and Security System	Road and Grounds System	Infrastructure System
2021	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -
2022	\$ 335,368	\$ -	\$ -	\$ 322,802	\$ -	\$ -	\$ -	\$ -	\$ 12,566	\$ -	\$ -	\$ -	\$ -
2023	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -	\$ -

Notes:

Explanation of large capital outlays in first two years:

- Retention System: Two influent slide gate (SG-1 and SG-5; \$157,000 each) received a score of 5 because the gates were locked out at the time of the Condition Assessment. Two flushing water ball valve (FW-1 and FW-8; \$4,000 each) received a score of 5 because the actuator for the valve was not functional or had been removed.

14. St. Aubin CSO Control Facility

14.1 General Facility Description and Future Capacity Considerations

14.1.1 General Facility Description

The St. Aubin CSO Facility is an SDF with 2.4 MG of storage, and a treatment capacity of 250 cfs. It was constructed in 2002. The facility has a nearly 1/3-mile long effluent conduit used for disinfection contact time before discharge into the Detroit River. The facility consists of an underground headworks, chemical room, odor control area, supply fan room, control room, and utility support (electrical, emergency generator, and mechanical rooms) and a restroom. The facility has an offsite sample building at the end of the outfall.

Schematics of the facility, including a process flow diagram, are included in Volume 6 – Appendices, Appendix G.

14.1.2 Future Capacity Considerations

Based on a review of the WWMP, there were no future increased capacity considerations identified at this facility.

14.2 Facility Assessment

14.2.1 Screening

14.2.1.1 Description of Existing System

The St. Aubin CSO Facility has two vertical ROMAG screens that were installed in 2002. Screenings are retained in the influent chamber during the storm. After the storm event, the screenings are pumped to the Detroit River Interceptor for eventual removal at the WRRF.

Table 14-1 provides an overview of the existing screening system at St. Aubin CSO facility.

Table 14-1. Overview of Existing Screening System at St. Aubin CSO Facility

Parameter	Value
Treatment Capacity (cfs)	250
No. of Screens	2
Manufacturer	Westech ROMAG
Screen Type	Raked Vertical Bar Screens
Opening Size	4-mm spacing
Depth or Length / Width	3 ft 7 in. /22 ft 0 in.
Screen Cleaning	Mechanical Comb
Screening Removal	Pumped to Toward Treatment Sewer and to WRRF

14.2.1.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issue was identified related to the screens:

- Evaluate potential improvements to existing screening system to remove screenings during wet weather.

14.2.1.3 Description and Evaluation of Alternatives

The evaluation of the need identified above is presented in this section.

Replace Screens with Improved Screens. Due to the configuration of the St. Aubin CSO Facility, the screenings accumulate during a wet weather event in the influent chamber in front of the screens. Although each screen has a mechanically operated comb that cleans the screens during a wet weather event, the screenings continue to accumulate in front of the screens. Some provisions were made in the original system to direct the screens to the dewatering well; however, these were found to be ineffective.

Jacobs investigated a new type of screen by Enviro-Care (SAVI Overflow Spillway – Model VSE-700/6) that could transport the screenings away from the influent chamber and convey them using an integral screw conveyor to the dewatering chamber (see Figure 14-1). The manufacturer developed a layout within the existing facility that would allow the screenings to discharge near the dewatering chamber. A short connection would be required to connect the discharge end to the facility's Dewatering Chamber.

Figure 14-1. Enviro-Care SAVI Overflow Spillway Screen

There are a number of concerns with the Enviro-Care screen and the retrofit of this screen into the St. Aubin facility:

- The proposed screen, within the given facility layout, only has a capacity of 217 cfs, which is less than the facility capacity of 250 cfs.
- The proposed screen has 8-mm openings. The other GLWA SDF with perforated openings (Baby Creek) has perforations of 6-mm. The Enviro-Care screen is available in 6-mm; however, the capacity of a screen with 6-mm perforations would be further reduced. Although the perforation size could potentially be negotiated with Michigan EGLE, there is a risk that EGLE would require 6-mm perforations.

Given the fact that the screen does not meet facility's design capacity of 250 cfs, it is not recommended for further consideration.

14.2.2 Disinfection

14.2.2.1 Description of Existing System

The sodium hypochlorite disinfection system consists of two FRP tanks, two low-rate diaphragm pumps, three high-rate diaphragm pumps, two rapid mix zones, and seven induction mixers. There are two ROMAG screens discharging into a screened effluent channel. From there screened effluent flows to two disinfectant rapid mix zones. There are three induction mixers per disinfectant rapid mix zone consisting of one pair of mixers upstream and one mixer downstream of a concrete baffle wall that directs all flow down and past the mixers. There is also one induction mixer in the influent channel upstream of screening referred to as prechlorination and the influent channel mixer. The discharges of Low-rate Pump 1 and High-rate Pump 2 combine and serve disinfectant rapid Mix Zone 1. The discharges of Low-rate Pump 3 and High-rate Pump 4 combine and serve disinfectant rapid Mix Zone 2. Sodium Hypochlorite Pump 5 serves the prechlorination mixer or as a backup to either rapid mix zone. Flow is metered from each pump and then flow is split in a manifold to the three induction mixers in each disinfectant rapid mix zone. The manifold includes a solenoid valve, manual valve, and a sight flow indicator to each induction mixer. Flow splitting between induction mixers is primarily dependent on equal back pressure valve settings to the induction mixers. Some valves are inaccessible due to their height on the wall.

Table 14-2 provides an overview of the existing disinfection system at St. Aubin CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G.

Table 14-2. Overview of Existing Disinfection System at St. Aubin CSO Facility

Parameter	Value
Treatment Capacity (cfs)	250
Design Feed Strength (% hypochlorite)	10
Max. Dosage at Design Flow (mg/L Cl ₂)	38
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	5,200
Type	FRP
Pumps	
Number	5 Total; 2 low-rate, 5 high-rate
Capacity (gpm)	Low-rate: 7.6, High-rate: 22.8
Type	Hydraulic diaphragm
Mixers	
Number / Type	7 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC7.5FX / 7.5 hp / Water Champ

14.2.2.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations.

This facility, however, will be treated differently in this project because Hazen performed a Sodium Hypochlorite Storage and Feed System Assessment, dated October 15, 2019, for disinfection system improvements and AECOM is developing scope for an upcoming design project for facility improvements, including chemical feed pumps, relocation of pump control panels, mixer modifications, and building storage improvements.

Sodium Hypochlorite Feed and Storage System Improvements (Project STA-DIS-1). The recommendations from the Hazen report, although not identical, are similar to the chemical feed system improvements recommended in CS-299. Chemical feed pumps as peristaltic (hose) pumps or mag drive centrifugal pumps were recommended for further consideration during detailed design. It is recommended that the firm selected for detailed design consider the improvements from this CS-299 Facilities Assessment evaluation of the disinfection systems to best standardize this system with the other future systems. Other disinfection-related improvements were recommended as part of this project, including operation in automatic mode and provisions to flush the feed system piping.

14.2.2.3 Description and Evaluation of Alternatives

Because this is an upcoming project (CIP 260617), an alternative evaluation was not conducted, and capital costs are not included in this report.

14.2.3 Odor Control

14.2.3.1 Description of Existing System

The St. Aubin odor control system consists of a Calgon Carbon PHOENIX automatic regeneration system, which utilizes radial flow canisters filled with Centaur HP carbon. Several years ago, Calgon Carbon sold its odor control equipment division to Continental Carbon along with the Centaur HP carbon. The unit consists of 30 canisters and an odor control fan, which delivers air through the carbon filters or directly to the exhaust stack. Air is pulled from the screening and disinfection chambers by the odor control fan and is uniformly distributed through the carbon canisters, bringing the air in direct contact with the carbon. The regeneration process consists of programmed filling of a single compartment of canisters with water, letting the water sit for a period of time, and then draining and drying the carbon.

The system was installed in 2002. The carbon has not been replaced since installation. Overall, the system is in good condition. The odor control system does not have an air permit.

Per GLWA, no odor complaints have been received for at least the past three years.

14.2.3.2 Identified Needs and Issues

The identified needs for the St. Aubin CSO facility are included in the following sections. The following issue was identified:

- Evaluate improvements to enhance safety around odor control system inside building, if needed.

Improvements to Enhance Safety Around Odor Control System. Hazen prepared a preliminary design report for the St. Aubin CSO Facility entitled *Sodium Hypochlorite Storage and Feed System Assessment*, dated October 15, 2019. In this report, they investigated the facility's current compliance with NFPA 820. Based on this evaluation, the following deficiencies were noted:

- Air flow monitoring
- Horns and strobes
- Backup power supply for horns/strobes and flow monitoring.

The Hazen report recommends that these items be included in the upcoming facility improvement project. This issue is being addressed in an upcoming project (CIP 260617).

The recommendations related to the odor control system below are based on the Jacobs team evaluation of the existing system.

Future Carbon Replacement Considerations. Centaur HP carbon contains a catalyst that oxidizes H_2S and converts it to sulfuric acid. As a result, the carbon can be restored for H_2S uptake by water washing. As discussed for the Baby Creek CSO Facility in Section 6.2.3.2, the Centaur HP carbon loses capacity over time. One typically determines the need for carbon regeneration by measuring the H_2S concentration in the discharged air. When H_2S is still detected in the discharged air after a regeneration cycle, the carbon is spent and should be replaced. Centaur HP replacement is about every two years under typical municipal wastewater applications. GLWA CSO facilities are not typical applications as the odor control systems are operated infrequently and are likely under low loads from H_2S and odorous compounds meaning the carbon will last a lot longer. According to O&M staff, the St. Aubin system is regenerated every two months based on the recommended PM in the manufacturer's O&M manual. The system may not need to be regenerated that frequently given the light load. The existing practice of carbon regeneration every two months may continue, but carbon capacity may decrease with each washing due to compounds in the regeneration water that adsorb to the carbon and that less than 100 percent of the sulfuric acid generated during the adsorption process is removed. Laboratory analysis of the carbon for H_2S capacity is likely the best way to determine the remaining carbon life for the St. Aubin system. Sampling the discharged air for H_2S breakthrough likely will not be an effective indicator due to the likely low H_2S load.

Although the current carbon capacity may be significantly less than the original capacity, the lack of any odor complaints from the community suggests that any odors being discharged are either not noticeable, not objectionable or are masked by other odor sources in the area. It is recommended that GLWA sample the influent and discharge of the odor control system during at least two storm events in the summer months (i.e., the period with the highest odor potential) to better understand the magnitude of odors generated from the CSO facility.

If the influent H_2S levels are low, replacement of the carbon would not be needed. Further testing could then be performed to determine if the carbon could be removed and not replaced. A non-detectable concentration of H_2S in the influent air means the system can likely operate without carbon. The following bullets provides considerations for the carbon replacement.

- The existing Centaur HP carbon in the PHOENIX system has an H_2S capacity of 0.09 g H_2S /cubic centimeter of carbon (15 percent by weight). The cost for replacement of the carbon is about \$20,400 (30 canisters at \$680/canister). The cost includes a new canister, sealing and loading the canister with Centaur HP carbon, and delivery.
- ECS manufactures a direct equivalent to Centaur HP carbon at a lower cost. ECS reuses the existing canisters. The cost for ECS's water regenerable catalytic carbon is about \$12,750 (30 canisters at \$425/canister). The cost includes shipping the full canisters to ECS, disposal of the spent carbon, cleaning the canisters, charging the canisters with ECS water regenerable catalytic carbon, and delivery.

As noted above, an evaluation of influent and discharge H_2S concentrations is recommended prior to carbon replacement. When it is time to replace the Centaur HP carbon, GLWA should evaluate replacing it with either Centaur HP or ECS water regenerable catalytic carbon.

14.2.3.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no odor control-related issues that that would be classified as capital improvement "needs".

14.2.4 Flushing and Dewatering

14.2.4.1 Description of Existing System

Dewatering System: The Headworks (screening and disinfection) area and the effluent conduits are dewatered after a storm event using three dewatering pumps located in the Headworks Dewatering Well.

The dewatering of the effluent conduit also relies on two submersible dewatering pumps located at the end of the effluent conduit. These pumps convey any water remaining at the end of the effluent conduit (after the Headworks Dewatering Pumps have removed as much of the water as possible) back to the Headworks Dewatering Well.

Flushing System: The original facility did not include a flushing system for the effluent conduits. Around 2010, a flushing system for the final one-third of the effluent conduits was installed. This system consists of two 100 gpm flushing pumps located at the outfall, just downstream of the backwater gates. These pumps use Detroit River water to pump to two locations in the effluent conduit with spray nozzles.

A manually operated, gravity flushing system consisting of a pipe with nozzles is provided for the area upstream of screens. This system uses water captured in the disinfection chambers as flushing water. The area upstream of the screens is dewatered first, while water remains in the mixing chambers. The head pressure from the water in the mixing chambers provides the pressure in the flushing pipe to provide a sufficient flush of the floor area.

Table 14-3 provides an overview of the existing flushing and dewatering system at St. Aubin CSO facility.

Table 14-3. Overview of Existing Flushing and Dewatering System at St. Aubin CSO Facility

Parameter	Value
Headworks Dewatering and Flushing System	- Headworks (screening and disinfection) area is dewatered using three 1,100 gpm dewatering pumps located in the Headworks Dewatering Well. - Manually operated flushing system consisting of a pipe with nozzles for area upstream of screens.
Effluent Conduit Dimensions	10 ft. × 10 ft.
Effluent Conduit Dewatering and Flushing System	- Effluent conduit is dewatered using three 1,100 gpm dewatering pumps located Headworks Dewatering Well. - There are two 200 gpm submersible dewatering pumps located at the end of the effluent conduit, which pump back to the Headworks Dewatering Well. - There are two 100 gpm flushing pumps that provide water to a spray flushing system for the second half of the effluent conduit.

14.2.4.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The following issues were identified related to the flushing and dewatering system:

- Settled solids buildup in the 10-ft by 10-ft effluent conduit for this facility. A flushing system was installed since the facility was constructed; however, this system has not proved effective at removing the solids buildup.
- Provide flushing system in mixing chambers to flush accumulated solids from the floor.

14.2.4.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

New Effluent Conduit Flushing System (Project STA-FD-1). There are two alternatives for addressing the solids buildup in the effluent conduits and the chemical mixer chambers. These alternatives include:

- 1) **Alternative 1: Do Nothing/ Contractor Cleanout**
- 2) **Alternative 2: New Effluent Conduit Flushing System.** This alternative includes mounting a 6-in. HDPE flushing header along both sides of the effluent conduit approximately 2 ft above adjacent lower concrete surface. See Volume 6 – Appendices, Appendix B, for Figure STA-FD-1-ALT-2 showing conceptual layouts. HDPE pipe is recommended for this application due to its corrosion resistance and its flexibility that imparts resistance to damage from impacts by heavy debris suspended in wet weather flows. The flushing header should be specified with an adequate wall thickness to allow for directionally drilled holes (up to 0.75-in.-diameter) that create a water jet aimed in a specific direction. The proposed hole spacing along the header will be approximately 18 to 24 in. A cursory analysis based on channel dimensions, slopes and anticipated grit sizes indicates that a minimum total flow rate of 3,500 gpm is required to adequately resuspend sediment from the floor of the square conduit and maintain adequate volume and velocity to carry the sediment to the terminus ends.

A small valve is also recommended at the terminus end of each spray header with a rising stem and automated actuator mounted outside of the chamber. At the start of the cleaning cycle, these valves will automatically open for several minutes, allowing the potable water to flush any materials that have entered the header through openings out the open end. These terminus valves would close, and the header would pressurize and start spraying.

Two new flushing pumps (approx. 5,200 gpm, 100 ft total dynamic head) will be installed at the end of the conduit and the existing flushing pumps removed. The pump size has been selected to provide a 1.5 safety factor on flushing anticipated grit volumes and particle sizes. The existing flushing system will also be removed. The new flushing pumps will be manifolded with a control valve to allow flushing of one-half of the conduit at a time. The existing flushing pump electrical system is assumed to have adequate load capacity for the new pumps; however, an allowance is included for rewiring and new conduits in the cost estimate. An allowance is also included for SCADA and PLC/human-machine interface programming.

Existing dewatering pumps may be overwhelmed by the large flushing flows generated by continuous post-event cleaning. The costs for this improvement include replacing the existing 100 gpm and 200 gpm dewatering pumps with larger pumps (1,000 gpm) and allowances for replacing some of the exposed discharge piping and valves. To avoid replacing the dewatering pumps, the flushing system could be operated in 15-minute intervals with adequate time between to drain the flushing water and sediment. Preliminary analysis indicates a total of 2 hours of flushing per pump unit should be considered as a starting point for operations. GLWA staff may increase or decrease the number of intervals over time as the effectiveness of the cleaning system is observed. The final designer should evaluate and refine the flushing volumes and generated header nozzle velocities using a sediment fate/transport model, CFD or lab scale model. Grit characterization is strongly recommended for proper sizing.

The likely flow management scenario assumed for construction will be to isolate the facility structurally or using existing controls. Seasonal restrictions are also assumed such that much of the work will take place in the dry season to minimize inundation risk during construction.

GLWA O&M staff also requested that a dedicated flushing system be provided for the two chemical mixing channels to flush accumulated solids from the floor after a storm event. A new flushing system

pipled from the existing NPW line in the “basin” area, extending down to the mixing chamber floors and drilled holes through HDPE pipe is recommended to address this issue. Figures (Figure STA-FD-1-ALT-2) that show the conceptual layout of this improvement are included in Volume 6 – Appendices, Appendix B.

The alternative evaluation for these alternatives is presented in Table 14-4. The sources of costs used in this evaluation are listed below:

- Contractor cleanout of this area is estimated to be \$400,000 every 5 years, based on costs at other screening and disinfection facilities. This O&M cost is annualized to \$80,000.
- The capital cost for the flushing system (Alternative 2) is included in Volume 6 – Appendices, Appendix C under this project title. It should be noted that the capital cost includes an allowance of \$90,000 for cleaning the influent channel prior to installing the flushing system. The \$140,000 equates to about \$400,000 after contingencies, and standard markups for design, construction assistance and contractor overhead and profit have been applied.
- The O&M costs for the current and proposed flushing system (Alternatives 1 and 2) are based on using Detroit River water, so there is no cost for water usage.
- Alternative 2 will provide the benefit of improved effluent water quality and hydraulic capacity because the conduit will be cleaned after every event. This will prevent the scouring of built up solids accumulation and will maintain hydraulic capacity of the effluent conduits.

This evaluation shows that Alternative 2 has the lowest NPV/Benefit cost and is the Best Value Alternative. Because of the improved health and safety, effluent water quality and hydraulic capacity, **Alternative 2 – New Effluent Conduit Flushing System is the recommended alternative.**

Table 14-4. Alternative Evaluation for New Effluent Conduit Flushing System (STA-FD-1)

Alt.	Description			Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing/ Contractor Clean-out	Health and Safety		2	2.10	\$ -	\$ 80,000	\$1,687,171	\$ 803,415	
	<i>Definition:</i>	Allow solids to build up and have a Contractor clean out the conduit, as needed	Water Quality & Compliance		2						
	<i>Adv.:</i>	No system to maintain	Capacity Enhancement		2						
	<i>Disadv.:</i>	Significant build-ups can impact facility hydraulic capacity. Cleaning effluent area is a high-risk activity, which requires significant GLWA coordination. Solids build-up may scour out of basin and negatively affect effluent water quality.	Component Performance		3						
	<i>Comments:</i>	None	O&M Ease		2						
2	<i>Alt. Name:</i>	New Effluent Conduit Flushing System	Health and Safety		5	4.18	\$ 2,472,000	\$ -	\$2,472,000	\$ 590,916	Best Value Alternative
	<i>Definition:</i>	Provide flushing system in effluent conduit using river water and provide a flushing system in the chemical mixing area.	Water Quality & Compliance		4						
	<i>Adv.:</i>	Minimizes solids from being scoured from floor and affecting effluent water quality. No confined space entry to clean conduit.	Capacity Enhancement		4						
	<i>Disadv.:</i>	Increased maintenance of equipment.	Component Performance		3						
	<i>Comments:</i>	None	O&M Ease		4						

14.2.5 HVAC

14.2.5.1 Description of Existing System

The St. Aubin CSO facility consists of an underground headworks, chemical room, odor control area, supply fan room, control room, and utility support (electrical, emergency generator, and mechanical rooms) and a restroom. The facility has an offsite sample building. Table 14-5 provides a summary of the major equipment for the facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, and emergency shower/eye wash. Emergency shower/eye washes are addressed, if safety issues were discovered, in Section 14.2.10.

Table 14-5. Major HVAC Equipment at St. Aubin CSO Facility

Location	Unit No.	Description	Capacity (Per Unit)
Headworks	SF-1	Supply Fan (Basin)	9,555 CFM
Chemical Room	HV-1	Heating Ventilating Unit (Mech Rm)	2,710 CFM
	EF-2	Exhaust Fan	3,010 CFM
Electrical Room	HV-2	Heating Ventilating Unit (Mech Rm)	4,665 CFM
	EF-3	Exhaust Fan (Odor Control Rm)	3,720 CFM

Table 14-6 provides a summary of the basis of design performance criteria for HVAC systems at St. Aubin and Table 14-7 provides the outdoor Basis of Design conditions.

Table 14-6. St. Aubin Original Indoor Basis of Design Performance Criteria Summary

Location	Area Electrical Classification	Basis of Design		
		Indoor Design Temperature		Ventilation Design Criteria
		Winter (F)	Summer (F)	
Headworks	Class I, Div 1, Group D	N/A	N/A	12 ACH (Occupied)
Mechanical Spaces	Unclassified	60	96	Heat Relief
Office, Sampling Room, and Toilet Room	Unclassified	70	78 F Dry Bulb, 50% Relative Humidity	15 cfm per occupant
Odor Control Room	Unclassified for areas greater than 3 ft from odor control vessel. Class I, Div 2, Group D for areas closer than 3 ft.	60	96	6 ACH

3	91	73

report, they investigated the facility's current compliance with NFPA 820. Based on this evaluation, the following ventilation related deficiencies were noted:

- Air flow monitoring
- Horns and strobes
- Backup power supply for horns/strobes and flow monitoring

The Hazen report recommended these items should be included in the upcoming facility improvement project. Jacobs agrees with the proposed recommendations and would add that in addition to the Hazen recommendations, combustible gas detection and alarm of gas in excess of 10 percent of the lower explosion limit is also required by NFPA 820 in the Odor Control Area. These recommendation are being addressed in an upcoming project (CIP 260617).

14.2.5.3 Description and Evaluation of Alternatives

Based on discussion in the previous section, there were no HVAC-related issues that that would be classified as capital improvement “needs”.

14.2.6 Electrical

14.2.6.1 Description of Existing System

The St. Aubin electrical system consists of one DTE utility feed from a 480 V, 3-Phase outdoor transformer (secondary metering) and one generator feed from a 175 kW, 480 V, 3-Phase stationary diesel generator. The utility feed is connected to a 600 A motor control center (MCC-B) with a 200 A sub-feed connection to a 225A ATS. The ATS then feeds a distribution panel with one 200 A breaker and one 150 A breaker, which feeds two MCCs (MCC-A and MCC-C, respectively). The MCCs feed the various pumps, valves, motors, transformers, panels, etc. at the facility. Table 14-8 provides a summary of the major electrical equipment for this facility.

Table 14-8. Major Electrical Equipment at St. Aubin

Location	Major Electrical Equipment	Description
Generator Room	Generator (Diesel)	175 kW, 480/277 V, 3-Phase
Electrical Room	MCC-A	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-B	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-C	600 A, 480/277 V, 3-Phase

14.2.6.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. The lighting is poor or non-existent in some locations, making for less safe working conditions. These lighting needs are in addition to the recent LED lighting project. This issue is further described in the next section.

14.2.6.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Electrical Improvements (Project STA-ELEC-1). The lighting is poor or non-existent in some locations, making for less safe conditions. There are two alternatives to address the issue:

- 1) **Alternative 1: Do Nothing.** Do not add the lighting or receptacles.
- 2) **Alternative 2: Electrical Improvements.** Add lighting and exterior power receptacles at the following locations (and shown on the electrical drawings - Figure STA-ELEC-1-ALT-2 - included in Volume 6 – Appendices, Appendix B):
 - Basin Interior – Add additional basin interior explosion-proof LED lighting fixtures to provide lighting within the basin area to meet operational needs.
 - Outfall area – Add additional lighting at the facility's outfall.
 - Exterior power receptacles are needed on the wall of the facility near the basin to assist in the maintenance and operations of the facility.

The alternative evaluation is presented in Table 14-9. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the lighting is assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.8 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M provided by the added lighting and receptacles. The NPV/Benefit cost for Alternative 2 is \$41,000, which is a relatively low cost compared to other projects recommended in this assessment.

Because of the improved safety with this alternative, Alternative 2 – Electrical Improvements is the recommended alternative.

Table 14-9. Alternative Evaluation for Electrical Improvements (Project STA-ELEC-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	2	2.72	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Less maintenance and energy usage	Capacity Enhancement	3						
	<i>Disadv.:</i>	Less safe	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Electrical Improvements	Health and Safety	4	3.50	\$ 144,000	\$ -	\$ 144,000	\$ 41,143	Not Applicable
	<i>Definition:</i>	Add additional lighting in basin interior and outfall area.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased maintenance and energy usage	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.7 I&C

14.2.7.1 Description of Existing System

Control System: The original control system was installed in 1999 under PC-731. In 2002 the system was upgraded and interfaced into GLWA's overall SCADA Ovation control system. This upgrade provided the ability to remotely monitor the operations of the facility and the local collection system at SCC.

The existing control system contains an Allen Bradley-based PLC system consisting of an Allen Bradley redundant PLC-5 with local I/O controls that are installed in the facility's local control system panel. The operator workstation has a Rockwell RSVIEW operating software platform and is located in the Control Room. The existing hardwired local backup control panel and other miscellaneous subsystems that are incorporated into the overall control system are outdated and need replacement. The control system network and switches are obsolete and do not meet GLWA SCADA Governance standards on redundant networks and switches stipulates and that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a backup radio system to communicate critical monitoring points back to the SCC on wide area network failure.

Flow and Level Sensors: Table 14-10 summarizes the level sensors and flow meters at the St. Aubin CSO Facility for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 14-10. Summary of Flow Meters and Level Sensors at St. Aubin CSO Facility

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent	1	Transit-Time (AccuSonic)
Effluent	1	Transit-Time (AccuSonic)
Toward Treatment Dewatering	1	Magnetic
CSO Level Sensors		
Dubois Diversion Chamber	1	Ultrasonic
Influent Channel	1	Ultrasonic
Mixing Chamber	1	Ultrasonic
Dewatering Chamber	1	Ultrasonic
Effluent Channel	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed	5	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic

14.2.7.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- The outfall level sensor level fluctuates significantly when the levels are high during discharge.

- GLWA staff note that local control of the equipment is needed, including dewatering pumps, flushing valve, and regulator gates) to improve maintenance. (It is noted that remote control of the regulator gates is included under the “Control System Upgrade – St. Aubin, Leib and Seven Mile CSO Facilities” project, so they are not further addressed in this report.)
- Process cameras are needed to observe process performance from the Control Room during a wet weather event
- The control system should be upgraded. GLWA is currently developing an RFP for qualified design-build contractors to provide professional engineering and construction services for control system improvements at the Seven Mile CSO Facility under “Control System Improvements – St. Aubin, Leib and Seven Mile CSO Facilities.” The project will replace the existing PLC-5 control system and backup local control panels with a new control system, provide new Ovation workstations with high-performance graphics, and replace some of the field instruments. This is an ongoing project that has already been included in the CIP.
- The screen graphics are very difficult to understand and should be updated to match other facilities. This improvement is included in the Control System Improvements project described in the previous bullet.

14.2.7.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

I&C Improvements (Project STA-I&C-1). Due to the relatively small nature of some of the I&C related projects identified as improvements, the identified I&C improvements, with the exception of the control system upgrade and simplifying the screen graphics, are proposed to be in one project – I&C Improvements. This project could be split into separate multiple delivery projects, if needed. As such, there are two alternatives for this project:

1) **Alternative 1: Do Nothing**

2) **Alternative 2: I&C Improvements** including,

- Address outfall level sensor fluctuations
- Provide remote control of:
 - Flushing and dewatering pumps at outfall
 - Flushing valve for influent channel
- Provide process cameras at select locations

Each of the I&C related improvements listed above is described further below:

Address outfall level sensor fluctuations. During wet weather, the level sensor signal fluctuates. To remedy, it is recommended to ensure at least 18-in. are clear between the water surface and the level sensor element. Modify the installation, as necessary, to raise the level sensor element to be a minimum of 18 in. above the surface of the highest expected water level. This should be a maintenance issue that gets addressed before this I&C project; however, it is included as a capital improvement in case it is not completed before this project.

Provide remote control of flushing and dewatering pumps at outfall and flushing valve for influent channel. Outfall Flushing and Dewatering Pumps: Provide remote control of the Flushing and Dewatering Pumps at the outfall from the CSO facility. The recommendation is to install a dedicated fiber optic cable from the CSO facility to a control panel located at the outfall.

Influent Channel Flushing Valve: It is recommended to provide remote control of the influent channel flushing valve to allow operations more flexibility when operating the facility during CSO events.

Provide process cameras at select locations. A list of the desired locations for process cameras is included in Section 5.4.8.

The alternative evaluation is presented in Table 14-11. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the remaining improvements in Alternative 2 are difficult to quantify and would not affect the alternative evaluation. Similarly, it is difficult to quantify the monetary benefits of the improved operations through the improved monitoring and control.

This evaluation shows that Alternative 2 – Electrical Improvements has a total benefit score about 0.5 higher than the Do Nothing Alternative (Alternative 1) based on the improved component performance and improved O&M. The NPV/Benefit cost for Alternative 2 is \$67,000, which is a relatively low cost compared to other projects recommended in this assessment. **Because of the improved control and maintainability associated with the I&C improvements, Alternative 2 is the recommended alternative.**

Table 14-11. Alternative Evaluation for I&C Improvements (Project STA-I&C-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.78	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	None	Capacity Enhancement	3						
	<i>Disadv.:</i>	Someone needs to be in Control Room to operate pump remotely during maintenance.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	I&C Improvements	Health and Safety	3	3.32	\$ 170,000	\$ 2,500	\$ 222,724	\$ 67,153	Not Applicable
	<i>Definition:</i>	Add local control to pumps and valves; add process cameras.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved ease of maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Increased instrumentation to maintain.	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.8 Site

14.2.8.1 Description of Existing Site

The St. Aubin facility was constructed in 1999. Access to the site is off of Atwater Street. The access entrance gate is a 25-ft wide sliding vehicular gate. Site security is provided by a 6-ft high security fence around the perimeter of the site. The parking lot consists of 8-in. reinforced concrete pavement with 8-in. crushed limestone base. Concrete sidewalk widths vary from 5 to 14 ft and are approximately 4 in. thick.

The St. Aubin outfall site includes the Sampling Building and access hatch opening to the outfall conduit. The Sampling Building and outfall discharge site are secured by cyclone fencing on all four sides of the site. A 12-ft cantilever sliding gate is located on the west fence line to provide access to the secured area. The secured outfall site is located approximately 340 ft off Atwater Street. A gravel drive extends from Atwater Street to the entrance gate.

Under a separate task of CS-299, all site utilities have been located and included in GLWA's GIS. Site utilities include water, sewer (sanitary, storm and combined sewer), process, natural gas, electric, and communications. The information provided in the GIS includes attributes for each asset type within each utility such as unique identification (ID), name, ownership, horizontal location (coordinates), vertical elevation and depth, utility type, size (diameter, length, dimensions, etc.), material type, the type of surface at the utility (i.e., asphalt, concrete, grass, etc.), installation year, as-built reference drawing number, contract number, section map number, GPS date, and location accuracy.

The information from the GIS is being used to develop the SRP under CS-299 for horizontal assets at all nine CSO facilities. As such, renewal needs related to underground site utilities are not included in this report.

14.2.8.2 Identified Needs and Issues

The needs and issues were identified from meetings with O&M staff and Jacobs team site visit and investigations. These issues are listed below and further described in the next section.

- There are several site issues at the St. Aubin outfall site including: 1) poor drainage in the access drive area between Atwater St. and the fenced area; 2) fencing in disrepair; 3) difficulty in removing hatch plates; and 4) access to the backwater gates. The poor drainage of the access drive has damaged the road surface and has created issues with accessibility to the secured area.
- The concrete surface at the northwest corner of the St. Aubin CSO facility has cracked due to settlement, causing runoff to flow back toward the building.
- At the St. Aubin CSO Control and Headworks Building, are stored in the Odor Control Room or outdoors. There is insufficient space inside the existing building to efficiently store all of the O&M equipment, as well as the equipment to maintain the site, in the main building. A storage building is needed to protect this equipment from ultraviolet light degradation and the elements. This building is currently planned to be installed under a separate project (CIP 260617).
- There are cracks in the sidewalks on the south and east sides of the Control Building.

14.2.8.3 Description and Evaluation of Alternatives

Projects to address the needs and issues identified above are presented in this section. The evaluation of project alternatives is also included in this section along with the recommended alternative.

Outfall Site Improvements (Project STA-Site-1). There are two alternatives to address the issues identified at the St. Aubin outfall:

- 1) **Alternative 1: Do Nothing**
- 2) **Alternative 2: Outfall Site Improvements**

At the outfall site area, which is approximately 340 ft by 75 ft, regrading of the site is included in this alternative to direct the drainage north to the exiting channel to help alleviate poor drainage in this area. Additionally, the gravel drive in this area could be replaced with an alternative design featuring a grass paver surface supported on a new engineered support base. The grass pavers could be for the full width of the access drive, replacing the existing gravel drive. This will also complement the Detroit Riverwalk area in the vicinity. Figure STA-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, shows the location of these issues and suggested improvements.

The cyclone fencing around the site is in disrepair. The fencing includes approximately 400 ft of 8-ft-tall cyclone fencing. The fencing should be replaced to maintain security. Since the facility is located in a city park in a high visibility location, it is suggested that the cyclone fencing on the west, east and south sides of the site be replaced with ornamental fencing. The existing 12-ft wide automatic cantilever sliding gate has experienced numerous recent breakdowns. This equipment has likely reached the end of its useful service life and should be replaced.

The hatch openings over the two outfall backwater gates have dimensions of 8 ft by 10.5 ft. The openings over the two stop log guides are 10.25 ft by 3 ft. The hatch plates over the outfall gate openings are 0.5-in. thick stainless steel plates. These cover plates are very cumbersome to remove due to their weight. It is suggested that the outfall cover plate design be changed to a lighter weight cover plate. The cover plates over the stop log gates are Bilco style hatch covers – these gates should be considered for replacement due to their age.

Accessing the outfall backwater gates and stop logs within the secured fence line can be difficult as the area is all grass surface. It is suggested that the grass paver system identified for the entrance access road to the site be extended within the site so that trucks and equipment can access the outfall structure and gate and stop log hatch openings.

The minor repair to the concrete surface at the facility is included in this project. It is suggested that that this portion of the slab be removed, the subsurface regraded, and the concrete slab replaced to provide proper drainage away from the building.

The alternative evaluation is presented in Table 14-12. The sources of costs used in this evaluation are listed below:

- The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.
- The increased O&M costs for the added features are assumed to be negligible and would not affect the alternative evaluation.

This evaluation shows that Alternative 2 has a total benefit score about 1.0 higher than the Do Nothing Alternative (Alternative 1) based on the improved health and safety and improved O&M. **However, because of the improved accessibility, security and maintenance with the Outfall Site Improvements, Alternative 2 is the recommended alternative.**

Table 14-12. Alternative Evaluation for Outfall Site Improvements (Project STA-SITE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing.	Health and Safety	2	2.50	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do nothing.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lowest cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Site issues remain a concern.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	2						
2	<i>Alt. Name:</i>	Outfall Site Improvements	Health and Safety	4	3.50	\$ 806,000	\$ -	\$ 806,000	\$ 230,286	Not Applicable
	<i>Definition:</i>	Site improvements at the outfall area to address accessibility, security, and ease of maintenance.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved accessibility, security and maintenance.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.9 Architectural

14.2.9.1 Description of Existing Facilities

The St. Aubin CSO facility consists of chemical room, utility support (electrical, emergency generator and mechanical), control room, odor control room and miscellaneous other rooms. The facility has an separate sample building at the end of the outfall.

14.2.9.2 Identified Needs and Issues

The needs and issues for architectural issues were identified by a detailed assessment as described in the following paragraphs.

CS-299 Architectural Assessment. Jacobs conducted an assessment of the architectural-related defects at the CSO facilities. Jacobs used the architectural-related information in NTH's Structural Rehabilitation Needs Assessment (referenced in Section 5.5) for the above-ground buildings as a starting point and included additional items, as observed during the assessments conducted in January 2021 under CS-299. The architectural assessments included:

- Doors
- Windows, including sealant
- Room finishes
- Floors and ceiling coating/covering system
- Stairways
- Corrosion of visible steel members

The architectural assessment did not include structural related defects, such as cracks in walls, spalling concrete, roofs and roofing system, because these items will be accounted for in the on-going Structural Rehabilitation project and the condition of the roofs was assessed recently by NTH. It also does not include assessment of furnishings, such as office furniture, desks, built-in cabinets, audio/video equipment, etc.

Specific O&M Staff Concerns during Facility Assessment Meetings. O&M staff indicated that that additional storage is desired at the St. Aubin facility. Since the meeting, the GLWA Program Management team generated a proposal for a new storage building to be located along the west side of the building, near the existing electrical room. This building is intended to be added during the upcoming capital improvement project (CIP 260617).

14.2.9.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above are presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Architectural Rehabilitation (STA-ARCH-1). Jacobs identified numerous architectural-related defects that should be addressed within the next five years. There are two alternatives to address these issues:

1) Alternative 1: Do Nothing.

2) Alternative 2: Architectural Rehabilitation. Perform the architectural repairs identified under the NTH and CS-299 assessments. The major rehabilitation include the following:

- Remove and replace sealant around doors, windows and other wall penetrations
- Remove and replace sealant at all control/ expansion wall joints
- Remove and replace isolation/ cove joint sealant and around building perimeter

- Remove failed concrete floor coating, clean floor, and reseal floor with chemical resistant coating
- Remove corrosion at bottom of man door and coat steel framing

The detailed list of rehabilitation items are included in the capital cost estimate for this project and are shown in drawings in Volume 6 – Appendices, Appendix B (Figure STA-ARCH-1-ALT-2). Consideration should be given to making some or all of these repairs under the Structural Rehabilitation project.

The alternative evaluation is presented in Table 14-13. The capital costs for Alternative 2 are included in Volume 6 – Appendices, Appendix C under this project title.

Because of the benefit of preventing more costly damage in the future from not addressing these issues, **Alternative 2 is the recommended alternative.**

Table 14-13. Alternative Evaluation for Architectural Rehabilitation (Project STA-ARCH-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Do Nothing	Health and Safety	3	2.90	\$ -	\$ -	\$ -	\$ -	Not Applicable
	<i>Definition:</i>	Do Nothing	Water Quality & Compliance	3						
	<i>Adv.:</i>	Lower cost	Capacity Enhancement	3						
	<i>Disadv.:</i>	Repairs may become more costly in the future.	Component Performance	2						
	<i>Comments:</i>	None	O&M Ease	3						
2	<i>Alt. Name:</i>	Architectural Rehabilitation	Health and Safety	3	3.10	\$ 136,000	\$ -	\$ 136,000	\$ 43,871	Not Applicable
	<i>Definition:</i>	Architectural Rehabilitation	Water Quality & Compliance	3						
	<i>Adv.:</i>	Repairs building defects before they become more severe and costly issues.	Capacity Enhancement	3						
	<i>Disadv.:</i>	Higher cost	Component Performance	4						
	<i>Comments:</i>	None	O&M Ease	3						

14.2.10 Safety

14.2.10.1 Description of Existing System

Safety-related items include fall protection, exit signage, hatch access, and other miscellaneous safety-related issues.

14.2.10.2 Identified Needs and Issues

The safety issues identified during Jacobs Safety Inspection, described in Section 5.7, are listed in Table 14-14. The capital improvement project to address these issues is included in the table.

Table 14-14. Identification of Capital Improvements for Safety Issues

Location	Description	Proposed Corrective Action	Capital Improvement Project
Basin	Seal-off fittings for mixer electrical feed is bypassed (typical of some other mixers also) and open junction box	Incorporate seal-off fitting into electrical wiring.	I&C Improvements
Dewatering Chamber	Exposed power wires in junction box and bypass of explosion-proof seal-off fitting in dewatering pump chamber	Enclose junction box and incorporate seal-off fitting into electrical wiring.	I&C Improvements
Fall Protection	Fall Protection	See Section 5.7.3 and Volume 6 – Appendices, Appendix E	Safety Improvements (Project STA-SAFE-1)

14.2.10.3 Description and Evaluation of Alternatives

A project to address the needs and issues identified above is presented in this section. The evaluation of alternatives is also included in this section, along with the recommended alternative.

Safety Improvements (Project STA-SAFE-1). This project should address the safety issues identified above. These issues include:

- Fall protection

Because the importance of these issues related to safety, it is the only alternative considered. As such, it is the recommended project. For consistency in this report, Table 14-15 shows the one alternative.

Table 14-15. Alternative Evaluation for Safety Improvements (Project STA-SAFE-1)

Alt.	Description		Benefit Category	Benefit Score	Total Benefit	Capital Costs	Annual O&M	NPV	NPV/Benefit (prefer low value)	Best Value Alternative
1	<i>Alt. Name:</i>	Safety Improvements	Health and Safety	5	3.78	\$ 79,000	\$ -	\$ 79,000	\$ 20,881	Best Value Alternative
	<i>Definition:</i>	Safety improvements to address fall protection.	Water Quality & Compliance	3						
	<i>Adv.:</i>	Improved safety for staff and workers.	Capacity Enhancement	3						
	<i>Disadv.:</i>	None.	Component Performance	3						
	<i>Comments:</i>	None	O&M Ease	4						

14.2.11 Supporting Infrastructure

Supporting infrastructure refers to equipment or needs that may not fit into one of the processes or discipline-specific sections above. There were no needs or issues identified related to supporting infrastructure at St. Aubin CSO Facility.

14.2.12 Confirmation of Asset Replacement in Capital Planning

This section includes a review of the CS-299 Asset Assessment to confirm that any assets that requires replacement or rehabilitation are addressed through a capital outlay or capital improvement project.

As described in Section 4, one of the goals of the CS-299 Facilities Assessment is to develop the capital replacement and rehabilitation needs for the assets at each facility. The sections above have evaluated performance enhancement improvement alternatives to address regulatory compliance, safety, or enhance the operability or maintainability of the assets. For recommended alternatives, any assets included in the alternative would be replaced in a CIP project at some time during the expected useful life of the assets.

To ensure that all the assets are being addressed in a capital outlay or improvement project at the St. Aubin CSO facility, Table 14-16 provides a listing of the asset types and the number of assets in each asset type. The table also provides the number of condition assessments (visual or detailed) performed under CS-299 for these assets and the overall percentage of assets that received condition assessments. (The reader is referred to the CS-299 Asset Assessment Report in Volume 3, Section 15 for the results of these assessments.) As shown in the Table 14-16, all of the assets in each asset type were assessed either visually or in detail, with explanation of minor exceptions included in the footnotes. The condition rating and the expected useful life of the assets are used to develop the schedule for replacement of these assets in the SRP.

Table 14-16. Listing of Asset Condition Assessments for St. Aubin Facility

^a One of the building assets listed as "EQUIPMENT - TRAVEL/INSPECTION/TROUBLESHOOT (FOR ELECTRICIANS, MILLWRIGHTS & PLUMBERS ONLY)", which is not an asset.

^b The fire suppression system was assessed independently by Simplex Grinnell and not included in the ACES report.

^c The one gas detector is a portable unit and was not assessed.

^d The one pump not assessed was the Disinfection Sample Pump No. 2, which was inactive.

Jacobs also reviewed all the assets with a condition rating of 3, 4 or 5 for this facility based on the CS-299 Asset Assessment to determine if there were assets that required capital outlay or a capital improvement. Recall, that the intent of the SRP is to develop capital replacement schedules based on asset condition. Therefore, all the assets that were rated in poor condition will be scheduled to be replaced in the near future. Based on the review of the St. Aubin Asset Assessment results, there are no additional capital projects to address the assets in the WAM database.

14.3 Capital Planning for St. Aubin CSO Facility

14.3.1 Summary of Capital Improvement Plan Projects

Table 14-17 provides a summary of the recommended CIP projects and associated capital costs for the St. Aubin CSO facility based on the alternative evaluations conducted for this facility.

Table 14-17. Summary of Recommended Projects at St. Aubin CSO Facility

Project No.	Alternative	Description	Total Project Cost
STA-FD-1	2	New Effluent Conduit Flushing System	\$ 2,472,000
STA-ELEC-1	2	Electrical Improvements	\$ 144,000
STA-I&C-1	2	I&C Improvements	\$ 170,000
STA-I&C-2	1	Control System Upgrade	Ongoing Project
STA-SITE-1	2	Outfall Site Improvements	\$ 806,000
STA-ARCH-1	2	Architectural Rehabilitation	\$ 136,000
STA-SAFE-1	1	Safety Improvements	\$ 79,000

14.3.2 Capital Improvement Project Bundling and Scheduling

Initial bundling of the recommended capital improvement projects for this facility is presented in Table 14-18. The goal of the bundling is to optimize the efficiency of the project delivery by grouping similar discipline work or work in similar areas together, thus optimizing design and construction activities for GLWA operations and engineering staff. A new project title and Project ID are provided for each project. These projects will be rolled up into the overall CIP for the CSO facilities, and may be further bundled with similar projects from other CSO facilities. Some of the recommended capital projects for this facility are recommended to be capital outlay projects, and are presented later in this section.

Table 14-18. Capital Improvement Plan Projects for St. Aubin CSO Facility

Bundled Capital Improvement Project	Total Project Cost (Sum of Individual Projects)	Proposed Year of Construction Completion	Capital Improvement Project		
			Project ID	Project Total	Project Cost
STA-1 Flushing System Improvements	\$ 2,472,000	2028 <i>Timing based on need to clean effluent channel in 10 years from last cleaning in</i>	STA-FD-1	New Effluent Conduit Flushing System	\$2,472,000
STA-2 Facility-Wide Electrical and I&C Improvements	\$ 314,000	2035 <i>Timing based on best judgement</i>	STA-ELEC-1	Electrical Improvements	\$144,000
			STA-I&C-1	I&C Improvements	\$170,000

Unlike the other sections, there are no existing assets in the projects listed above. As such, the Asset Information tables shown for the other facilities are not included here.

14.3.3 20-Year Capital Outlay Plan

Table 14-19 provides a summary of the recommended 20-Year Capital Outlay Plan for this facility, based on SRP results from the CS-299 condition assessment ratings and existing life of the assets, and based on the recognition that the assets included in any CIP project would be replaced as part of that project. Note, the table below is representative of the results based on WAM data available at the time of this report. WAM data is constantly evolving and the SRP model should be used with the most current WAM data set to continuously update results.

RE: Draft Report on Geotechnical Investigation
Great Lakes Water Authority (GLWA)
Design Services for Combined Sewer Outfall (CSO) Improvements Project
GLWA Leib CSO Facility - Contract Number 2101475
Detroit, Michigan

Dear Mr. Khraizat:

We have completed the Draft Report on Geotechnical Investigation for the GLWA Leib CSO Facility Project in the City of Detroit, Michigan. This report presents the results of our observations and results of the geotechnical. The report is draft pending the surveying data at the probe locations and pending your review comments.

The soil samples collected during our field investigation will be retained in our laboratory for 90 days from the date of the final report, at which time these samples will be discarded unless otherwise directed by you.

It was a pleasure working with you on this project. If you have any questions regarding this report, please do not hesitate to contact us 313-963-2721.

Sincerely,
Somat Engineering, Inc.

**DRAFT REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA LEIB CSO FACILITY
DETROIT, MICHIGAN**

REPORT SUMMARY

A general summary of the report conclusions is provided below:

1. The field exploration program consisted of performing a total of 2 soil borings for the GLWA Leib CSO Facility Project in Detroit, Michigan. The borings extended to a depth of 10 feet below existing grades.
2. Generalized soil profile: Fill soils was encountered in boring Leib-02 and extended to a depth of 1.3 feet below existing grades.
3. The long-term groundwater table is estimated to be situated at about 7 feet (EL. XXX) below existing grades. Perched groundwater trapped in the granular fill soils within close proximity of any excavations should also be expected.
4. We recommend undercutting the upper topsoil and underlying granular fill soils to a minimum depth of about 1.5 feet below existing grades and replacing with engineered granular fill soils (such as MDOT 21AA or Class II sand), new base course, and pavement. Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted new engineered fill subgrade soils prepared as noted in this report; should be adequate to support the proposed HS-20 traffic loading for the access drive.

The summary presented above is general in nature and should not be considered apart from the entire text of the report with all the qualifications and considerations mentioned therein. Details of our findings and recommendations are discussed in the following sections and in the appendices of this report.

1.0 INTRODUCTION

1.1 GENERAL

Upon authorization from CDM Smith, Somat Engineering, Inc. (Somat) has completed the geotechnical investigation for the development of the Great Lakes Water Authority (GLWA) Design Services for Combined Sewer Outfall (CSO) Improvements Project at the Leib CSO Facility in the City of Detroit, Wayne County, Michigan.

Somat was retained by CDM Smith to perform a pre-design geotechnical investigation for the referenced project within the project limits. The geotechnical investigation was performed in general accordance with Somat Proposal No. P210314B dated January 12, 2022. The results of the investigation will be used to support the design of the project and development of construction specifications.

1.2 PROJECT INFORMATION

The overall project includes design services required to implement a series of improvements at the Leib CSO Screening and Disinfection (SDF) facility located at 2200 Mt. Elliott, Detroit, Michigan. The site improvements include constructing a new alternate access road shall be about 176 feet long and 24 feet wide, and will require minimal reconfiguration of the existing parking lot.

The following sections of this report provide a description of our field investigation, the results of the field and laboratory tests, the logs of auger probes, our interpretation of subsoil and groundwater conditions, recommendations related to the proposed construction.

2.0 SUBSURFACE INVESTIGATION

2.1 FIELD EXPLORATION

The field exploration program consisted of performing a total of two (2) soil borings. Borings LEIB-01 and LEIB-02 were performed along the grass covered parcel on the east side of the Leib gated facility. The borings extended to a depth of 10 feet below existing grades.

The soil borings were drilled using Geoprobe 3126GT drill rig. The soil borings were drilled by advancing hollow stem augers to the termination depths of the soil borings. Upon completion, all the boreholes were backfilled with soil cuttings to the surface. The soil boring logs are presented as logs of test borings in Appendix B. Soil boring coordinates and the ground surface elevations (included in the soil boring logs) were provided by the Project Surveyor.

2.2 STANDARD PENETRATION TEST

Soil samples collected during the field portion of the subsoil exploration were labeled with the soil boring designation and a unique sample number. Soil samples were obtained from the soil borings by Standard Penetration Tests (SPT) in accordance with ASTM D1586 procedures, whereby a conventional 2-inch O.D. split-spoon sampler is driven into the soil with a 140-pound hammer repeatedly dropped through a free-fall distance of 30 inches. The sampler is generally driven three successive 6-inch increments, with the blows for each 6-inch increment being recorded. The number of blows required to advance the sampler through 12 inches after an initial penetration of 6 inches is termed the Standard Penetration Test resistance (N-value) and is presented graphically on the individual Logs of Test Borings. As added information, the number of blows for each 6-inch increment is also presented on the boring logs.

The N-values reported on the Logs of Test Borings are the direct blow counts from the field and are uncorrected. The efficiency of each specific hammer is dependent on many factors, including type (auto vs. manual), material quality, regularity of maintenance, drill rig mechanics, etc., and can change with time. As such, SPT hammers on each drill rig are required to be calibrated. Certificates are provided to us indicating each hammer's measured energy transfer

ratio. For this project, the geotechnical driller (DLZ American Drilling) used a Geoprobe 3126GT drill rig (serial number: 52110001). Based on the current certificate for this drill rig, the energy transfer ratio for the SPT hammer is 101.3%.

2.3 SAMPLING

Soil boring samples were recovered using split-spoon sampling procedures in accordance with ASTM Standard D1586 (“Standard Method for Penetration Tests and Split Barrel Sampling of Soils”). In general, the samples were obtained continuously to a depth of 5 feet and every 2.5 feet intervals to the termination depth of the borings. The samples were sealed in glass jars in the field to protect the soil and maintain the soil’s natural moisture content.

2.4 GROUNDWATER LEVEL OBSERVATION PROCEDURES

Whenever possible, groundwater level observations were made during the drilling operations and are shown on the individual Logs of Test Borings. During drilling, the depth at which free water was observed, where drill cuttings became saturated or where saturated samples were collected, was indicated as the groundwater level during drilling. In granular, pervious soils, the indicated water levels are considered relatively reliable when solid or hollow-stem augers are used for drilling. However, in cohesive soils, groundwater observations are not necessarily indicative of the static water table due to the low permeability rates of the soils, and due to the sealing off of natural paths of groundwater flow during drilling operations.

It should be noted that seasonal variations and recent precipitation conditions may influence the level of the groundwater table significantly. Groundwater observation wells are generally used if precise groundwater table information is needed, however the installation of groundwater monitoring wells was not included in the scope of the investigation. Therefore, the discussion and recommendations provided within the report are based on our knowledge of the soil and groundwater conditions in this area, as well as the reported design water levels of water bodies located at the bridge locations, which should provide for a reasonable approximation of the groundwater level.

2.5 GEOTECHNICAL LABORATORY TESTING

All soil samples were classified in accordance with the Unified Soil Classification System (USCS). Cohesive soil samples were subjected to laboratory tests consisting of moisture content determinations, and hand penetrometer tests. Loss-on-ignition (LOI) tests are performed on any samples that appear to contain significant organic content.

The results of the soil classifications and the laboratory tests are included on the respective logs in Appendix B. All laboratory tests were performed in accordance with their applicable ASTM procedures.

2.6 LIMITATIONS

The scope of our services was strictly geotechnical and did not include environmental investigation. Our scope of services did not include investigation for the presence or absence of wetlands or hazardous or toxic materials in the soil, surface water, groundwater, or air, on, below or around this site.

Somat has made no observations or recommendations with regard to the presence or absence of mold or other biological contaminants (such as spores, fungi, bacteria, viruses, and the byproducts of such organisms), now or in the future, on this site or within or on any structures to be constructed on this site. Any consideration with regard to the presence of mold, or the possibility of mold growth in or on the structure to be constructed on this site are not within our scope of services on this project.

Some soils have been identified on the Logs of Test Borings as “fill” or “possible fill” if a soil deposit is suspected to have been placed by human activity, versus having been deposited by natural means. These designations were based on our professional engineering judgment considering factors such as our visual classification, the presence of foreign materials (i.e., bricks, concrete, plastic, etc.), and/or site topography, among many other possibilities. As such, the “fill” or “possible fill” descriptions should be considered as secondary information to the standardized soil classification. Due to the large variation of types of fill, methods of fill

placement, potential changes of historical use of the site, and soil sample size, it is difficult to discern whether the subject soil sample is native to this site, or fill material based on visual classification alone. As such, the designation of “fill” may not be reliable and hence should be considered as informational only. Conversely, where a soil is not designated as “fill” on the boring logs, it does not necessarily mean it is not a fill soil, only that there were no apparent observations indicating a fill material. Therefore, we cannot guarantee that our description of “fill” soils is accurate, or that we have identified all types of fill material encountered with our sampling on the site.

3.0 SUBSURFACE CONDITIONS

3.1 SOIL CONDITIONS

Soil conditions encountered at the boring locations have been evaluated and presented in the form of logs of auger probes. The logs of auger probes include approximate soil stratification with detailed soil descriptions and selected physical properties for each stratum encountered in the auger probes. In addition to the observed subsoil stratigraphy, the auger logs present information relating to sample data, groundwater level conditions observed in the probing, personnel involved, and other pertinent data. For information, and to aid in understanding the data as presented on the auger logs, General Notes defining nomenclature used in soil descriptions are presented immediately following the Logs of Test Borings. It should be noted that the Logs of Test Borings included with this report have been prepared on the basis of laboratory classifications and testing as well as field logs of the soils encountered.

A generalized description of the soils and pavement encountered in the six (6) auger probes beginning at the existing ground surface and proceeding downward, is provided below:

Stratum 1: Surface Material:

- **Topsoil:** Clayey topsoil was encountered at the surface of LEIB-01 and 02 and had a thickness of 6 inches.

Stratum 2: Fill Soils:

- **Granular Fill:** Granular fill soils consisting of sand with silt was encountered below the topsoil in boring LEIB-02 and extended to a depth of 1.3 below existing grades. The apparent density of the fill soils was dense.

Stratum 3: Native Cohesive Soils

- Native sandy lean clay was encountered below the topsoil or fill soils in both borings and extended to a depth of 2 to 3.5 feet below existing grades. The consistency of the clay was hard and had a moisture content ranging between 9 and 14%.

Stratum 4: Native Granular Soils

- Native granular soils consisting of sand and silty sand were encountered below the native clays in both borings and extended to the termination depth of 10 feet in boring LEIB-01 and to a depth of 8 feet in boring LEIB-02. The apparent density of the native granular soils ranged between medium dense and very dense.

Stratum 5: Native Cohesive Soils

- Native lean clay was encountered below the native granular soils in boring LEIB-02 and extended to the explored depth of 10 feet below existing grades. The consistency of the clay was very stiff and had a moisture content of 15%.

The logs of soil borings are presented in Appendix B and the soil boring location diagram is presented in Appendix A. It is emphasized that the stratification lines shown on the logs are approximate indications of change from one soil type to another at the locations of the boreholes. The actual transition from one stratum to the next may be gradual and may vary within the area represented by the test boring.

3.2 GROUNDWATER LEVEL OBSERVATIONS

Groundwater was not encountered in boring LEIB-01. Groundwater was encountered at a depth of 7 feet during drilling and 8.5 feet after completion of drilling in boring LEIB-02.

A lack of groundwater in some of the auger holes, does not necessarily mean there is no groundwater in this area, due to the sealing off of natural flow paths during the drilling process. Oftentimes, a change in color from brown to gray in cohesive soils is a good indication of the long-

term groundwater level (indicating oxidation). As such the long-term groundwater table is estimated to be situated at about 7 feet below existing grades (EL. XXX).

Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected.

It should be noted that the elevation of the long-term groundwater table is likely to vary throughout the year depending on the amount of precipitation, runoff, evaporation, and percolation in the area, as well as on the water level in any surface water bodies in the vicinity affecting the groundwater flow pattern.

4.0 GEOTECHNICAL RECOMMENDATIONS

4.1 PROPOSED ACCESS DRIVE

The project includes the construction of a new paved alternate access road that is about 176 feet long and 24 feet wide. The proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

4.1.1 Subgrade Preparation and Groundwater Control Recommendations

Based on the soil borings, the subgrade soils consist of existing granular fill soils over native hard lean clay. We do not recommend constructing new pavement on undocumented fill soils. As such we recommend undercutting the upper topsoil and underlying granular fill soil to a minimum depth of about 1.5 feet below existing grades and replacing with engineered granular fill soils (similar in gradation to MDOT 21AA or Class II sand), new base course, and Portland cement concrete pavement.

Once a rough subgrade has been achieved, the exposed pavement subgrade along the entire sections of access drive to be constructed should be visually checked for the presence of debris, organic matter, and other unsuitable material.

If unsuitable or highly organic subgrade soils (organic contents greater than 4%) are encountered during construction, the material should be assessed by the on-site geotechnical engineer to determine the depth and extent of the material and whether it should be fully undercut.

All of the pavement subgrade areas should be thoroughly proof rolled before placement of the new base course and pavement. The purpose of the proof rolling is to locate overly loose or soft areas as well as to uniformly compact the subgrade surface. In granular soils, proof rolling should be performed with a heavy (minimum 30 ton) self-propelled vibratory roller. Loose or soft areas revealed during compaction or during the proof rolling should either be suitably compacted and aerated if necessary. Any areas that exhibit excessive pumping or yielding should be stabilized, scarified, and re-compacted, if weather conditions permit, or by the removal of the yielding soils and their replacement with engineered fill.

The pavement subgrade will need to be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D-1557 (Modified Proctor). It may be necessary in some areas to undercut unsuitable soils and replace them with a stabilization layer of engineered fill.

The long-term groundwater table is estimated to be situated at a depth of about 7 feet below existing grades (EL. XXX). Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected. We do not expect the excavations required to construct the access drive would extend below the estimated long-term groundwater. As such, we believe the groundwater should be adequately controlled using standard sump pits and pumping methods.

4.1.2 Drainage Considerations

The effects of frost heave are anticipated to be more significant in areas where water is not allowed to drain freely either due to subsoil conditions, site grades, or other factors. We recommend including a new drainage system within the new base course to drain water away from the pavement. The pavement and subgrade will need to be positively graded towards these drainage features or away from the center of the roadway to allow for gravity flow of groundwater.

For all new pavements, final pavement elevations should be designed to provide positive surface drainage. The minimum surface slope of 2 percent is recommended. The pavement surface should be smooth, free of roller marks or depressions, and should not contain any irregularities which would pond or impede water flow

4.1.3 Pavement Design Recommendations

4.1.3.1 Subgrade Design Values

We anticipate the subgrade soils for the proposed pavement construction will consist of existing fill soils. The recommended subgrade resilient modulus (M_R) and vertical subgrade reaction (K_v) provided below assumes the soil conditions encountered in the auger probes are representative of the soil conditions within the proposed pavement construction areas. This also assumes the recommended earthwork operations will have been incorporated into the project specifications and that the subgrade soils will have been compacted. If during construction, the subgrade is found to vary from the expected soil conditions, we should be contacted so we may re-evaluate our soil design parameters.

For Portland cement concrete pavement design, based on our experience with similar soil conditions and the results of the in-situ SPT tests, we recommend the following coefficients of subgrade reaction (K_v), subgrade resilient moduli (M_R), and CBR's be used as representation for the conditions of the soils at the new base course and subgrade levels compacted to project specifications.

Table 4.1.3.1 Recommended Pavement Subgrade Design Parameters

Soil Type	Coefficient of Vertical Subgrade Reaction, (K_v)	Subgrade Resilient Moduli (M_R)	CBR
Existing Native Clay Soils	85 pci	6,000 psi	4
New Engineered Sand Fill (MDOT Class II)	235 pci	22,500 psi	15
New Engineered Aggregate Base (MDOT 21AA)	340 pci	37,500 psi	25

Other factors should also be considered in the final pavement design, in addition to the subgrade modulus values. These factors may include, but are not limited to, adequate subgrade preparation, adequate placement of engineered fill and pavement layers, and surface and subsurface drainage.

4.1.3.2 Pavement Section Design Recommendations

As we understand, the proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

We performed pavement analysis utilizing the AASHTO 1993 Guide for Design of Pavement Structures and the associated design charts and nomographs. The following list summarizes our input parameters and assumptions based on AASHTO guidelines and our observations:

Pavement Design Life	20 years (7 days per week)
Loading	HS-20 (8,000 lb/ front axle and two 32,000 lb/ rear axles (Given)
Load Equivalent Factor (LEF)	2.985 (calculated based on HS-20 loading using AASHTO LEF tables for terminal serviceability of 2.5)
Maximum Average Daily Traffic (ADT)	185 vehicles per day with HS-20 loading criteria (Back calculated)
Maximum Design ESAL's:	4,000,000 ESAL (Back calculated)
Percent Trucks:	100 %

Reliability:	90 % (Arterial road)
Standard Deviation:	0.35 (Rigid pavement)
Drainage Coefficient:	1.0
Initial Serviceability:	4.5 (Rigid pavement)
Terminal Serviceability:	2.5 (Major collectors)
Growth Rate	3%
Load Transfer Coefficient	2.7 (Dowel and mesh)
Concrete Elastic Modulus	6,000,000 psi (Assumed)
Effective Modulus of Subgrade Reaction of new base course (MDOT 21AA)	340 pci (CBR =25)
Effective Modulus of Subgrade Reaction of clay subgrade	85 pci (CBR =4)
Mean Concrete Modulus of Rapture	650 psi

Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted existing granular fill soils prepared as noted in this report; should be adequate to support the proposed traffic loading for the access drive.

5.0 GENERAL QUALIFICATIONS

All construction activities should be monitored under the direction of a qualified Geotechnical Engineer to verify conditions as interpreted in this report. This report and the attached Logs of Soil Borings are instruments of service, which have been prepared in accordance with generally accepted soil and foundation engineering practices. We make no other warranties either expressed or implied as to the professional advice included in this report.

The contents of this report have been selected in order to aid in the evaluation of expected subsoil properties to assist the Engineer in the design of this project. In the event that any changes are made in the geotechnical aspects of this project, however slight, the conclusions and recommendations contained in this report shall not be considered valid unless the changes are reviewed, and the conclusions of this report are modified in writing by our office.

Since the information obtained from auger probes is specific to the exact test locations, soil and water information could be different from those occurring at other locations of the site. This report does not reflect variations which may occur between the test holes. The nature and extent of these variations may not become evident until the time of construction. If significant variations then become evident, it may be necessary for us to re-evaluate the recommendations provided in this report.

This report and the associated soil logs should be made available to bidders prior to submitting their proposals and to the successful Contractor and subcontractors for their information only, and to supply them with facts relative to the subsurface investigation, laboratory tests, etc.

The discussions and recommendations submitted in this report are based on the soil information contained in the Logs of Soil Borings and test results appended to this report. We expect that the logs of auger probes, test results, and the soil profiles included in this report along with our discussions and conclusions will assist you in designing the proposed pavement. Please refer to Appendix C for important information about this geotechnical investigation report. If you have any questions regarding this report, please contact us.

Detroit, Michigan

SOIL EROSION AND SEDIMENTATION CONTROL GENERAL NOTES AND REQUIREMENTS:

1. CONTRACTOR SHALL NOTIFY THE WAYNE COUNTY SOIL EROSION OFFICE 48 HOURS BEFORE WORK IS TO BEGIN AT 734-326-3936.
2. ALL SOIL EROSION AND SEDIMENTATION CONTROL WORK SHALL CONFORM TO THE STANDARDS AND SPECIFICATIONS OF WAYNE COUNTY. THE CONTRACTOR SHALL OBTAIN THE SOIL EROSION CONTROL PERMIT FROM WAYNE COUNTY, AND SHALL MAINTAIN COMPLIANCE WITH THE PERMIT THROUGHOUT CONSTRUCTION.
3. CONTRACTOR SHALL PROVIDE A DETAILED SCHEDULE SHOWING DATES AND DURATION FOR EACH PHASE OF EARTH DISTURBANCE TO THE WAYNE COUNTY SOIL EROSION OFFICE FOR APPROVAL.
4. EROSION AND ANY SEDIMENT FROM WORK ON THIS SITE SHALL BE CONTAINED ON THE SITE AND NOT ALLOWED TO COLLECT ON ANY OFF-SITE AREAS OR IN WATERWAYS. WATERWAYS INCLUDE BOTH NATURAL AND MAN-MADE OPEN DITCHES, STREAMS, STORM DRAINS, LAKES, AND PONDS.
5. CONTRACTOR SHALL PROVIDE AND INSTALL SOIL EROSION AND SEDIMENTATION CONTROL (SESC) DEVICES, AS SHOWN, BEFORE PROCEEDING WITH ANY OTHER SITE WORK. CONTRACTOR SHALL MAINTAIN ALL SESC DEVICES FOR THE DURATION OF THE CONSTRUCTION. AT THE END OF CONSTRUCTION, CONTRACTOR SHALL RESTORE ALL DISTURBED AREAS. ONCE GRASS IS ESTABLISHED, CONTRACTOR SHALL REMOVE AND DISPOSE OF ALL TEMPORARY SESC DEVICES AND COLLECTED DEBRIS. TEMPORARY CONTROLS SHALL BE REMOVED ONLY AFTER GETTING APPROVAL BY THE WAYNE COUNTY SOIL EROSION INSPECTOR.
6. CONTRACTOR SHALL INSPECT AND MAINTAIN SESC DEVICES ON A WEEKLY BASIS AND WITHIN 24 HOURS AFTER A STORM EVENT. THE CONTRACTOR SHALL REMOVE ACCUMULATED DEBRIS AND MAKE NECESSARY REPAIRS AS-DIRECTED BY THE ENGINEER.
7. CONTRACTOR IS TO MAINTAIN DRAINAGE OF THE SITE FOR THE DURATION OF CONSTRUCTION. DRAINAGE MATERIALS AND COLLECTED DEBRIS ARE REMOVED AT THE END OF CONSTRUCTION AND THE AREA RESTORED. ALL EXCESS EXCAVATED MATERIALS SHALL BE REMOVED FROM THE SITE AND DISPOSED OF PROPERLY. OWNER SHALL BE INFORMED OF THE DISPOSAL AREA(S), PRIOR TO ANY MATERIALS LEAVING THE SITE.
8. ALL STORM SEWERS USED TO CONVEY DISCHARGES FROM EXCAVATION DE-WATERING SYSTEMS SHALL BE FLUSHED AND CLEANED.
9. CONTRACTOR SHALL SWEEP ROADWAYS AT LEAST ONCE PER DAY OF EACH WORKDAY THROUGHOUT THE PROJECT WHILE EARLY CONSTRUCTION IS IN PROGRESS. ANY MUD/DIRT TRACKED ONTO EXISTING CITY/COUNTY/STATE ROAD SHALL BE PROMPTLY REMOVED BY THE CONTRACTOR. THIS WORK SHALL BE INCLUDED IN THE UNIT BID COSTS FOR SESC.
10. CONTRACTOR SHALL MAINTAIN SAFE, DUST FREE CONDITION ON EXISTING STREETS WHICH SHALL REQUIRE DAILY REMOVAL OF EARTH TRACKED OR SPILLED ON ROAD SURFACE, AND OTHER DUST CONTROL MEASURES AS REQUIRED BY THE PROJECT ENGINEER. EXCESSIVE DUST WILL NOT BE TOLERATED AT ANY TIME DURING CONSTRUCTION. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.
11. WHEN THE SITE IS READY FOR FINAL GRADING, RE-GRADE THE SITE AND COMPLETE ALL PAVEMENT WORK, THEN PERMANENTLY STABILIZE THE SITE PER CONTRACT REQUIREMENTS BY SEEDING.
12. PERMANENT SOIL EROSION AND SEDIMENTATION CONTROL MEASURES FOR ALL SLOPES, CHANNELS, DITCHES, OR ANY DISTURBED LAND AREA SHALL BE COMPLETED WITHIN 5 CALENDAR DAYS AFTER FINAL GRADING OR THE FINAL EARTH CHANGE HAS BEEN COMPLETED. WHEN IT IS NOT POSSIBLE TO PERMANENTLY STABILIZE A DISTURBED AREA AFTER AN EARTH CHANGE HAS BEEN COMPLETED OR WHERE SIGNIFICANT EARTH CHANGE ACTIVITY CEASES, TEMPORARY SOIL EROSION AND SEDIMENTATION CONTROL MEASURES SHALL BE IMPLEMENTED WITHIN 30 CALENDAR DAYS. ALL TEMPORARY SOIL EROSION AND SEDIMENTATION CONTROL MEASURES SHALL BE MAINTAINED UNTIL PERMANENT SOIL EROSION AND SEDIMENTATION CONTROL MEASURES ARE IMPLEMENTED.
13. DITCHES, GULLIES, AND OTHER AREAS THAT WILL CHANNEL CONCENTRATED RUNOFF MUST BE STABILIZED.

REMOVAL LEGEND

	REMOVE SIDEWALK
	REMOVE BRICK PAVERS
	REMOVE FENCE
	REMOVE CONCRETE PAVEMENT
	REMOVE ASPHALT
	CSO BASIN LIMITS

PLAN NOTES:

1. REFER TO SME ALTA SURVEY PLAN SHEET 2-LEIB FOR EXISTING ONSITE STORM SEWER INFORMATION.
2. EXISTING SITE INFORMATION NOT FOUND ON THIS SHEET CAN BE FOUND IN ALTA SURVEY PLAN SHEETS 2-LEIB AND 3-LEIB.
3. THE CONTRACTOR SHALL CONFINE ALL CONSTRUCTION OPERATIONS TO THE STAGING AREAS SHOWN ON THIS SHEET.
4. THE EXISTING UNDERGROUND CSO BASIN LIMITS ARE SHOWN ON THIS SHEET. MAXIMUM LOAD LIMIT ON THE BASIN TOP SLAB IS 300 PSF. THIS INCLUDES COMBINATIONS OF LOADS AT ANY ONE POINT IN TIME- EQUIPMENT, SOIL, ETC. THE CONTRACTOR IS RESPONSIBLE FOR THE EVALUATION OF THE EFFECTS OF ALL LOADS DUE TO CONSTRUCTION-RELATED ACTIVITIES ON THE BASIN AND OTHER EXISTING STRUCTURES ON THE SITE. SEE STRUCTURAL CAPACITY EVALUATION SPECIAL PROVISION FOR REQUIREMENTS.
5. SITE MUST BE SECURE AT THE END OF EACH WORK DAY. CONTRACTOR SHALL ONLY REMOVE AS MUCH FENCE AS HE CAN REPLACE THAT DAY. TEMPORARY FENCE SHALL MATCH OR EXCEED EXISTING FENCE.
6. UNDAMAGED BRICK PAVERS ARE TO BE SALVAGED WHERE POSSIBLE. DAMAGED BRICK PAVERS ARE TO BE REPLACED.
7. CONTRACTOR SHALL NOT EXERT ANY LOAD ON CONCRETE AREA INCLUDING ANY EQUIPMENT, DEBRIS, DIRT, ETC.

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2488 (Modified)

DRILLING & SAMPLING SYMBOLS:

SS:	Split Spoon – 1 3/8" I.D., 2" O.D. (standard)	BS:	Bulk Sample	RC:	Rock Core with diamond bit, NX size, (unless otherwise noted)
S:	Split Spoon – non-standard size, as noted	HSA:	Hollow Stem Auger	RB:	Rock Bit/Roller Bit
ST:	Thin-Walled Tube – 3" O.D., (unless otherwise noted)	DP:	Direct Push	WR:	Wash Rotary
LS:	Liner Sample	PS:	Piston Sample	NR:	No Recovery
PA:	Power Auger	PT:	Pitcher Sample	VS:	Vane Shear Test
HA:	Hand Auger	WS:	Wash Sample	ER:	Hammer Energy Ratio
AU:	Auger Sample				

Standard Penetration Test Resistance, N-Value: Sum of 2nd and 3rd 6-inch increments, in blows per foot of a 140-pound hammer falling 30 inches and driving an 18-inch to 30-inch long, 2-inch OD split spoon.

WATER LEVEL MEASUREMENT:

Water levels indicated on the boring logs are the levels measured in the borings at the times indicated. In pervious soils, the indicated levels may reflect the location of a groundwater table. In low permeability soils (clays and silts), the accurate determination of groundwater levels may not be possible with only short-term observations. Groundwater levels at times and locations other than when and where individual borings were performed could vary.

DESCRIPTIVE SOIL CLASSIFICATION:

Soil classification is based on the Unified Soil Classification (USC) System and ASTM Standards D-2487 and D-2488. Coarse-grained soils have more than 50% of their dry weight retained on a #200 sieve; they are described as: gravel or sand. Fine-grained soils have less than 50% of their dry weight retained on a #200 sieve; they are generally described as: clays, if they are plastic, and silts, if they are slightly plastic or non-plastic. Major constituents may be added as modifiers and minor constituents may be added according to the relative proportions based on grain size. In addition to gradation, coarse-grained soils are defined on the basis of their apparent in-place density and fine-grained soils on the basis of their apparent in-place density (silty soils) or consistency (clayey soils).

CONSISTENCIES OF COHESIVE SOILS:

The pocket penetrometer, pocket torvane, and in-situ vane shear tests are converted into an estimated unconfined compressive strength, in pounds per square feet (psf), for presentation on the logs. The unconfined compressive strength is estimated to be about two times the shear strength.

DESCRIPTORS OF MINOR CONSTITUENTS

Primary Constituent	Fine-Grained (Silt & Clay)	Coarse-Grained (Sand & Gravel)	
Descriptor of Other Constituents	Relative Portion of Coarse Grained Soils as a % of Dry Weight	Relative Portion of Fine Grained Soils as a % of Dry Weight	Relative Portion of Coarse Grained Soils as a % of Dry Weight
Trace	<5%	<5%	<5%
Few	≥5% - <15%	N/A	≥5% - <15%
With	≥15% - <30%	≥5% - 12%	≥15%
Modifier	≥30%	>12%	N/A

FINE-GRAINED SOILS

Unconfined Compressive Strength Q_u , psf	Consistency	N-Value	Apparent Density
< 500	Very Soft	0 – 4	Very Loose
500 - <1,000	Soft	5 – 9	Loose
1,000 - <2,000	Medium	10 – 29	Medium Dense
2,000 - <4,000	Stiff	30 – 49	Dense
4,000 - <8,000	Very Stiff	50 – 80	Very Dense
≥ 8,000	Hard	>80	Extremely Dense

COARSE-GRAINED SOILS

DEFINITIONS OF STRUCTURAL AND DEPOSITIONAL FEATURES

Term	Definition
Parting	≤ 1/16 inch (1.6 mm) thick
Seam	> 1/16 inch (1.6 mm) → 1/2 inch (12.7 mm) thick
Layer	> 1/2 inch (12.7 mm) to ≤ 12 inches (305 mm) thick
Pocket	Small, erratic deposits of limited lateral extent
Lens	Lenticular deposit
Lensed	Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay
Varved	Alternating partings or seams (1 mm – 12 mm) of silt and/or clay and sometimes fine sand
Stratified	Alternating layers of varying material or color with layers ≥ 6 mm thick
Laminated	Alternating layers of varying material or color with layers < 6 mm thick
Fissured	Contains shears or separations along planes of weakness
Slickensided	Shear planes appear polished or glossy, sometimes striated
Blocky	Cohesive soil that can be broken down into small angular lumps which resist further breakdown
Homogeneous	Same color and appearance throughout
Occasional	One or less per foot (305 mm) of thickness
Frequent	More than one per foot (305 mm) of thickness
Interbedded	Applied to strata of soil lying between or alternating with other strata of a different nature

DEFINITIONS OF PAVEMENT CONDITION

Condition	Description
Good	ACC Very slight or no raveling, surface shows some traffic wear. Longitudinal cracks and transverse cracks (open 1/4 inch). No patching or very few patches in excellent condition.
	PCC Moderate scaling in several locations. A few isolated surface spalls. Shallow reinforcement causing cracks. Several corner cracks, tight or well sealed. Open (1/4 inch wide) longitudinal or transverse joints.
Fair	ACC Severe surface raveling. Multiple longitudinal and transverse cracking with slight raveling. Longitudinal cracking in wheel path. Block cracking (over 50% of surface). Patching in fair condition. Slight rutting or distortions (1/2 inch deep or less).
	PCC Severe polishing, scaling, map cracking, or spalling over 50% of the area. Joints and cracks show moderate to severe spalling. Pumping and faulting of joints (1/2 inch with fair ride). Several slabs have multiple transverse or meander cracks with moderate spalling.
Poor	ACC Alligator cracking (over 25% of surface). Severe distortions (over 2 inches deep) Extensive patching in poor condition. Potholes.
	PCC Extensive slab cracking, severely spalled and patched. Joints failed. Patching in very poor condition. Severe and extensive settlement or frost heaves.

GRAIN SIZE TERMINOLOGY

Major Component of Sample	Size Range
Boulders	≥ 12" (300 mm)
Cobbles	< 12" - 3" (300 mm – 75 mm)
Gravel - Coarse	< 3" - 3/4" (75 mm – 19 mm)
Gravel - Fine	< 3/4" - #4 (19 mm – 4.75 mm)
Sand - Coarse	< #4 - #10 (4.75 mm – 2 mm)
Sand - Medium	< #10 - #40 (2 mm - 0.425 mm)
Sand - Fine	< #40 - #200 (0.425 mm - 0.074 mm)
Silt	< 0.074 mm - 0.005 mm
Clay	< 0.005 mm

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2487

Criteria for Assigning Group Symbols and Group Names Using Laboratory Tests ^A				Soil Classification	
				Group Symbol	Group Name <i>B</i>
COARSE-GRAINED More than 50 % retained on No. 200 sieve	Gravels (More than 50 % of coarse fraction retained on No. 4 sieve)	Clean Gravels	$Cu \geq 4$ and $1 \leq Cc \leq 3^D$	GW	Well-graded gravel ^E
		(Less than 5% fines ^C)	$Cu < 4$ and/or $[Cc < 1 \text{ or } Cc > 3]^D$	GP	Poorly graded gravel ^E
		Gravels with Fines	Fines classify as ML or MH	GM	Silty gravel ^{E,F,G}
		(More than 12 % fines ^C)	Fines classify as CL or CH	GC	Clayey gravel ^{E,F,G}
	Sands (50 % or more of coarse fraction passes No. 4 sieve)	Clean Sands	$Cu \geq 6$ and $1 \leq Cc \leq 3^D$	SW	Well-graded sand ^I
		(Less than 5 % fines ^H)	$Cu < 6$ and/or $[Cc < 1 \text{ or } Cc > 3]^D$	SP	Poorly graded sand ^I
		Sands with Fines	Fines classify as ML or MH	SM	Silty sand ^{F,G,I}
		(More than 12 % fines ^H)	Fines classify as CL or CH	SC	Clayey sand ^{F,G,I}
FINE-GRAINED SOILS 50 % or more passes the No. 200 sieve	Silts and Clays Liquid limit less than 50	inorganic	PI > 7 and plots on or above "A" line ^J	CL	Lean clay ^{K,L,M}
			PI < 4 or plots below "A" line ^J	ML	Silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OL	Organic clay ^{K,L,M,N}
					Organic silt ^{K,L,M,O}
	Silts and Clays Liquid limit more than 50	inorganic	PI plots on or above "A" line	CH	Fat clay ^{K,L,M}
			PI plots below "A" line	MH	Elastic silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OH	Organic clay ^{K,L,M,P}
					Organic silt ^{K,L,M,Q}
HIGHLY ORGANIC SOILS	Primarily organic matter, dark in color, and organic odor			Pt	Peat
^A Based on the material passing the 3-in. (75-mm) sieve. ^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name. ^C Gravels with 5 to 12 % fines require dual symbols: GW-GM well-graded gravel with silt GW-GC well-graded gravel with clay GP-GM poorly graded gravel with silt GP-GC poorly graded gravel with clay ^D $Cu = D_{60}/D_{10}$ $Cc = (D_{30})^2 / (D_{10} \times D_{60})$ ^E If soil contains ≥ 15 % sand, add "with sand" to group name. ^F If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM. ^G If fines are organic, add "with organic fines" to group name.				^H Sands with 5 to 12 % fines require dual symbols: SW-SM well-graded sand with silt SW-SC well-graded sand with clay SP-SM poorly graded sand with silt SP-SC poorly graded sand with clay ^I If soil contains ≥ 15 % gravel, add "with gravel" to group name. ^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay. ^K If soil contains 15 to <30 % plus No. 200, add "with sand" or "with gravel," whichever is predominant. ^L If soil contains ≥ 30 % plus No. 200, predominantly sand, add "sandy" to group name. ^M If soil contains ≥ 30 % plus No. 200, predominantly gravel, add "gravelly" to group name. ^N $PI \geq 4$ and plots on or above "A" line. ^O $PI < 4$ or plots below "A" line. ^P PI plots on or above "A" line. ^Q PI plots below "A" line.	

Order of Classification: 1) Consistency or Apparent Density, 2) Type of Soil, 3) Minor Soil Type(s), 4) Inclusions, 5) Layered Soils, 6) Color, 7) Water Content, 8) USCS Symbol, 9) Geological Name

Description of Frequently Used Laboratory Testing Procedures

Visual Engineering Classification

Visual classification was performed on all samples (though other means of refining the classification may also be used). The General Notes provided immediately following the Logs of Test Borings include a brief discussion of the general method used to visually classify the soil, which is based on the visual-manual procedure (ASTM D2488). The visual classification is used to assign an appropriate Unified Soil Classification System (USCS) group symbol. The USCS symbol is shown in parentheses following the textural description of the various strata on the boring logs.

Where more laboratory testing is performed (requiring both grain size and Atterberg limit tests), the classification may also be refined further based on USCS ASTM D2487.

Moisture Content (ASTM D2216)

Moisture content determination tests were performed in accordance with ASTM D2216. Samples were sealed in the field to retain the natural moisture content of the soil specimen. Samples were then dried at a constant temperature (approximately 110° C) overnight in an oven. After drying, the samples were weighed to determine the dry weight of the sample (and the loss in weight representing the water contained in the original sample). The moisture content of the specimen is expressed as a percent and is the weight of the water compared to the dry weight of the specimen.

Hand Penetrometer

A hand/pocket penetrometer was used to estimate the unconfined compressive strength of cohesive (clay) samples. In the hand penetrometer test, the shear strength of a cohesive soil sample is estimated by measuring the resistance of the sample to the penetration of a small, calibrated spring-loaded cylinder. The maximum capacity of the penetrometer is 4.5 tons per square foot. The shear strength is doubled and reported on the soil boring logs as an estimate of the unconfined compressive strength.

Grain Size Analyses (ASTM D6913, D7928, and/or D422-2017)

Grain size analyses were performed in accordance with ASTM D6913, D7928, and/or D422-2017 on selected soil samples to evaluate the gradation of the soil represented by the sample. The distribution of particle sizes larger than 75 micrometers (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 75 micrometers is determined by a sedimentation process using a hydrometer.

Atterberg Limits Tests (ASTM D4318)

Determination of the Liquid Limit, Plastic Limit, and Plasticity Index of cohesive soils (known as Atterberg Limits) were performed in accordance with ASTM D4318. Fine-grained soils are tested to determine the Liquid Limit (LL) and Plastic Limits (PL), which are moisture contents that define boundaries between material consistency states. The LL and PL values define the transitional boundaries between non-plastic, plastic, and viscous fluid states. The plasticity index (PI) defines the complete range in water content for the plastic state.

Description of Frequently Used Laboratory Testing Procedures (continued)

Organic Content (Loss-On-Ignition) Tests (ASTM D7348)

The organic content of a soil is determined through a Loss-On-Ignition test performed in accordance with ASTM D2974 on soil samples suspected to contain significant organics. After the sample has been oven-dried, the soil sample is super-heated in a 440°C muffle furnace as a means to burn off all present organic matter. The weight of the remaining ash is used to calculate the percentage of organic matter as compared to the dry weight of the sample.

APPENDIX F

GEO-PROFESSIONAL BUSINESS ASSOCIATION (GBA) MESSAGE

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, you can benefit from a lowered exposure to problems associated with subsurface conditions at project sites and development of them that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed herein, contact your GBA-member geotechnical engineer. Active engagement in GBA exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Understand the Geotechnical-Engineering Services Provided for this Report

Geotechnical-engineering services typically include the planning, collection, interpretation, and analysis of exploratory data from widely spaced borings and/or test pits. Field data are combined with results from laboratory tests of soil and rock samples obtained from field exploration (if applicable), observations made during site reconnaissance, and historical information to form one or more models of the expected subsurface conditions beneath the site. Local geology and alterations of the site surface and subsurface by previous and proposed construction are also important considerations. Geotechnical engineers apply their engineering training, experience, and judgment to adapt the requirements of the prospective project to the subsurface model(s). Estimates are made of the subsurface conditions that will likely be exposed during construction as well as the expected performance of foundations and other structures being planned and/or affected by construction activities.

The culmination of these geotechnical-engineering services is typically a geotechnical-engineering report providing the data obtained, a discussion of the subsurface model(s), the engineering and geologic engineering assessments and analyses made, and the recommendations developed to satisfy the given requirements of the project. These reports may be titled investigations, explorations, studies, assessments, or evaluations. Regardless of the title used, the geotechnical-engineering report is an engineering interpretation of the subsurface conditions within the context of the project and does not represent a close examination, systematic inquiry, or thorough investigation of all site and subsurface conditions.

Geotechnical-Engineering Services are Performed for Specific Purposes, Persons, and Projects, and At Specific Times

Geotechnical engineers structure their services to meet the specific needs, goals, and risk management preferences of their clients. A geotechnical-engineering study conducted for a given civil engineer

will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client.

Likewise, geotechnical-engineering services are performed for a specific project and purpose. For example, it is unlikely that a geotechnical-engineering study for a refrigerated warehouse will be the same as one prepared for a parking garage; and a few borings drilled during a preliminary study to evaluate site feasibility will not be adequate to develop geotechnical design recommendations for the project.

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project or purpose;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, the reliability of a geotechnical-engineering report can be affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying the recommendations in it. A minor amount of additional testing or analysis after the passage of time – if any is required at all – could prevent major problems.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read the report in its entirety. Do not rely on an executive summary. Do not read selective elements only. *Read and refer to the report in full.*

You Need to Inform Your Geotechnical Engineer About Change

Your geotechnical engineer considered unique, project-specific factors when developing the scope of study behind this report and developing the confirmation-dependent recommendations the report conveys. Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the elevation, configuration, location, orientation, function or weight of the proposed structure and the desired performance criteria;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project or site changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept*

responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

Most of the “Findings” Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site’s subsurface using various sampling and testing procedures. *Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing is performed.* The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgement to form opinions about subsurface conditions throughout the site. Actual site-wide subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team through project completion to obtain informed guidance quickly, whenever needed.

This Report’s Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgement and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* exposed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals’ misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a continuing member of the design team, to:

- confer with other design-team members;
- help develop specifications;
- review pertinent elements of other design professionals’ plans and specifications; and
- be available whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction-phase observations.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note*

conspicuously that you’ve included the material for information purposes only. To avoid misunderstanding, you may also want to note that “informational purposes” means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. This happens in part because soil and rock on project sites are typically heterogeneous and not manufactured materials with well-defined engineering properties like steel and concrete. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled “limitations,” many of these provisions indicate where geotechnical engineers’ responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a “phase-one” or “phase-two” environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually provide environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures.* If you have not obtained your own environmental information about the project site, ask your geotechnical consultant for a recommendation on how to find environmental risk-management guidance.

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, the engineer’s services were not designed, conducted, or intended to prevent migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, *proper implementation of the geotechnical engineer’s recommendations will not of itself be sufficient to prevent moisture infiltration.* Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. *Geotechnical engineers are not building-envelope or mold specialists.*

RE: Draft Report on Geotechnical Investigation
Great Lakes Water Authority (GLWA)
Design Services for Combined Sewer Outfall (CSO) Improvements Project
GLWA Oakwood CSO Facility - Contract Number 2101475
Detroit, Michigan

Dear Mr. Khraizat:

We have completed the Draft Report on Geotechnical Investigation for the GLWA Oakwood CSO Facility Project in the City of Detroit, Michigan. This report presents the results of our observations and results of the geotechnical. The report is draft pending the surveying data at the probe locations and pending your review comments.

The soil samples collected during our field investigation will be retained in our laboratory for 90 days from the date of the final report, at which time these samples will be discarded unless otherwise directed by you.

It was a pleasure working with you on this project. If you have any questions regarding this report, please do not hesitate to contact us 313-963-2721.

Sincerely,
Somat Engineering, Inc.

**DRAFT REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

REPORT SUMMARY

A general summary of the report conclusions is provided below:

1. The field exploration program consisted of performing a total of 6 hand auger probes for the GLWA Oakwood CSO Facility Project in Detroit, Michigan. The auger probes extended to depths ranging between 5 and 6 feet below existing grades.
2. Generalized soil profile: Fill soils were encountered in 4 of the 6 auger probes and extended to depths ranging between 2 and 5.5 feet below existing grades. The fill soils generally consisted of roadway gravel and granular soils. Native soils consisting of lean clay or sandy lean clay were encountered below the fill or below the topsoil and extended to the exploration depths of the borings. The consistency of the native clays was stiff to very stiff and the moisture content ranged between 15 and 45%.
3. Groundwater was not encountered during augering or upon completion of augers in any of the hand auger probes. Based on the change from brown to gray in the cohesive soils of OAK-04 and 06, the long-term groundwater table is estimated to be situated at about 3.3 to 4 feet (EL. XXX) below existing grades. Perched groundwater trapped in the granular fill soils within close proximity of any excavations should also be expected.
4. The gravel service road will be replaced with new reinforced concrete pavement that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. The current pavement design calls for a total length of about 1,000 lineal feet and a width of 16 feet. The proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base (MDOT 21AA gradation) designed to support HS-20 loading.
5. The existing gravel road consisted of 10 to 18 inches of crushed aggregate with silty sand over granular fill soils. The fines content of the existing gravel road material ranged between 11 and 25% which is higher than the allowable limit of fines content of MDOT 21AA aggregate. The excessive fines in the base course will reduce the permeability of the base and increase its susceptibility to detrimental frost action. As such, we recommend removal and replacement with new clean and compacted aggregate base material. Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted existing granular fill subgrade soils prepared as noted in this report; should be adequate to support the proposed HS-20 traffic loading for the service drive.
6. A total of 3 auger probes were performed within the existing bioswale located on the west side of the basin. The general soil profile consisted of topsoil over granular fill soils over native clays. The layer of the granular fill soils consisted of clayey sand and ranged in

**DRAFT REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

thickness between 4 and 18 inches. These fill soils had 43% of fines (silt and clay) which is considered elevated and will not promote positive drainage. Based on the in-situ falling head permeability tests performed at a depth of 4 to 6 feet below existing grades, the mean hydraulic conductivity of the existing native clay soils ranged between 0.007 and 0.025 inch/hour which is considered almost impermeable. For the proposed bioswale, we recommend undercutting the existing fill and some of the native clay soils and replacing with drainable engineered fill with gradation in accordance with the GSI design specifications. The width, length, and depth of the proposed bioswale will be designed by others to accommodate the anticipated volume surface water surface runoff during the wet seasons, and taking into consideration the anticipated long-term groundwater table at the site.

The summary presented above is general in nature and should not be considered apart from the entire text of the report with all the qualifications and considerations mentioned therein. Details of our findings and recommendations are discussed in the following sections and in the appendices of this report.

**DRAFT REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

1.0 INTRODUCTION

1.1 GENERAL

Upon authorization from CDM Smith, Somat Engineering, Inc. (Somat) has completed the geotechnical investigation for the development of the Great Lakes Water Authority (GLWA) Design Services for Combined Sewer Outfall (CSO) Improvements Project at the Oakwood CSO Facility in the City of Detroit, Wayne County, Michigan.

Somat was retained by CDM Smith to perform a pre-design geotechnical investigation for the referenced project within the project limits. The geotechnical investigation was performed in general accordance with Somat Proposal No. P210314B dated January 12, 2022. The results of the investigation will be used to support the design of the project and development of construction specifications.

1.2 PROJECT INFORMATION

The overall project includes design services required to implement a series of improvements at the Oakwood CSO Retention Treatment Basin (RTB) and storm/sanitary pumping station located at 12220 Pleasant Street, Detroit, Michigan. The site improvements include constructing a new access service drive that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin and expanding the existing bioswale on the west side of the basin to improve drainage conditions.

The following sections of this report provide a description of our field investigation, the results of the field and laboratory tests, the logs of auger probes, our interpretation of subsoil and groundwater conditions, recommendations related to the proposed construction.

2.0 SUBSURFACE INVESTIGATION

2.1 FIELD EXPLORATION

The field exploration program consisted of performing a total of six (6) hand auger probes, designated OAK-01 through OAK-06. Borings OAK-01, 02, and 03 were performed along the existing gravel access road and extended to a depth ranging between 5 and 5.5 feet below existing grades. In-situ Dynamic Cone Penetrometer (DCP) tests were performed at each of these probes to assess the strength of the subgrade soils and support the pavement section design of the access road.

Hand auger probes OAK-04, 05, and 06 were performed along the existing bioswale that is located on the west side of the basin. These probes extended to depths ranging between 4 and 6 feet below existing grades. In-situ infiltration tests were performed near each of these probes at depths ranging between 4 and 6 feet below existing grades.

Soil boring coordinates and the ground surface elevations (included in the soil boring logs) were provided by the Project Surveyor. A schematic of the approximate soil boring locations and the corresponding infiltration test locations can be found in Appendix A. The Logs of Test Borings are included in Appendix B.

2.1.1 Drilling Operations

The drilling operations were performed on December 1 and December 2, 2022. The hand auger probes were performed using a 3-inch hand auger bucket. Upon completion, all boreholes were backfilled with soil cuttings and the site was restored to the best of our ability.

2.1.2 Geotechnical Sampling

Bulk soil samples were collected from each hand auger probe at every apparent stratum change. The samples were sealed in plastic zip lock bags in the field to protect the soil and maintain the soil's natural moisture content. All samples were identified with unique information on hand auger

number, sample number, and sample depth. The samples were transported to Somat's laboratory in Romulus, Michigan.

All soil samples for the geotechnical investigation were transported to Somat's laboratory for further analysis and testing and will be retained in our laboratory for a period of 90 days after the date of the final report, after which they will be discarded unless we are notified otherwise.

2.1.3 In-Situ Dynamic Cone Penetrometer (DCP) Tests

A dual-mass Dynamic Cone Penetrometer (DCP) test was performed in general accordance with ASTM D6951 at probes OAK-01, 02, and 03. The test was performed starting at the surface material, and extended to depths of about 4 feet below existing grade, approximately. The DCP test is utilized to estimate the California Bearing Ratio (CBR) values from 0.1 to 100. A CBR value is an index commonly used in pavement design, indicative of base and subgrade support characteristics for granular soils. The test procedure involves dropping a 17.6-pound hammer from a distance of 22.6 inches onto an anvil/coupler assembly that drives the graduated drive rod with a disposable cone or tip. The cone has a 60° angle with a maximum diameter of 0.79 inches. The rate of cone penetration per blow is measured at selected penetration or hammer drop intervals. The analysis was performed based on relationships developed by USACE to estimate the California Bearing Ratio (CBR) value from the results of the DCP test. The correlated CBR values ranged between 10 and 100 (an outlier CBR of 4.8 was eliminated). The DCP test results and correlated CBR values are presented in Appendix C.

2.1.4 Groundwater Level Observation Procedures

Whenever possible, groundwater level observations were made during the augering operations and are shown on the individual Logs of Auger Probes. During augering, the depth at which free water was observed, where soil cuttings became saturated or where saturated samples were collected, was indicated as the groundwater level during drilling. In granular, pervious soils, the indicated water levels are considered relatively reliable when hand auger probes are used. However, in cohesive soils, groundwater observations are not necessarily indicative of the static water table

due to the low permeability rates of the soils, and due to the sealing off of natural paths of groundwater flow during augering operations.

It should be noted that seasonal variations and recent precipitation may influence the level of the groundwater table significantly. Groundwater observation wells are generally used if precise groundwater table information is needed, however, the installation of groundwater monitoring wells was not included in the scope of the investigation. Therefore, the discussion and recommendations provided within the report are based on our knowledge of the soil and groundwater conditions in this area, which should provide for a reasonable approximation of the groundwater level.

2.1.5 In-Situ Falling Head Permeability Test

The falling head in-situ permeability testing was performed in accordance to the Stormwater Management Design Manual of the City of Detroit Water and Sewerage Department (2018 which is adapted from the Philadelphia Water Stormwater Management Guidance Manual (Philadelphia Water, 2015). The permeability tests consisted of the following steps:

1. Advance a borehole to the required depth of the proposed infiltration interface depth of 4 to 6 feet using a 6-inch hand auger bucket. The augured hole diameter is at least two inches larger than the outer diameter of the inner casing. The inner casing will consist of a PVC pipe with minimum inner diameter of four inches.
2. Push the inner casing within the augured hole to the infiltration interface and firmly set into the bottom of the borehole. Measure the depth from the top of casing to the bottom of the hole to the nearest 0.1 feet.
3. Place two inches of fine gravel or coarse sand in the bottom of the borehole to prevent scour during filling of the casing. Place gravel or sand uniformly to obtain an even depth within the hole. Re-measure the depth from the top of casing to the gravel or sand surface to the nearest 0.1 feet.
4. Presoak test holes immediately prior to testing to simulate saturated conditions. Fill casing with water at a very low rate so as not to disturb the bottom sediments. Place water to a depth of at least six inches above the bottom and readjust every 30 minutes for one hour. The drop in the water level during the last 30 minutes of the presoaking period to be applied to the following standard to determine the time interval between readings:
 - a. If water level drop is two inches or more, use ten-minute measurement intervals.

- b. If water level drop is less than two inches, use 30-minute measurement intervals.
5. After the presoaking, the water level is measured using an approved method per the ASTM standard, where the water level remains at least 12 inches above the bottom of the bottom of the hole. All water added was recorded as a volume along with the time of addition.
6. Measurements of water level were made from the top of casing and continued at the interval determined until a minimum of eight readings are completed or until a stabilized rate of drop was obtained, whichever occurred first. A stabilized rate of drop means a difference of about 0.25 inch or less of a drop between the highest and lowest readings for four consecutive readings.
7. Calculate the infiltration rate as described in ASTM D6391.

The results of the permeability tests and the graphic presentation of the calculated mean hydraulic conductivity, K_1 , versus the elapsed time at each test location are discussed in Section 3.3 and presented in Appendix D.

2.2 GEOTECHNICAL LABORATORY TESTING

All soil samples were classified in accordance with the Unified Soil Classification System (USCS). Cohesive soil samples were subjected to laboratory tests consisting of moisture content determinations, hand penetrometer tests, grain size analysis, and Atterberg Limits tests. Loss-on-ignition (LOI) tests were performed on any samples that appear to contain significant organic content.

The results of the soil classifications and the laboratory tests are included on the respective Logs of Auger Probes in Appendix B and/or tabulated or presented graphically in Appendix E. All laboratory tests were performed in accordance with their applicable ASTM procedures. A general description of each test method is presented in Appendix E, immediately following the result sheets.

2.3 LIMITATIONS

The scope of our services was strictly geotechnical and did not include environmental investigation. Our scope of services did not include investigation for the presence or absence of wetlands or hazardous or toxic materials in the soil, surface water, groundwater, or air, on, below or around this site.

Somat has made no observations or recommendations with regard to the presence or absence of mold or other biological contaminants (such as spores, fungi, bacteria, viruses, and the byproducts of such organisms), now or in the future, on this site or within or on any structures to be constructed on this site. Any consideration with regard to the presence of mold, or the possibility of mold growth in or on the structure to be constructed on this site are not within our scope of services on this project.

Some soils have been identified on the Logs of Test Borings as “fill” or “possible fill” if a soil deposit is suspected to have been placed by human activity, versus having been deposited by natural means. These designations were based on our professional engineering judgment considering factors such as our visual classification, the presence of foreign materials (i.e., bricks, concrete, plastic, etc.), and/or site topography, among many other possibilities. As such, the “fill” or “possible fill” descriptions should be considered as secondary information to the standardized soil classification. Due to the large variation of types of fill, methods of fill placement, potential changes of historical use of the site, and soil sample size, it is difficult to discern whether the subject soil sample is native to this site, or fill material based on visual classification alone. As such, the designation of “fill” may not be reliable and hence should be considered as informational only. Conversely, where a soil is not designated as “fill” on the boring logs, it does not necessarily mean it is not a fill soil, only that there were no apparent observations indicating a fill material. Therefore, we cannot guarantee that our description of “fill” soils is accurate, or that we have identified all types of fill material encountered with our sampling on the site.

3.0 SUBSURFACE CONDITIONS

3.1 SOIL CONDITIONS

Soil conditions encountered at the boring locations have been evaluated and presented in the form of logs of auger probes. The logs of auger probes include approximate soil stratification with detailed soil descriptions and selected physical properties for each stratum encountered in the auger probes. In addition to the observed subsoil stratigraphy, the auger logs present information relating to

sample data, groundwater level conditions observed in the probing, personnel involved, and other pertinent data. For information, and to aid in understanding the data as presented on the auger logs, General Notes defining nomenclature used in soil descriptions are presented immediately following the Logs of Test Borings. It should be noted that the Logs of Test Borings included with this report have been prepared on the basis of laboratory classifications and testing as well as field logs of the soils encountered.

A generalized description of the soils and pavement encountered in the six (6) auger probes beginning at the existing ground surface and proceeding downward, is provided below:

Stratum 1: Surface Material:

- **Topsoil:** Clayey topsoil was encountered at the surface of OAK-04, OAK-05, and OAK-06 and had a thickness of 6 inches.
- **Roadway Materials:** Fill soils consisting of a mixture of crushed aggregate and silty sand were encountered at the surface of OAK-01, OAK-02, and OAK-03. These fill soils extended to depths ranging between 0.8 and 1.5 feet below existing grades and had fines content ranging between 11 and 25% (silt and clay).

Stratum 2: Fill Soils:

- **Granular Fill:** Silty sand and clayey sand fill soils with varying amounts of silt and gravel were encountered below the topsoil in OAK-04 and 05, and below the roadway gravel in OAK-01, 02, 03. The fill soils extended to depths ranging between 2 and 5.5 feet below existing grades. The granular fill extended to the termination depths of auger probes OAK-01 and OAK-03. The fines content ranged between 11 and 43%. Few organics were encountered in the granular fill soils in OAK-03 at a depth of about 3 feet below existing grades. Based on the Loss-On-Ignition (LOI) test the organic content was 7.2%.

Stratum 3: Native Cohesive Soils

- Native brown and gray lean clay or sandy lean clay soils were encountered generally below the fill soils in OAK-02 and OAK-05, and below the topsoil in OAK-06 and extended to the explored depths of the auger probes at 4 to 6 feet below existing grades. The consistency of the clay was stiff to very stiff. The moisture content of the native clays ranged between 15 and 45%. Based on the Atterberg limits test result on the clay sample obtained from a depth of 5 feet at probe OAK-01 the liquid limit was 38% and the plasticity Index (PI) was 18%. Graphical presentation of the Atterberg Limits results plotted on the Casagrande chart shows that the clay is classified as lean clay (CL). The chart is presented in Appendix E.

The Logs of Auger Probes are presented in Appendix B and the Hand Auger Probe Location Diagram is presented in Appendix A. It is emphasized that the stratification lines shown on the Logs of Test Borings are approximate indications of change from one soil type to another at the locations of the boreholes. The actual transition from one stratum to the next may be gradual and may vary within the area represented by the test boring.

3.2 GROUNDWATER LEVEL OBSERVATIONS

Groundwater was not encountered during drilling or upon completion of any of the hand auger probes.

A lack of groundwater in some of the auger holes, does not necessarily mean there is no groundwater in this area, due to the sealing off of natural flow paths during the drilling process. Oftentimes, a change in color from brown to gray in cohesive soils is a good indication of the long-term groundwater level (indicating oxidation). Based on the change from brown to gray in the cohesive soils of OAK-04 and OAK-06, the long-term groundwater table is estimated to be situated at about 3.3 to 4 feet below existing grades (EL. XXX).

Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected.

It should be noted that the elevation of the long-term groundwater table is likely to vary throughout the year depending on the amount of precipitation, runoff, evaporation, and percolation in the area, as well as on the water level in any surface water bodies in the vicinity affecting the groundwater flow pattern.

3.3 IN-SITU FALLING HEAD PERMEABILITY TEST RESULTS

The in-situ falling head permeability testing was performed in accordance to the Stormwater Management Design Manual of the City of Detroit Water and Sewerage Department (2018 which

is adapted from the Philadelphia Water Stormwater Management Guidance Manual (Philadelphia Water, 2015).

Per the request of CDM Smith, the infiltration tests were performed at about 4 to 6 feet below existing grades in the native soils. The mean hydraulic conductivity, K_1 , is defined as the average rate of water movement through a saturated soil mass, as tested for the in-situ permeability testing using the falling water level method. The mean hydraulic conductivity was calculated based on the equation adopted from ASTM D6391-11.

The equation is as follows:

$$K_1 = R_T G_1 \frac{\ln\left(\frac{Z_1}{Z_2}\right)}{(t_2 - t_1)}$$

Where:

K_1 is the mean hydraulic conductivity in inch/hour and in cm/sec

G_1 is the test setup parameter

R_T is the temperature coefficient

t_1 and t_2 are the time interval in seconds

Z_1 and Z_2 are the head measurements in cm, measured from the bottom of the borehole to the water level.

The results of the hydraulic conductivity, in equivalent inches per hour, at each testing location were then compared to soil textures of the U.S. Department of Agriculture (USDA) textural triangle presented in Table 3.3-1 to identify the general soil texture and the corresponding hydrologic soil grouping. The following table is an excerpt of the USDA Classification Table:

Table 3.3-1 - Summary Table of Hydraulic Soil properties Classified by Soil Texture

Texture class	Minimum Infiltration Rate (Hydraulic Conductivity) (Inch/hour)	Hydrologic Soil Grouping
Sand	8.27	A
Loamy Sand	2.41	A
Sandy Loam	1.02	A
Loam	0.52	B
Silt Loam	0.27	B
Sandy Clay Loam	0.17	C
Clay Loam	0.09	D
Silty Clay Loam	0.06	D
Sandy Clay	0.05	D
Silty Clay	0.04	D
Clay	0.02	D

The following Table 3.3-2 summarizes the mean hydraulic conductivity measured at each borehole and interpretation for the corresponding soil texture and hydrologic group based on the referenced USDA soil group. The results of the in-situ falling head tests and the graphic presentation of the mean hydraulic conductivity (in cm/sec) versus the elapsed time (in seconds) at each test location are presented in Appendix D.

Table 3.3-2 Summary Table of the In-Situ Falling Head Permeability Tests Results

Hand Auger Probe ID	Mean Hydraulic Conductivity, K_1 (cm/sec)	Mean Hydraulic Conductivity, K_1 (inch/hour)	General Soil Texture and the Corresponding Hydrologic Soil Grouping*	
			Texture Class	Hydrologic Soil Grouping
OAK-04	7.062E-06	0.01	Clay	D
OAK-05	1.736E-05	0.025	Clay	D
OAK-06	5.181E-06	0.007	Clay	D

*Based on soil textures of the U.S. Department of Agriculture (USDA) Textural Triangle

Based on the in-situ falling head permeability tests performed at a depth of 4 to 6 feet below existing grades, the mean hydraulic conductivity of these soils ranged between 0.007 and 0.025 inch/hour (1.7E-05 – 5.2E-06 cm/sec).

4.0 GEOTECHNICAL RECOMMENDATIONS

4.1 PROPOSED ACCESS SERVICE DRIVE

The project includes the construction of a new paved access service drive around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. The current design calls for a total length of about 1,000 lineal feet and a width of 16 feet. The proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

4.1.1 Existing Subgrade Conditions

Based on the hand auger probes, the existing access road consists of 10 to 18 inches of a mixture of gravel and silty sand (road gravel) over granular fill soils. Based on the laboratory grain size analysis performed on the surface gravel layer, the fines content ranged between 11 and 25% which is considered excessive. Also, the gradation does not conform with the gradation of MDOT 21AA because the percent finer by weight was exceeded for the ½ inch, #8, and #200 sieves. As such, we do NOT recommend re-using the existing road gravel material as a base course below the new pavement because the excessive fines may reduce the ability of the material to effectively allow drainage below the pavement and may pose a risk of detrimental frost action.

The existing granular fill soils below the gravel layer consisted of poorly graded sand with silt and silty sand which extended to a depth of 4.5 to 5.5 feet below existing grades. Native stiff clay was encountered at a depth of 4.5 feet in boring OAK-02 and extended to the explored depth of 5 feet.

A pocket of organics was encountered at a depth of about 3 feet at the location of probe OAK-03. Loss-On-Ignition (LOI) test performed on that soil sample showed an organic content of 7.2% which is considered excessive. We recommend undercutting the soils at that location and removing the organics to avoid settlement under the new pavement due to the decomposition of the organic material.

Typically, we do not recommend constructing new pavement on undocumented fill soils. However, except as noted in OAK-03, the existing fill soils do not appear to contain excessive organic material or debris, and given the density of the sand fill, these existing subgrade soils are considered suitable for the direct support of new pavement. However, it must be noted that the risk of premature pavement cracking, faulting or uneven settlement should be considered when placing a pavement on a non-engineered fill material. If the risk of this type of distress is not tolerable, then it may be necessary to remove some of the existing non-engineered fill and replace it with engineered fill. We recommend a geotechnical engineer or qualified technician confirm the suitability of the subgrade soils in the field at the time of construction.

4.1.2 Subgrade Preparation and Groundwater Control Recommendations

Once a rough subgrade has been achieved, the exposed pavement subgrade along the entire sections of access service drive to be constructed should be visually checked for the presence of debris, organic matter, and other unsuitable material.

If unsuitable or highly organic subgrade soils (organic contents greater than 4%) are encountered during construction, the material should be assessed by the on-site geotechnical engineer to determine the depth and extent of the material and whether it should be fully undercut.

All of the pavement subgrade areas should be thoroughly proof rolled before placement of the new base course and pavement. The purpose of the proof rolling is to locate overly loose or soft areas as well as to uniformly compact the subgrade surface. In granular soils, proof rolling should be performed with a heavy (minimum 30 ton) self-propelled vibratory roller. Loose or soft areas revealed during compaction or during the proof rolling should either be suitably compacted and aerated if necessary. Any areas that exhibit excessive pumping or yielding should be stabilized, scarified, and re-compacted, if weather conditions permit, or by the removal of the yielding soils and their replacement with engineered fill.

The pavement subgrade will need to be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D-1557 (Modified Proctor). It may be necessary in some areas to undercut unsuitable soils and replace them with a stabilization layer of engineered fill.

Based on the change from brown to gray in the cohesive soils encountered at OAK-04 and OAK-06, the long-term groundwater table is estimated to be situated at a depth of about 3.3 to 4 feet below existing grades (EL. XXX). Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected. We do not expect the excavations required to construct the access service drive would extend below the estimated long-term groundwater. As such, we believe the groundwater should be adequately controlled using standard sump pits and pumping methods.

4.1.3 Drainage Considerations

The effects of frost heave are anticipated to be more significant in areas where water is not allowed to drain freely either due to subsoil conditions, site grades, or other factors. We recommend including a new drainage system within the new base course to drain water away from the pavement. The pavement and subgrade will need to be positively graded towards these drainage features or away from the center of the roadway to allow for gravity flow of groundwater. As we understand, the storm runoff from the site will be collected and conveyed to the storm junction chamber upstream of the Oakwood CSO.

For all new pavements, final pavement elevations should be designed to provide positive surface drainage. The minimum surface slope of 2 percent is recommended. The pavement surface should be smooth, free of roller marks or depressions, and should not contain any irregularities which would pond or impede water flow

4.1.4 Pavement Design Recommendations

4.1.4.1 Subgrade Design Values

We anticipate the subgrade soils for the proposed pavement construction will consist of existing fill soils. The recommended subgrade resilient modulus (M_R) and vertical subgrade reaction (K_v) provided below assumes the soil conditions encountered in the auger probes are representative of the soil conditions within the proposed pavement construction areas. This also assumes the recommended earthwork operations will have been incorporated into the project specifications and that the subgrade soils will have been compacted. If during construction, the subgrade is found to vary from the expected soil conditions, we should be contacted so we may re-evaluate our soil design parameters.

For Portland cement concrete pavement design, based on our experience with similar soil conditions and the results of the in-situ DCP tests, we recommend the following coefficients of subgrade reaction (K_v), subgrade resilient moduli (M_R), and CBR's be used as representation for the conditions of the soils at the new base course and subgrade levels compacted to project specifications.

Table 4.1.4.1 Recommended Pavement Subgrade Design Parameters

Soil Type	Coefficient of Vertical Subgrade Reaction, (K_v)	Subgrade Resilient Moduli (M_R)	CBR
Existing Granular Fill subgrade compacted in place	175 pci	15,000 psi	10 (lowest CBR value shown in the in-situ DCP tests)
Existing Native Clay Soils	85 pci	6,000 psi	4
New Engineered Sand Fill (MDOT Class II)	235 pci	22,500 psi	15
New Engineered Aggregate Base (MDOT 21AA)	340 pci	37,500 psi	25

Other factors should also be considered in the final pavement design, in addition to the subgrade modulus values. These factors may include, but are not limited to, adequate subgrade preparation, adequate placement of engineered fill and pavement layers, and surface and subsurface drainage.

4.1.4.2 Pavement Section Design Recommendations

As we understand, the proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

We performed pavement analysis utilizing the AASHTO 1993 Guide for Design of Pavement Structures and the associated design charts and nomographs. The following list summarizes our input parameters and assumptions based on AASHTO guidelines and our observations:

Pavement Design Life	20 years (7 days per week)
Loading	HS-20 (8,000 lb/ front axle and two 32,000 lb/ rear axles (Given)
Load Equivalent Factor (LEF)	2.985 (calculated based on HS-20 loading using AASHTO LEF tables for terminal serviceability of 2.5)
Maximum Average Daily Traffic (ADT)	200 vehicles per day with HS-20 loading criteria (Back calculated)
Maximum Design ESAL's:	4,200,000 ESAL (Back calculated)
Percent Trucks:	100 %
Reliability:	90 % (Arterial road)
Standard Deviation:	0.35 (Rigid pavement)
Drainage Coefficient:	1.0
Initial Serviceability:	4.5 (Rigid pavement)
Terminal Serviceability:	2.5 (Major collectors)
Growth Rate	3%
Load Transfer Coefficient	2.7 (Dowel and mesh)
Concrete Elastic Modulus	6,000,000 psi (Assumed)
Effective Modulus of Subgrade Reaction of new base course (MDOT 21AA)	340 pci (CBR =25)
Mean Concrete Modulus of Rapture	650 psi

Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted existing granular fill soils prepared as noted in this report; should be adequate to support the proposed traffic loading for the service drive.

4.2 PROPOSED BIOSWALE

As we understand, there are areas around the CSO basin that are poorly drained. On the basin's west side, there is an existing shallow drainage swale with dimensions of approximately 360 feet by 30 feet. The current plan calls for expanding and improving this swale to increase its volume to accept the flow that is discharged from the west side of the basin roof during wet weather.

A total of three (3) hand auger probes were performed along the existing bioswale. These probes were OAK-04, 05, and 06 and each extended to a depth of 6 feet, 4 feet, and 5 feet, respectively.

Based on the findings of the hand auger probes, the soils consisted of 6 inches of topsoil over a granular fill layer over the native clay. The granular fill layer encountered in probes OAK-04 and OAK-05 consisted of silty sand and clayey sand soils, and had a thickness of 4 and 18 inches, respectively. Laboratory grain size analysis performed in accordance with ASTM D6913 indicated that the fines content of this granular layer was 43%, which is considered excessive.

In-situ falling head permeability tests were performed in the native clay soils at the termination depths near the probes. The infiltration tests were performed in offset boreholes within 2 feet from the locations of the sampling probes per the guidelines of the City of Detroit stormwater manual. Based on the in-situ infiltration tests the mean hydraulic conductivity (K1) of the native clay ranged between 0.007 and 0.025 inch per hour, which is considered almost impermeable.

Based on the findings of the infiltration tests, we recommend undercutting the existing granular fill soils and some of the native clays and replacing with drainable engineered fill in conformance

to the Green Infrastructure Solution (GIS) design. The geometry of the new expanded swale (length, width, depth, and thickness of the granular soils) shall be designed by the GIS Engineer based on the maximum anticipated surface water runoff at the site.

The GIS design engineer should also consider the level of the anticipated long-term groundwater at the site during the design of the bioswale and the associated drainage systems. Based on the findings at the time of the geotechnical investigation (December 2022), the long-term groundwater table is estimated to be situated at a depth of about 3.3 to 4 feet below existing grades (EL. XXX).

5.0 GENERAL QUALIFICATIONS

All construction activities should be monitored under the direction of a qualified Geotechnical Engineer to verify conditions as interpreted in this report. This report and the attached Logs of Auger Probes are instruments of service, which have been prepared in accordance with generally accepted soil and foundation engineering practices. We make no other warranties either expressed or implied as to the professional advice included in this report.

The contents of this report have been selected in order to aid in the evaluation of expected subsoil properties to assist the Engineer in the design of this project. In the event that any changes are made in the geotechnical aspects of this project, however slight, the conclusions and recommendations contained in this report shall not be considered valid unless the changes are reviewed, and the conclusions of this report are modified in writing by our office.

Since the information obtained from auger probes is specific to the exact test locations, soil and water information could be different from those occurring at other locations of the site. This report does not reflect variations which may occur between the test holes. The nature and extent of these variations may not become evident until the time of construction. If significant variations then become evident, it may be necessary for us to re-evaluate the recommendations provided in this report.

This report and the associated soil logs should be made available to bidders prior to submitting their proposals and to the successful Contractor and subcontractors for their information only, and to supply them with facts relative to the subsurface investigation, laboratory tests, etc.

The discussions and recommendations submitted in this report are based on the soil information contained in the Logs of Auger Probes and test results appended to this report. We expect that the logs of auger probes, test results, and the soil profiles included in this report along with our discussions and conclusions will assist you in designing the proposed pavement. Please refer to Appendix F for important information about this geotechnical investigation report. If you have any questions regarding this report, please contact us.

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2488 (Modified)

DRILLING & SAMPLING SYMBOLS:

SS:	Split Spoon – 1 3/8" I.D., 2" O.D. (standard)	BS:	Bulk Sample	RC:	Rock Core with diamond bit, NX size, (unless otherwise noted)
S:	Split Spoon – non-standard size, as noted	HSA:	Hollow Stem Auger	RB:	Rock Bit/Roller Bit
ST:	Thin-Walled Tube – 3" O.D., (unless otherwise noted)	DP:	Direct Push	WR:	Wash Rotary
LS:	Liner Sample	PS:	Piston Sample	NR:	No Recovery
PA:	Power Auger	PT:	Pitcher Sample	VS:	Vane Shear Test
HA:	Hand Auger	WS:	Wash Sample	ER:	Hammer Energy Ratio
AU:	Auger Sample				

Standard Penetration Test Resistance, N-Value: Sum of 2nd and 3rd 6-inch increments, in blows per foot of a 140-pound hammer falling 30 inches and driving an 18-inch to 30-inch long, 2-inch OD split spoon.

WATER LEVEL MEASUREMENT:

Water levels indicated on the boring logs are the levels measured in the borings at the times indicated. In pervious soils, the indicated levels may reflect the location of a groundwater table. In low permeability soils (clays and silts), the accurate determination of groundwater levels may not be possible with only short-term observations. Groundwater levels at times and locations other than when and where individual borings were performed could vary.

DESCRIPTIVE SOIL CLASSIFICATION:

Soil classification is based on the Unified Soil Classification (USC) System and ASTM Standards D-2487 and D-2488. Coarse-grained soils have more than 50% of their dry weight retained on a #200 sieve; they are described as: gravel or sand. Fine-grained soils have less than 50% of their dry weight retained on a #200 sieve; they are generally described as: clays, if they are plastic, and silts, if they are slightly plastic or non-plastic. Major constituents may be added as modifiers and minor constituents may be added according to the relative proportions based on grain size. In addition to gradation, coarse-grained soils are defined on the basis of their apparent in-place density and fine-grained soils on the basis of their apparent in-place density (silty soils) or consistency (clayey soils).

CONSISTENCIES OF COHESIVE SOILS:

The pocket penetrometer, pocket torvane, and in-situ vane shear tests are converted into an estimated unconfined compressive strength, in pounds per square feet (psf), for presentation on the logs. The unconfined compressive strength is estimated to be about two time the shear strength.

DESCRIPTORS OF MINOR CONSTITUENTS

Primary Constituent	Fine-Grained (Silt & Clay)	Coarse-Grained (Sand & Gravel)	
Descriptor of Other Constituents	Relative Portion of Coarse Grained Soils as a % of Dry Weight	Relative Portion of Fine Grained Soils as a % of Dry Weight	Relative Portion of Coarse Grained Soils as a % of Dry Weight
Trace	<5%	<5%	<5%
Few	≥5% - <15%	N/A	≥5% - <15%
With	≥15% - <30%	≥5% - 12%	≥15%
Modifier	≥30%	>12%	N/A

FINE-GRAINED SOILS

Unconfined Compressive Strength Q_u , psf	Consistency	N-Value	Apparent Density
< 500	Very Soft	0 – 4	Very Loose
500 - <1,000	Soft	5 – 9	Loose
1,000 - <2,000	Medium	10 – 29	Medium Dense
2,000 - <4,000	Stiff	30 – 49	Dense
4,000 - <8,000	Very Stiff	50 – 80	Very Dense
≥ 8,000	Hard	>80	Extremely Dense

COARSE-GRAINED SOILS

DEFINITIONS OF PAVEMENT CONDITION

Condition	Description
Good	ACC Very slight or no raveling, surface shows some traffic wear. Longitudinal cracks and transverse cracks (open ¼ inch). No patching or very few patches in excellent condition.
	PCC Moderate scaling in several locations. A few isolated surface spalls. Shallow reinforcement causing cracks. Several corner cracks, tight or well sealed. Open (¼ inch wide) longitudinal or transverse joints.
Fair	ACC Severe surface raveling. Multiple longitudinal and transverse cracking with slight raveling. Longitudinal cracking in wheel path. Block cracking (over 50% of surface). Patching in fair condition. Slight rutting or distortions (½ inch deep or less).
	PCC Severe polishing, scaling, map cracking, or spalling over 50% of the area. Joints and cracks show moderate to severe spalling. Pumping and faulting of joints (½ inch with fair ride). Several slabs have multiple transverse or meander cracks with moderate spalling.
Poor	ACC Alligator cracking (over 25% of surface). Severe distortions (over 2 inches deep) Extensive patching in poor condition. Potholes.
	PCC Extensive slab cracking, severely spalled and patched. Joints failed. Patching in very poor condition. Severe and extensive settlement or frost heaves.

DEFINITIONS OF STRUCTURAL AND DEPOSITIONAL FEATURES

Term	Definition
Parting	≤ 1/16 inch (1.6 mm) thick
Seam	> 1/16 inch (1.6 mm) → ½ inch (12.7 mm) thick
Layer	> ½ inch (12.7 mm) to ≤ 12 inches (305 mm) thick
Pocket	Small, erratic deposits of limited lateral extent
Lens	Lenticular deposit
Lensed	Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay
Varved	Alternating partings or seams (1 mm – 12 mm) of silt and/or clay and sometimes fine sand
Stratified	Alternating layers of varying material or color with layers ≥ 6 mm thick
Laminated	Alternating layers of varying material or color with layers < 6 mm thick
Fissured	Contains shears or separations along planes of weakness
Slickensided	Shear planes appear polished or glossy, sometimes striated
Blocky	Cohesive soil that can be broken down into small angular lumps which resist further breakdown
Homogeneous	Same color and appearance throughout
Occasional	One or less per foot (305 mm) of thickness
Frequent	More than one per foot (305 mm) of thickness
Interbedded	Applied to strata of soil lying between or alternating with other strata of a different nature

GRAIN SIZE TERMINOLOGY

Major Component of Sample	Size Range
Boulders	≥ 12" (300 mm)
Cobbles	< 12" - 3" (300 mm – 75 mm)
Gravel - Coarse	< 3" - ¾" (75 mm – 19 mm)
Gravel - Fine	< ¾" - #4 (19 mm – 4.75 mm)
Sand - Coarse	< #4 - #10 (4.75 mm – 2 mm)
Sand - Medium	< #10 - #40 (2 mm - 0.425 mm)
Sand - Fine	< #40 - #200 (0.425 mm - 0.074 mm)
Silt	< 0.074 mm - 0.005 mm
Clay	< 0.005 mm

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2487

Criteria for Assigning Group Symbols and Group Names Using Laboratory Tests ^A				Soil Classification	
				Group Symbol	Group Name <i>B</i>
COARSE-GRAINED More than 50 % retained on No. 200 sieve	Gravels (More than 50 % of coarse fraction retained on No. 4 sieve)	Clean Gravels	$Cu \geq 4$ and $1 \leq Cc \leq 3^D$	GW	Well-graded gravel ^E
		(Less than 5% fines ^C)	$Cu < 4$ and/or $[Cc < 1$ or $Cc > 3]^D$	GP	Poorly graded gravel ^E
		Gravels with Fines	Fines classify as ML or MH	GM	Silty gravel ^{E,F,G}
		(More than 12 % fines ^C)	Fines classify as CL or CH	GC	Clayey gravel ^{E,F,G}
	Sands (50 % or more of coarse fraction passes No. 4 sieve)	Clean Sands	$Cu \geq 6$ and $1 \leq Cc \leq 3^D$	SW	Well-graded sand ^I
		(Less than 5 % fines ^H)	$Cu < 6$ and/or $[Cc < 1$ or $Cc > 3]^D$	SP	Poorly graded sand ^I
		Sands with Fines	Fines classify as ML or MH	SM	Silty sand ^{F,G,I}
		(More than 12 % fines ^H)	Fines classify as CL or CH	SC	Clayey sand ^{F,G,I}
FINE-GRAINED SOILS 50 % or more passes the No. 200 sieve	Silts and Clays Liquid limit less than 50	inorganic	PI > 7 and plots on or above "A" line ^J	CL	Lean clay ^{K,L,M}
			PI < 4 or plots below "A" line ^J	ML	Silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OL	Organic clay ^{K,L,M,N}
					Organic silt ^{K,L,M,O}
	Silts and Clays Liquid limit more than 50	inorganic	PI plots on or above "A" line	CH	Fat clay ^{K,L,M}
			PI plots below "A" line	MH	Elastic silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OH	Organic clay ^{K,L,M,P}
					Organic silt ^{K,L,M,Q}
HIGHLY ORGANIC SOILS	Primarily organic matter, dark in color, and organic odor			Pt	Peat
^A Based on the material passing the 3-in. (75-mm) sieve. ^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name. ^C Gravels with 5 to 12 % fines require dual symbols: GW-GM well-graded gravel with silt GW-GC well-graded gravel with clay GP-GM poorly graded gravel with silt GP-GC poorly graded gravel with clay ^D $Cu = D_{60}/D_{10}$ $Cc = (D_{30})^2 / (D_{10} \times D_{60})$ ^E If soil contains ≥ 15 % sand, add "with sand" to group name. ^F If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM. ^G If fines are organic, add "with organic fines" to group name. ^H Sands with 5 to 12 % fines require dual symbols: SW-SM well-graded sand with silt SW-SC well-graded sand with clay SP-SM poorly graded sand with silt SP-SC poorly graded sand with clay ^I If soil contains ≥ 15 % gravel, add "with gravel" to group name. ^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay. ^K If soil contains 15 to <30 % plus No. 200, add "with sand" or "with gravel," whichever is predominant. ^L If soil contains ≥ 30 % plus No. 200, predominantly sand, add "sandy" to group name. ^M If soil contains ≥ 30 % plus No. 200, predominantly gravel, add "gravelly" to group name. ^N $PI \geq 4$ and plots on or above "A" line. ^O $PI < 4$ or plots below "A" line. ^P PI plots on or above "A" line. ^Q PI plots below "A" line.					

Order of Classification: 1) Consistency or Apparent Density, 2) Type of Soil, 3) Minor Soil Type(s), 4) Inclusions, 5) Layered Soils, 6) Color, 7) Water Content, 8) USCS Symbol, 9) Geological Name

(1) Number of hammer blows between test readings	(5) (3) divided by (1)
(2) Cumulative cone penetration after each set of hammer blows.	(6) Enter 1 for 17.6 lb. hammer, 2 for 10.1 lb. hammer.
(3) Incremental penetration between blow sets	(7) (5) x (6)
(4) Cumulative total of blows	(8) From CBR versus DCP Correlation.

The graph plots Penetration (mm) on the y-axis against Blows on the x-axis. The y-axis scale is inverted, with 0 at the top and 1600 at the bottom. The x-axis scale ranges from 0 to 250 blows. The data points are connected by a smooth curve, showing that penetration increases as the number of blows increases.

IN-SITU FALLING HEAD PERMEABILITY TEST RESULTS

PROJECT: Great Lakes Water Authority (GLWA)
Design Services for Combined Sewer Outfall (CSO)
Improvements Projects GWLA Oakwood CSO Facility
Detroit, Michigan

PROJECT NO: 2022136A

PRESOAK START DATE/TIME/DURATION: 12/1/2022 11:33

TEST START DATE/TIME 12/1/2022 12:03

TEST END DATE/TIME 12/1/2022 13:02

FIELD ENGINEER/ANALYST: A. Patil

BOREHOLE DRILL DATE: 12/1/2022

BOREHOLE LOCATION: Grass

TOP OF BOREHOLE/GROUND ELEV.: _____

LATITUDE: _____

LONGITUDE: _____

COORDINATES/ELEVATION NOTES: Project Surveyor

In-situ falling head permeability test and calculations performed per guidelines adapted from the Philadelphia Water Stormwater Management Guidance Manual (Philadelphia Water, 2015) and ASTM D-6391 Method A

EQUIPMENT

PRESSURE TRANSDUCER In-Situ Level TROLL 700

DATA LOGGER SOFTWARE Win-Situ 5

DATA INPUT

CASING DIAMETER, D1 6.0 in.

CASING DIAMETER (inside casing), d 6.0 in.

DISTANCE BOTTOM OF CASING TO BOTTOM OF STRATUM, b1 10.0 ft.

TEST DEPTH (below existing grade) 6.0 ft.

APPROX. TEST ELEVATION -6.0 ft.

EQUATIONS

Mean hydraulic conductivity (K1):
(Equations obtained from D6391-11)

$$K1 = Rt \cdot G1 \cdot \ln(H1/H2) / (t_2 - t_1) \quad (\text{cm/sec}) \quad \text{eq. 1}$$

$$G1 = (\pi d^2 / 11 D1) [1 + a(D1/4b1)] \quad (\text{cm}) \quad \text{eq. 2}$$

Rt = temperature coefficient (varies)

a = material at the test depth = 1

G1 = test setup parameter 4.407 (calculated based on data input)

- 1.) Use inner diameter of casing for "D1" and "d" because no standpipe was used
- 2.) Rt calculated as $2.2902(0.9842^T)^{0.1702}$ and T is temperature in °C
- 3.) "a" in eq. 2 is "-1" for permeable base; or "1" for impermeable base below test stratum
- 4.) b1 is distance from bottom of casing to bottom of stratum
- 5.) H1 and H2 are the the level surface elevations at times t1 and t2

MEAN HYDRAULIC CONDUCTIVITY (K1)

K1 7.062E-06 cm/sec (0.010 inch/hour)

SOIL TYPE AT TEST DEPTH

DESCRIPTION DEPTH (ft.)

LEAN CLAY, few sand, trace gravel 6.0

NOTES: Groundwater encountered during drilling: none
Groundwater reported upon completion of drilling: none

GRAIN SIZE GLWA OAKWOOD AND LEIB CSO FACILITIES.GPJ SOMAT.GDT 12/18/22

Description of Frequently Used Laboratory Testing Procedures

Visual Engineering Classification

Visual classification was performed on all samples (though other means of refining the classification may also be used). The General Notes provided immediately following the Logs of Test Borings include a brief discussion of the general method used to visually classify the soil, which is based on the visual-manual procedure (ASTM D2488). The visual classification is used to assign an appropriate Unified Soil Classification System (USCS) group symbol. The USCS symbol is shown in parentheses following the textural description of the various strata on the boring logs.

Where more laboratory testing is performed (requiring both grain size and Atterberg limit tests), the classification may also be refined further based on USCS ASTM D2487.

Moisture Content (ASTM D2216)

Moisture content determination tests were performed in accordance with ASTM D2216. Samples were sealed in the field to retain the natural moisture content of the soil specimen. Samples were then dried at a constant temperature (approximately 110° C) overnight in an oven. After drying, the samples were weighed to determine the dry weight of the sample (and the loss in weight representing the water contained in the original sample). The moisture content of the specimen is expressed as a percent and is the weight of the water compared to the dry weight of the specimen.

Hand Penetrometer

A hand/pocket penetrometer was used to estimate the unconfined compressive strength of cohesive (clay) samples. In the hand penetrometer test, the shear strength of a cohesive soil sample is estimated by measuring the resistance of the sample to the penetration of a small, calibrated spring-loaded cylinder. The maximum capacity of the penetrometer is 4.5 tons per square foot. The shear strength is doubled and reported on the soil boring logs as an estimate of the unconfined compressive strength.

Grain Size Analyses (ASTM D6913, D7928, and/or D422-2017)

Grain size analyses were performed in accordance with ASTM D6913, D7928, and/or D422-2017 on selected soil samples to evaluate the gradation of the soil represented by the sample. The distribution of particle sizes larger than 75 micrometers (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 75 micrometers is determined by a sedimentation process using a hydrometer.

Atterberg Limits Tests (ASTM D4318)

Determination of the Liquid Limit, Plastic Limit, and Plasticity Index of cohesive soils (known as Atterberg Limits) were performed in accordance with ASTM D4318. Fine-grained soils are tested to determine the Liquid Limit (LL) and Plastic Limits (PL), which are moisture contents that define boundaries between material consistency states. The LL and PL values define the transitional boundaries between non-plastic, plastic, and viscous fluid states. The plasticity index (PI) defines the complete range in water content for the plastic state.

Description of Frequently Used Laboratory Testing Procedures (continued)

Organic Content (Loss-On-Ignition) Tests (ASTM D7348)

The organic content of a soil is determined through a Loss-On-Ignition test performed in accordance with ASTM D2974 on soil samples suspected to contain significant organics. After the sample has been oven-dried, the soil sample is super-heated in a 440°C muffle furnace as a means to burn off all present organic matter. The weight of the remaining ash is used to calculate the percentage of organic matter as compared to the dry weight of the sample.

GEO-PROFESSIONAL BUSINESS ASSOCIATION (GBA) MESSAGE

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, you can benefit from a lowered exposure to problems associated with subsurface conditions at project sites and development of them that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed herein, contact your GBA-member geotechnical engineer. Active engagement in GBA exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Understand the Geotechnical-Engineering Services Provided for this Report

Geotechnical-engineering services typically include the planning, collection, interpretation, and analysis of exploratory data from widely spaced borings and/or test pits. Field data are combined with results from laboratory tests of soil and rock samples obtained from field exploration (if applicable), observations made during site reconnaissance, and historical information to form one or more models of the expected subsurface conditions beneath the site. Local geology and alterations of the site surface and subsurface by previous and proposed construction are also important considerations. Geotechnical engineers apply their engineering training, experience, and judgment to adapt the requirements of the prospective project to the subsurface model(s). Estimates are made of the subsurface conditions that will likely be exposed during construction as well as the expected performance of foundations and other structures being planned and/or affected by construction activities.

The culmination of these geotechnical-engineering services is typically a geotechnical-engineering report providing the data obtained, a discussion of the subsurface model(s), the engineering and geologic engineering assessments and analyses made, and the recommendations developed to satisfy the given requirements of the project. These reports may be titled investigations, explorations, studies, assessments, or evaluations. Regardless of the title used, the geotechnical-engineering report is an engineering interpretation of the subsurface conditions within the context of the project and does not represent a close examination, systematic inquiry, or thorough investigation of all site and subsurface conditions.

Geotechnical-Engineering Services are Performed for Specific Purposes, Persons, and Projects, and At Specific Times

Geotechnical engineers structure their services to meet the specific needs, goals, and risk management preferences of their clients. A geotechnical-engineering study conducted for a given civil engineer

will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client.

Likewise, geotechnical-engineering services are performed for a specific project and purpose. For example, it is unlikely that a geotechnical-engineering study for a refrigerated warehouse will be the same as one prepared for a parking garage; and a few borings drilled during a preliminary study to evaluate site feasibility will not be adequate to develop geotechnical design recommendations for the project.

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project or purpose;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, the reliability of a geotechnical-engineering report can be affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying the recommendations in it. A minor amount of additional testing or analysis after the passage of time – if any is required at all – could prevent major problems.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read the report in its entirety. Do not rely on an executive summary. Do not read selective elements only. *Read and refer to the report in full.*

You Need to Inform Your Geotechnical Engineer About Change

Your geotechnical engineer considered unique, project-specific factors when developing the scope of study behind this report and developing the confirmation-dependent recommendations the report conveys. Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the elevation, configuration, location, orientation, function or weight of the proposed structure and the desired performance criteria;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project or site changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept*

responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

Most of the “Findings” Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site’s subsurface using various sampling and testing procedures. *Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing is performed.* The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgement to form opinions about subsurface conditions throughout the site. Actual site-wide subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team through project completion to obtain informed guidance quickly, whenever needed.

This Report’s Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgement and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* exposed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals’ misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a continuing member of the design team, to:

- confer with other design-team members;
- help develop specifications;
- review pertinent elements of other design professionals’ plans and specifications; and
- be available whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction-phase observations.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note*

conspicuously that you’ve included the material for information purposes only. To avoid misunderstanding, you may also want to note that “informational purposes” means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. This happens in part because soil and rock on project sites are typically heterogeneous and not manufactured materials with well-defined engineering properties like steel and concrete. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled “limitations,” many of these provisions indicate where geotechnical engineers’ responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a “phase-one” or “phase-two” environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually provide environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures.* If you have not obtained your own environmental information about the project site, ask your geotechnical consultant for a recommendation on how to find environmental risk-management guidance.

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, the engineer’s services were not designed, conducted, or intended to prevent migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, *proper implementation of the geotechnical engineer’s recommendations will not of itself be sufficient to prevent moisture infiltration.* Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. *Geotechnical engineers are not building-envelope or mold specialists.*
