WRD	Water Resources Division
WRRF	Water Resource Recovery Facility
WSE	water surface elevation
WWMP	Wastewater Master Plan

Executive Summary

The Great Lakes Water Authority (GLWA) hired CDM Smith, the design and consulting engineer, to develop a Project Plan to apply for a Clean Water State Revolving Fund (CWSRF) loan through the Michigan Department of Environment, Great Lakes and Energy (EGLE). This Project Plan was prepared for in accordance with the CWSRF Project Planning Document Preparation Guidance (January 2023).

The Intent of the CWSRF project is to Implement a series of improvements at the Oakwood Combined Sewer Overflow (CSO) Retention Treatment Basin (RTB) and storm/sanitary pumping station, and the Leib CSO Screening and Disinfection Facility (SDF). The goal of the CWSRF project is to implement improvements that will significantly upgrade the process mechanical and instrumentation and control (I&C) systems and site improvements at both facilities, as well as heating, ventilation, and air conditioning (HVAC), architectural, structural, electrical, and site civil improvements. Based on the analysis summarized in this project plan, the selected improvements include:

- 1) Comprehensive upgrades to the Oakwood and Leib disinfection systems, including replacement of chemical storage and feed systems and sampling systems intended to improve process control and reliability, reduce operations and maintenance costs, standardize with other CSO facility improvements, and accommodate future flows and disinfection requirements.

- 2) New and improved sewage sampling and monitoring throughout each facility to continuously monitor total residual chlorine demand and decay and optimize the chemical usage.

Modification of the existing Oakwood CSO RTB storm pumps, and modifications to pump controls for the storm and sanitary pumping systems, to maximize service life and reliability of equipment while reducing operating cost and seal water usage.

- 3) Replacement of the existing COPA screens at Leib with Romag screens so that operations and maintenance are standardized around identical equipment instead of multiple technologies.

Modifications to the flushing and drainage systems throughout each facility to facilitate future automated cleaning and reduce frequency and difficulty of manual cleaning between CSO events.

- 4) General civil work, intended to facilitate site access for staff and waste disposal and chemical shipment vehicles, enhance site security, repair damaged pavement, and improve site drainage.

- 5) Architectural improvements, intended to facilitate separation of unclassified and hazardous classified areas (Leib), repair and recoat modified facilities, and accommodate improvements to HVAC equipment access.

- 6) Major modifications to the Leib CSO SDF screen channels to accommodate new and rehabilitated screens including improved maintenance access.

1.0 Background

The Great Lakes Water Authority (GLWA) operates and maintains nine combined sewer overflow (CSO) facilities. The primary function of the CSO facilities is to screen, settle, skim, and disinfect combined sewer/storm water during rain events before discharge to the receiving water body or return captured water to the Wastewater Resource Recovery Facility (WRRF) for further treatment. These CSO facilities play a vital role in keeping combined sewer water out of residents of the City of Detroit's basements and protecting public health and the environment. All facilities must meet discharge requirements contained in GLWA's National Pollutant Discharge Elimination System (NPDES) permit (see **Appendix B**). Detailed facility descriptions are provided in the following sections.

There are two types of CSO facilities: Retention Treatment Basins (RTBs) and Screening and Disinfection Facilities (SDFs). Both facilities provide screening and disinfection. The RTB provides dedicated settling within a retention basin. The SDFs provide contact time for disinfection within effluent conduits prior to discharge to the river. The effluent conduits are up to 1 mile long.

Table 1.1 presents key existing design criteria and general information for the Oakwood and Leib CSO SDF.

Table 1.1 – Oakwood and Leib Existing Facility Overview

	Leib	Oakwood
Facility Abbreviation	LEIB	OKW
Facility Type	SDF	RTB
Year of Startup	2002	2012
Hydraulic Capacity (cfs)	2,000	1,660
River Level Basis for Hydraulic Capacity (Detroit Datum)	Not influenced by river elevation	N/A
Treatment Capacity ^a (cfs)	1,550	1,660
Storage Volume (MG)	N/A	9
Screen Type (size of slot or opening)	Racked Vertical and Horizontal Bar Screens (4-mm)	Perforated Plate (6-mm)
Disinfectant Type	Liquid Sodium Hypochlorite (NaOCl)	
Receiving Water Body	Detroit River	Rouge River

^a Treatment capacity refers to the design capacity of the screening and disinfection systems.

Notes:

cfs = cubic feet per second

MG = million gallon(s)

mm = millimeter(s)

N/A = not applicable

NaOCl = sodium hypochlorite

In 2021, GLWA along with Jacobs Engineering, performed an assessment (CS-299 CSO Facilities Assessment, Volume 2 – Multi-Disciplinary Facilities Assessment, April 9, 2021) of various CSO facilities. This assessment identified needs for projects to address issues identified at Oakwood and Leib pertaining to equipment reliability, process optimization, and accommodating new flows from the Northwest Interceptor (NWI) and Meldrum interceptors which are being routed to Oakwood and Leib

respectively in response to recommendations from the wastewater master plan (WWMP) (Great Lakes Water Authority Wastewater Master Plan, 2020).

1.1 Study and Service Areas

The Oakwood CSO RTB and Leib CSO SDF study areas are in the City of Detroit, located in Wayne County, servicing approximately 2.9 million residents 1.16 million households. The service areas are shown in **Figure 1.1**. The Oakwood CSO RTB is located 12220 Pleasant Street, Detroit, MI 48217 on the lower portion of the Rouge River immediately south of I-75. The Leib CSO SDF is located at 2198 Mt Elliot Street, Detroit, MI 48217.

Figure 1.1 – Oakwood CSO RTB and Leib CSO SDF locations

Figure Error! No text of specified style in document.2 - Oakwood CSO RTB Aerial Map (1220 Pleasant Street)

Figure 1.3 – Leib CSO SDF Aerial Map (2198 Mt Elliot Street)

1.2 Population

Population projections were made for the 2020 wastewater master plan (*Great Lakes Water Authority Wastewater Master Plan, 2020*). Population projections were based on the Southeast Michigan Council of Governments (SEMCOG) forecast for 2045 supplemented by GLWA Member surveys and extrapolation to the year 2060.

SEMCOG prepares annual analyses of population and households by local unit of government within its 7-county planning region. The 2045 forecast was completed in June 2018. Population forecasting, and the associated economic and demographic projections that drive population growth, is an essential component of master planning. Population change directly impacts sanitary wastewater flows (including domestic, commercial, industrial, and institutional flows) and the increase in the size of the service area (infiltration/inflow).

Based on the Member survey and SEMCOG projections from the wastewater master plan, the GLWA regional service area population is forecast to grow up to 9 percent by the year 2060:

- 2.75 million residents in 2018
- 2.77 million residents in 2025
- 2.90 million residents in 2045
- 3.06 million residents in 2060

1.3 Existing Environmental Evaluation

1.3.1 Cultural and Historic Resources

The Oakwood and Leib CSO facilities are adjacent to the Rouge River and the Detroit River, respectively.

A search of the Michigan Historic Site Online did not identify any state registered historical sites near the proposed project sites.

State agencies including the State Historic Preservation Center (SHPO), EGLE Water Resources Division (WRD), Michigan Department of Natural Resources (MDNR) offices of endangered species and wildlife and fish will be contacted for review.

The proposed project has the possibility to have impacts on tribally important cultural or religious sites of the following American Indian tribes in Wayne County: Bay Mills, Grand Traverse Band of Ottawa and Chippewa Indians, Gun Lake Tribe, Hannahville, Keweenaw Bay Indian Community, Lac Vieux Desert Band of Lake Superior Chippewa Indians, Little River Band of Ottawa Indians, Little Traverse Bay Bands of Odawa Indians, Nottawaseppi Huron Band of the Potawatomi, Pokagon Band of the Potawatomi Indians, Saginaw Chippewa Indian Tribe of Michigan, and Sault Tribe of Chippewa Indians. These tribes will be contacted to review the proposed sites.

1.3.2 Air Quality

The most recent EGLE Air Quality Report (2022) is reviewed to assess the air quality in the study area. Since EGLE began monitoring in the early 1970s, criteria pollutant levels have decreased, indicating that the air is much cleaner today than when the federal Clean Air Act began. The entire state of Michigan is in attainment for carbon monoxide, lead, nitrogen dioxide, and particulate matter. Portions of the state are in nonattainment, for sulfur dioxide and ozone, but the levels of these pollutants are continuing to decrease.

1.3.3 Wetlands

Wetland maps for the Oakwood and Leib CSO facilities were generated at the U.S. Fish and Wildlife Service (USFWS) National Wetlands Inventory website. The maps are included in **Appendix C**.

River Rouge is directly adjacent to the Oakwood CSO facility. The Detroit River is also adjacent to the Leib CSO SDF. These riverine systems are not anticipated to be impacted by this project.

1.3.4 Great Lakes, Shorelands, Coastal Zones, and Coastal Management Areas

The proposed project is not expected to impact the Great Lakes, Shorelands, Coastal Zones, or Coastal Management Areas.

1.3.5 Natural or Wild and Scenic Rivers

Natural or Wild and Scenic Rivers, particularly Rogue River and Detroit River, are not expected to be impacted upon the construction of the proposed project.

1.3.6 Major Surface Waters

The main surface water body within the project areas are the Rogue River and the Detroit River. These rivers are intensively developed, with extensive urban, commercial, and industrial complexes. They are not expected to be negatively impacted upon construction of the proposed project. Improvements at the Oakwood CSO RTB and Leib CSO SDF will improve the quality of the water being discharged into both of the rivers.

1.3.7 Topography

Appendix C includes the existing topography from the USGS quadrangle maps. The city of Detroit is relatively flat. The study area is part of the vast central lowlands of North America, consisting of plains and low hills.

1.3.8 Floodplains

The project work area lies outside of the 100-Year Floodplain. FEMA issued Flood Plain Maps are shown in **Appendix C**. There are no special flood hazards near the Oakwood and Leib CSO facilities. Consequently, the proposed project is not expected to impact floodplains.

1.3.9 Geology

There are no geological structures or formations in the vicinity of the proposed project study areas.

1.3.10 Soil Types

At the Oakwood CSO facility, the soils consist of clayey topsoil, fill soils (mixture of crush aggregate and silty sand), silty sand and clayey sand fill soils, and native brown and gray lean clay or sandy lean clay soils.

At the Leib CSO SDF, the soils consist of clayey topsoil, granular fill soils consisting of sand with silt, and native sandy lean clay.

1.3.11 Agricultural Resources

There is no agricultural land within the Oakwood CSO RTB or Leib CSO SDF service areas. Consequently, the proposed project is not expected to impact agricultural resources.

1.3.12 Fauna and Flora

A USFWS Section 7 review will be completed for this project. According to the USFWS website, there are 3 federally listed endangered species including the Indiana Bat (*Myotis sodalis*), the Northern Riffleshell (*Epioblasma torulosa rangiana*), and White Catpaw (*Epioblasma obliquata perobliqua*).

Because the proposed work is limited to the existing facilities, it was determined that no impacts to federally listed endangered or threatened species are anticipated.

1.4 Existing System

1.4.1 Leib CSO SDF Existing System

The Leib CSO Facility is an SDF with a treatment capacity of 1,550 cfs. It was constructed in 2002. The facility has a nearly 1-mile-long effluent conduit used for disinfection contact time before discharge into the Detroit River. The facility consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground outfall vault near the river.

1.4.1.1 Disinfection

The sodium hypochlorite disinfection system consists of two fiber-reinforced plastic (FRP) tanks, six low-rate diaphragm pumps, two high-rate centrifugal pumps, four disinfectant rapid mix zones, and 18 induction mixers. There are two channels with four ROMAG screens and two channels with Copa screens discharging into screened effluent channels. From there screened effluent flows to four disinfectant rapid mix zones. There are four induction mixers per disinfectant rapid mix zone consisting of one pair of mixers upstream and one pair of mixers downstream of a concrete baffle wall that directs all flow down and past the mixers. There are also two induction mixers in the influent channel upstream of screening referred to as prechlorination mixers. Four of the low-rate sodium hypochlorite pumps are each paired to a disinfectant rapid mix zone. Flow is metered from each pump and then flow is split in a manifold to the four induction mixers in each disinfectant rapid mix zone. The manifold includes a solenoid valve, manual valve, and a sight flow indicator to each induction mixer. Flow splitting between induction mixers is primarily dependent on equal back pressure valve settings to the induction mixers. The other two low-rate sodium hypochlorite pumps are each paired to one of the influent channel mixers. The two

high-rate pumps discharge to a four-way manifold with flow metering on each branch. These tie into the discharge from the four low-rate pumps upstream of the manifold to each disinfectant rapid mix zone. There are also valved connections allowing the high-rate pumps to be used for the influent channel induction mixers.

The design which was intended to provide redundancy and flexibility is atypically complex and results in the manifolds including valves and sight flow indicators to be inaccessible due to their height on the wall.

Table 1.2 provides an overview of the existing disinfection system at Leib CSO SDF.

Table 1.2 – Leib Disinfection Details

Parameter	Value
Treatment Capacity (cfs)	1,550
Design Feed Strength (% hypochlorite)	5.0
Max. Dosage at Design Flow (mg/L Cl ₂)	38
Disinfection Contact Time (min)	10
Storage Tanks	
Number	2
Volume of Each Tank (gal)	10,450
Material	FRP
Pumps	
Number	8 Total; 6 low-rate, 2 high-rate
Capacity (gpm)	Low-rate: 7.6, High-rate: 112
Type	Low-rate: Diaphragm, High-rate: Centrifugal
Mixers	
Number / Type	18 / Chemical induction mixers
Model Number/ hp / Manufacturer	SWC15FX / 15 / Water Champ

1.4.1.2 Screening

The Leib CSO SDF has two types of screens: 1) raked horizontal bar screen (manufactured by COPA) and 2) raked vertical bar screens (manufactured by Romag). Constructed in 2002, the facility was intended to be a full-scale pilot facility for this type of fine screen. There are four screening channels in the facility, with a total of eight COPA screens and a total of four Romag screens.

During dry weather, raw sewage is routed through the facility and to the Toward Treatment Sewer. During wet weather events, the flow increases, and the flow enters the screening channels as the wet weather flow exceeds the capacity of the Toward Treatment Sewer.

Screenings are conveyed to the Toward Treatment Sewer and then the Detroit River Interceptor (DRI) for eventual removal at the WRRF by the portion of influent conveyed to screenings collection channel. The COPA screens recently received a complete overhaul in 2019. The existing Romag screens were also rebuilt in 2019; however, the control panels and power packs were not upgraded.

Table 1.3 provides an overview of the existing screening system at Leib CSO SDF.

Table 1.3 – Leib Screening Details

Parameter	Value	
Treatment Capacity (cfs)	1,550	
No. of Screens	4 (2 in each of 2 channels)	8 (4 in each of 2 channels)
Manufacturer	Romag	COPA
Screen Type	Raked Vertical Bar Screen	Raked Horizontal Bar Screen
Opening Size	4-mm spacing	4-mm spacing
Depth or Length	29 ft 6 in	17 ft 0 in
Width	4 ft 0 in	4 ft 0 in
Screen Cleaning	Mechanical Comb	Mechanical Comb
Screening Removal	Conveyed to Toward Treatment Sewer and then to WRRF	

1.4.1.3 Flushing and Dewatering

The Leib CSO SDF does not have a dedicated dewatering or flushing system for the screening and disinfection area. The facility drains by gravity and, due to the limited use, solids accumulation has not been a major issue at this facility, except for the screening channels. However, in the future with connection of Meldrum sewer, the number of events will increase.

The outfall conduit has dewatering pumps to dewater the lower portion of the effluent conduit. These pumps are located near the Outfall Sample Building. The dewatered flow is pumped to the DRI.

Table 1.4 provides an overview of the existing flushing and dewatering system at Leib CSO SDF.

Table 1.4 – Leib Flushing and Dewatering Details

Parameter	Value
Headworks Dewatering and Flushing System	Headworks (basin) area is dewatered by gravity to the Toward Treatment sewer or disinfection (effluent) conduit. Manual flushing of screens and channels after each wet weather event.
Effluent Conduit Dimensions	16-ft-dia. effluent sewer to Junction Chamber, two 11-ft-dia. pipes to dewatering gate, two 10 ft × 10.5 ft box conduits to Detroit River
Effluent Conduit Dewatering and Flushing System	Two 1,500 gpm dewatering pumps located near Effluent Sample Building are used to dewater lower end of effluent conduit. Flow is pumped to the DRI. There is no flushing system in the effluent conduit.

1.4.1.4 Odor Control

There is no odor control system at the Leib facility. Building space for a carbon adsorber system, space in the electrical room for the fan motor, and a duct penetration to the screening facility below grade were provided, if odor control is needed in the future. However, odor complaints have not been received for this facility since it has been in operation. Therefore, an odor control system is not needed.

There is a need to isolate the hazardous classified screen area from the unclassified main building to eliminate the existing path for hazardous gases to migrate to the unclassified area. The duct will be sealed at each end and filled with sand to provide this required isolation between these spaces.

1.4.1.5 HVAC

The Leib CSO SDF consists of a Headworks area in the basement, chemical room, utility support (electrical, emergency generator and mechanical rooms), control room, sample room, supply fan room and other miscellaneous rooms. The facility also includes an underground influent channel. **Table 1.5** provides summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, electric water heater, and emergency eyewash shower. Emergency shower/eye washes are addressed, if safety issues were discovered, in **Section 1.4.1.10**.

Table 1.5 – Leib HVAC Equipment Details

Location	Unit No.	Description	Capacity (Per Unit)
Headworks (Screening Chamber)	SF-1	Supply Fan	59,000 CFM
Chemical Room	HV-2	Air Handling Unit	2,700 CFM 300 MBH
	EG-2	Exhaust Fan	3,010 CFM
Electrical Room	HV-1	Air Handling Unit	2,700 CFM 300 MBH
	EF-3	Exhaust Fan	4,650 CFM

1.4.1.6 Electrical

The Leib facility's electrical system consists of one DTE Energy utility feed from a 480 V, 3-phase outdoor transformer (secondary metering) and one diesel generator feed from a 350 kW, 480 V, 3-phase stationary generator. The utility feed is connected to a 600 A motor control center (MCC-B) with a 600 A sub-feed connection to a 600 A automatic transfer switch (ATS). The ATS then feeds a distribution panel with two 600 A breakers, which feeds two MCCs (MCC-A and MCC-C). The MCCs feed the various pumps, valves, motors, transformers, panels, etc. at the facility. **Table 1.6** provides a summary of the major electrical equipment for this facility.

Table 1.6 – Leib Electrical Details

Location	Major Electrical Equipment	Description
Generator Room	Generator (Diesel)	350 kw, 480/277 V, 3-Phase
Electrical Room	MCC-A	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-B	600 A, 480/277 V, 3-Phase
Electrical Room	MCC-C	600 A, 480/277 V, 3-Phase

1.4.1.7 Instrumentation and Controls

Control System: The original control system was installed in 2002 under PC-732. In 2004 the system was upgraded and interfaced into GLWA's overall supervisory control and data acquisition (SCADA) Ovation control system. This upgrade provided the ability to remotely monitor the operations of the facility and the local collection system at the system control center (SCC).

The existing control system contains an Allen Bradley-based programmable logic controller (PLC) system consisting of an Allen-Bradley redundant PLC-5 with local I/O controls that are installed in the facility's local control system panel. The operator workstation software has a Rockwell RSView operating platform and is located in the control room. The existing hardwired local back-up control panel and other miscellaneous subsystems that are incorporated into the overall control system are outdated and need replacement. The control system network and switches are obsolete and do not meet GLWA SCADA Governance standards on redundant networks and switches, and that all CSO facilities use Ovation workstations with new high-performance graphics. The current system is equipped with a back-up radio system to communicate critical monitoring points back to GLWA System Control on wide area network failure. Improvements to the control system are currently on-going as part of another project focused on upgrade to GLWA standard system controls for the existing process and instrumentation equipment.

Flow and Level Sensors: **Table 1.7** summarizes the level sensors and flow meters at the Leib CSO SDF for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 1.7 – Leib Flow and Level Sensors Details

Area	Quantity	Instrument Type
CSO Flow Meters		
Influent Sewer (Larger Sewer)	1	Transit-Time (AccuSonic)
Influent Sewer (Smaller Sewer)	1	Transit-Time (AccuSonic)
Towards Treatment Sewer	1	Transit-Time (AccuSonic)
Outfall	1	Transit-Time (AccuSonic)

Area	Quantity	Instrument Type
CSO Facility Level Sensors		
Influent (Sewer and channel)	2	Ultrasonic
Mixing Chamber	1	Ultrasonic
Effluent (Outfall, Towards Treatment Sewer)	2	Ultrasonic
DRI Discharge Regulator Chamber	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed Pumps	8	Magnetic

1.4.1.8 Site Civil

The Leib CSO facility was built in 2002. The site includes a 6-ft high security fence along the perimeter of the site. A sliding cantilever entrance gate is provided at the Mt. Elliott entrance. The parking lot consists of 8-in thick reinforced pavement with 8-in. crushed limestone base. There is a 5-ft wide, 4-in. thick sidewalk along the building entrances and 10-in. aggregate site pavement along the perimeter of the facility. Site utilities include potable water, natural gas, electrical, telephone services, stormwater, and sanitary sewer connections.

1.4.1.9 Architectural

The Leib CSO SDF consists of chemical room, utility support (electrical, emergency generator and mechanical), control room, odor control room, screen room, sampler room and other miscellaneous rooms. The facility also includes an underground influent channel, screen area, mixing chamber and effluent channel.

1.4.1.10 Safety

Safety related items include fall protection, exit signage, hatch access, handrails, and other miscellaneous safety-related features.

1.4.2 Oakwood CSO RTB Existing System

The Oakwood CSO Facility is an RTB with 9 million gallons (MG) of storage and a treatment capacity of 1,660 cfs. It was constructed in 2012. There are three buildings. The main building contains the Storm Pump Station (PS), Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, make-up air unit (MAU) room and hydraulic room. The basin odor control room contains the odor control systems for the East and West Basins.

1.4.2.1 Disinfection

The sodium hypochlorite disinfection system consists of two FRP tanks, 10 gear pumps, and multiport injection on the discharge of the eight-stormwater vertical mixed flow pumps. The storm pump pumps stormwater into the screen facility. Three of the sodium hypochlorite pumps are low-rate and seven are high-rate. Sodium Hypochlorite Pumps 1 through 8 inject on the discharge pipe of Storm Pumps 1 through 8, respectively. Sodium Hypochlorite Pump 9 is a high-rate pump serving as the backup to high-rate pumps 3 through 8. Sodium Hypochlorite Pump 10 is a low-rate pump serving as the backup to low-

rate pumps 1 and 2. Each pump has a variable frequency drive (VFD) to adjust chemical feed flow based on storm pumping rate. Flow is metered from each pump. The disinfection system is summarized in **Table 1.8**.

Table 1.8 – Oakwood Disinfection Details

Parameter	Value
Treatment Capacity (cfs)	1,660
Design Feed Strength (% hypochlorite)	7.5
Max. Dosage at Design Flow (mg/L Cl ₂)	12
Disinfection Contact Time (min)	6 min w/ 1 CSO basin, 12 min w/ 2 CSO basins in service
Storage Tanks	
Number	2
Volume of Each Tank (gal)	11,500
Type	FRP
Pumps	
Number	10 Total; 3 low-rate, 7 high-rate
Capacity (gpm)	Low-rate: 0-26, High-rate: 151
Type	Gear
Mixers	
Number / Type	Hypo added to pump discharge pipe.
Model Number/ hp / Manufacturer	Not Applicable (Hypo added to pump discharge pipe where mixed as conveyed to Screen Facility)

1.4.2.2 Screening

The Oakwood CSO Facility has six perforated plate screens that were placed into service in 2012 (see **Table 1.8**). Raw wastewater is pumped to the screens from the Oakwood Storm Pump Station. Screened flow enters either one or both of the CSO basins via the Screen Outlet Chamber.

Screened material is removed from the screens using a rotating brush and high-pressure spray and discharged into a screw conveyor. The conveyor transports the screenings to a dumpster for eventual disposal in a landfill. A washer/compactor/grinder is installed at the end of the conveyor, prior to discharge to the dumpster.

1.4.2.3 Storm Pump Station

The storm water pump station consists of eight vertical mixed flow pumps. Design criteria is presented in **Table 1.9**. The pump station is divided into two equal sized wet wells. Each wet well contains one smaller pump and three larger pumps. The storm pumps are equipped with an external flushing water system for bearing cooling and lubrication. The seal water system consists of secondary water piping with a dedicated seal water booster pump for each storm pump. As the wet wells fill, the storm pumps start based on the wet well levels and control system logic. The station was designed for operation using a constant-level control strategy. Features of this control strategy include narrow wet well operating range, pump speed ramping up and down, and pumps turning on/off to match a set level. This requires pumps with VFDs and a high degree of turn-down capability for the pumps. The station is typically manually controlled as that control strategy has not been well aligned with the influent flow characteristics during wet weather events.

Table 1.9 – Oakwood Storm Pump Station Details

Storm Pump No.	Design Capacity, MGD	Total Head, ft	Drive Type
1 and 2	97	48	VFD
3, 4, 7, and 8	178	48	Constant Speed
5 and 6	178	48	VFD

1.4.2.4 Sanitary Pump Station

The Sanitary Pump Station of the Oakwood CSO Facility consists of two separate wet wells (east and west) and an enclosed sanitary pump station room located at ground level. Each wet well includes two submersible sanitary sewage pumps for a total of four pumps. Even numbered pumps (SN2 and SN4) are located in the east wet well, while odd numbered pumps (SN1 and SN3) are located in the west wet well.

1.4.2.5 Odor Control

There are three odor control systems at the Oakwood facility. One system, located in the Odor Control Building next to the sanitary pump station, treats air from the east and west storm wet wells, the sanitary wet wells, and the sanitary pump station room. The second and third systems, both located in the Basin Odor Control Building, treat air from the East and West Retention Basins. Each of the retention basin odor control systems also serves the headworks, as it is connected to both CSO basins.

The system serving the pump stations consists of a grease filter/mist eliminator, an odor control fan, and a single bed vertical activated carbon vessel. The system also includes a bypass ventilation fan, which allows foul air to be removed from the pump stations and bypass the carbon column. Carbon is replaced through the top access hatch on each vessel.

The systems serving the retention basins operate in parallel. Each system consists of an odor control fan and an activated carbon vessel (there are no grease filter/mist eliminators). Each system also has a bypass ventilation fan.

These odor control systems operate under air permit requirements (Permit to Install No. 91-06). The emission limit for the Pump Station system is 0.0043 pounds per hour (pph) of hydrogen sulfide. At a design air flow of 30,000 cfm, this equates to approximately 0.028 parts per million volume (ppmv) concentration of hydrogen sulfide. The emission limit for the CSO basin systems is 0.0031 pph. At a design air flow rate of 22,000 cubic feet per minute (each), this equates to approximately 0.028 ppmv concentration of hydrogen sulfide. The carbon is tested for remaining bed life on a quarterly basis as required by the permit. Carbon was replaced in all three carbon vessels in Spring 2018, which was the first time it was replaced since it was put into service in 2012.

In 2021, GLWA reported no odor complaints have been received for at least the past three years.

1.4.2.6 Flushing and Dewatering

Dewatering System: The Oakwood screening facility and CSO basins (East and West) are largely dewatered by gravity through drain lines that discharge to the NWI. The CSO drain system has sufficient capacity to allow both CSO basin drain valves to be opened simultaneously; however, there is a flow control valve and magnetic flow meter provided on the drain line to the NWI to control the flow to the

NWI to prevent overflows in the collection system between the CSO Basin and the WRRF. Also, there is a Surge Chamber on the gravity drain lines that will direct flow back to the head of the plant if the basin dewatering flow rate exceeds the available capacity in the line to the NWI. Refer to **Table 1.10** for overview of the dewatering system.

Due to system hydraulics, the water in the lowest levels of the basins that cannot be discharged to the NWI by gravity is instead routed back to the Oakwood Pump Station, where flow is pumped by the sanitary pumps to the NWI.

Flushing System: A flushing gate system (see **Table 1.10**) is used for cleaning solids from the floor of the basin following dewatering. There are 20 total flushing gates—eight in each of the two CSO basins, and two in each of the two basin influent channels. The flushing gates in each basin are arranged in two groups of four. The flushing gates operate in a latch-unlatch manner and are controlled by a common hydraulic power pack. The flushing reservoirs are filled as the basins fill during a wet weather event. When the basin and screening facilities dewater, flushing water remains behind the flushing gates. Flushing is initiated by sequentially unlatching two basin flushing gates (one in each basin) at a time until all are open. Then, if the last of the four reservoirs was full prior to its gate opening, the second set of flushing gates will sequentially open. Once basin flushing is completed, one gate is opened in each influent channel. The flushing sequence only allows one gate in each channel to be open at a time.

Table 1.10 – Oakwood Flushing and Dewatering Details

Parameter	Value
Total Basin Volume (MG)	9
Headworks and Basin Dewatering and Flushing System	▪ Basins are dewatered by gravity by opening the Drain Valve to the NWI ▪ There are 20 flushing gates: 8 in each basin and 2 in each basin distribution channel ▪ Flushed solids are routed to the Oakwood Pump Station for pumping to the NWI

1.4.2.7 HVAC and Plumbing

The Oakwood CSO facility consists of three buildings. The main building contains the Storm Pump Station, Sanitary Pump Station, chemical room, control room, utility support (electrical and mechanical rooms), odor control room, sample room, shipping and receiving and miscellaneous other rooms. The Headworks Building contains the headworks, headworks control room, MAU room and hydraulic room. The Basin Odor Control Room contains the odor control systems for the East and West Basins.

Table 1.11 provides a summary of the major HVAC equipment for this facility.

Plumbing services for the facility consist of city water service, natural gas service, sanitary system, gas-fired water heater, emergency shower/eye wash, emergency eye wash, sump pumps, pressure booster pumping system, and compressed air system.

Table 1.11 – Oakwood HVAC Details

Location	Unit No.	Description	Capacity (Per Unit)
Main Pump Station	SF-1 to 2	Supply Fan	5,000 CFM
Headworks (Screen Facility)	MAU-3	MAU	35,800 CFM 3,000 MBH
CSO Basin	EF-20 to 22	3 × Exhaust Fan (East Basin)	52,800 CFM
	EF-23 to 26	3 × Exhaust Fan (West Basin)	52,800 CFM
	SF-5 to 7, SF-10	4 x Supply Fan (East Basin)	52,800 CFM
	SF-5, SF-8 to 10	4 x Supply Fan (West Basin)	52,800 CFM
Chemical Room	AC-2	Air Conditioning Unit	315 CFM 1.25 ton
	MAU-4	MAU	5,000 CFM 400 MBH
	EF-18	Exhaust Fan	2,500 CFM
Electrical Room	AHU-1	AHU	25,000 CFM, Cooling Capacity (125 tons), Heating Capacity (353 MBH)
	EF-35	Exhaust Fan	13,880 CFM
	EUH-8	Electric Unit Heater	1,700 CFM 15 KW
Mechanical Room	AHU-1A	AHU	2,700 CFM
Make-up Air Room	MAU-3	MAU	35,800 CFM
Odor Control Room	EF-28, EF-29	Exhaust Fan	3,000 CFM
	EF-33, EF-34	Exhaust Fan	22,000 CFM
	EUH-6 to 7	Electric Unit Heater	1,700 CFM 15 KW

1.4.2.8 Electrical

The Oakwood facility's electrical system consists of double ended 4.8 kV, 3,000 A switchgear with dual (redundant) utility feeds, metering of the 4.8 kV feeds and an adjacent DTE substation with two 15 MVA outdoor transformers. The switchgear has a tiebreaker and automatic source transfer controls. Circuit breakers in the switchgear then feed eight storm pumps and two 2,500 kVA outdoor pad mount transformers. The 2,500 kVA transformers then feed a double ended 480 V, 3,200 A switchboard with a key interlocked tie-breaker. Circuit breakers in the switchboard then feed four MCCs and four 125 hp sanitary pumps. The MCCs then feed the various pumps, valves, motors, transformers, panels, etc. at the facility. **Table 1.12** provides a summary of the major electrical equipment for this facility.

Table 1.12 – Oakwood Electrical Details

Location	Major Electrical Equipment	Description
Electrical Room	Double ended 4.8 kV switchgear with automatic source transfer	3,000 A, 4.8 kV, 3-Phase
Electrical Room	VFD (Storm Pumps)	(4) 4.8 kV, 3-Phase
Storm Pump Motor Room	Vertical mixed flow pumps	(2) 1,500 hp, (6) 2000 hp, 4.8 kV, 3-Phase
Outdoors	Pad Mount Transformers	(2) 2,500 kVA, 4.8 kV-480 V, 3-Phase
Electrical Room	Double ended switchboard w/ tie-breaker	3,200 A, 480 V, 3-Phase
Electrical Room	VFD (Sanitary Pumps)	(4) 480 V, 3-Phase
Sanitary Pump Room	Sanitary Pumps	(4) 125 hp, 480 V, 3-Phase
Electrical Room	MCC-1	1,200 A, 480/277 V, 3-Phase
Electrical Room	MCC-2	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-3	1,200 A, 480/277 V, 3-Phase
Screening Facility Control Room	MCC-4	1,200 A, 480/277 V, 3-Phase

1.4.2.9 Instrumentation and Controls

Control System: The original Ovation control system was installed in 2012 under PC-755. In 2015 under PC -773D, the Ovation control system controllers and software were upgraded to version O.V.3.5.0.

The existing Ovation system includes remote I/O cabinets located in the Headworks/CSO Basins that are networked to the Ovation controller/I/O cabinets and data concentrator cabinet located in the Communication Room. The system currently has one dual screen operator workstation, plus a database server with wall mounted displays and printers in the Control Room. The Ovation redundant pair of controllers provides the facility with a redundant network, controls and I/O capabilities. A 10 kVA Liebert uninterruptible power supply is used to provide constant power to the Ovation system and network. The Ovation network is equipped with primary and backup network switches. The switches are connected to the GLWA AT&T wide area network via the facility's router. The network connections inside the station are via copper Ethernet cables. All workstations and controller connections have redundant networks. The controller connections are dual-homed to provide system redundancy. Should one network fail, the backup, redundant network is available to provide station monitoring and control. The Ovation system is equipped with a backup radio system to communicate critical monitoring points back to the SCC on wide area network failure.

Flow and Level Sensors: Table 1.13 summarizes the level sensors and flow meters at the Oakwood CSO Facility and Pump Station for monitoring flows through the treatment system, chemical dosing, and chemical storage tanks levels.

Table 1.13 – Oakwood Flow and Level Sensors Details

Area	Quantity	Instrument Type
CSO Flow Meters		
Storm Pump Flow Meters	8	Area Velocity
Drain to NWI Meter Vault	1	Magnetic
CSO Facility Level Sensors		
Screening Area	1	Ultrasonic
	1	Radar
Basin Influent (East and West)	2	Ultrasonic
	2	Radar
Basins (East and West)	2	Ultrasonic
	2	Radar
Basins Flush Gates (Gates 7, 8, 10, and 11)	4	Ultrasonic
NWI	1	Ultrasonic
Chemical System Flow Meters		
Chemical Feed	10	Magnetic
Chemical Storage Level Sensors		
Chemical Storage Tanks	2	Ultrasonic
Sanitary Pump Station Flow Meters		
Pump Meter Vault (East and West)	2	Magnetic
Pump Station Level Sensors		
Wet Wells (East and West, Upstream and Downstream)	4	Ultrasonic
Sanitary Surge Relief Chamber	1	Ultrasonic

1.4.2.10 Site Civil

Access to the site is off Pleasant Street through a 26-ft wide sliding vehicular gate. The parking lot consists of 8-in. thick reinforced concrete pavement. Roads onsite consist of 26 ft wide, 9 in. thick reinforced concrete pavement with 8-in. aggregate base designed to support HS-20 loading. There is also a gravel road around the CSO basin building consisting of 8 in. of aggregate. Concrete sidewalks are 4 to 5 ft wide and 4 in. thick with a 2-in. sand base. Site security is provided by a perimeter fence comprised of an 8-ft ornamental iron fence and an 8-ft chain-link fence. Stormwater runoff from the site is collected and conveyed to the storm junction chamber upstream of the pump station.

1.4.2.11 Architectural

Three buildings make up the Oakwood CSO RTB: The Storm Pump Station, screening building, and retention basins. These buildings include a chemical room, utility support, control room, odor control room, screen room, sampler room, storm pump room, sanitary pump room, hydraulic room, MUA room, shipping and receiving rooms, and other miscellaneous rooms.

1.4.2.12 Safety

Safety-related items include fall protection, exit signage, hatch access, handrails, and other miscellaneous items included throughout the facility.

1.5 Need for Project

The drivers for this project are focused on improving facility treatment reliability, flexibility, operation, maintenance, and safety features. These improvements will support planned increases in utilization/peak flow for both the Oakwood CSO RTB and Leib CSO SDF upon implementation of the selected alternatives identified by the study report (provided in Appendix A). Future projects planned by GLWA will impact the peak flow at these facilities. The Northwest Interceptor (NWI) connection will divert additional flow to the Oakwood RTB and to the Meldrum sewer connection will divert additional flow to the Leib CSO SDF. As a result of this additional flow improvements will be needed to avoid potential water quality compliance issues. Improvements to the disinfection systems will be needed at both facilities to provide adequate disinfection to the new CSO. Screening improvements at the Leib facility is needed to prevent CSO sanitary debris from discharging into the receiving water body. Below is a list of the detailed needs by facility and discipline.

1.5.1 Leib CSO SDF Needs

The needs and issues were identified from meetings with operation and maintenance (O&M) staff and site visit and investigations. The following issues were identified related to each of the components making up the Leib CSO SDF.

1.5.1.1 Disinfection Needs

Chemical storage system. The WWMP recommended a diversion to the Leib SDF which will increase utilization at the facility. To prepare for larger flows, the chemical storage system needs to be improved.

The existing disinfection system has two sodium hypochlorite storage tanks of 10,450 gallons, which will not accommodate increased flows. To address this, the storage tanks will need to be replaced with larger tanks (two, 12,600 gallon tanks) to meet future collection system peak design storm demands. The original design had a peak storm volume of 225 MG and the future collection system is 367 MG. A new system must be right-sized to meet these anticipated future demands.

Chemical feed system. In addition to the desire to standardize on one type of chemical feed pumps between facilities and the desire to simplify chemical feed system where possible, the Leib chemical feed system has the following issues:

- Lack of flow-paced and total residual chlorine (TRC)-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding the appropriate dosage of sodium hypochlorite solution. To stay compliant with the NPDES permit, overfeeding hypochlorite is common.
- The chemical feed pumps are expensive to maintain and replace. The pumps and motors are difficult to remove from the containment area.

- There are 18 chemical induction mixers to distribute the hypochlorite into the flow that requires relatively frequent and costly maintenance. Their infrequent usage causes the seals to dry out between CSO events.
- The chemical feed piping is highly complex, with a high number of components, as depicted in **Figure 1.4**.
- Components of the chemical feed piping (e.g., valves) are inaccessible due to height on wall, as depicted in **Figure 1.4**.
- The VFDs and electrical equipment are located in the corrosive environment of the chemical room, accelerating equipment wear and tear.
- Currently, a hose must be moved and connected to each pump suction pipe to flush the hypochlorite solution from the feed system with non-potable water (NPW), as shown in Figure 1.2. A hard-piped flushing water connection is desired so that flushing could be accomplished by opening a valve to each pump.
- The chemical room floor has been damaged due to a chemical leak from one of the storage tanks.

Figure 1.4 – Leib CSO SDF Chemical Feed Pumps and Piping Manifold

1.5.1.2 Screening Needs

The technology for COPA screens has not changed in the last few decades and no improvement options exist except for the replacement of screens. These screens are difficult to maintain, frequently become blinded, and cleaning after storm events is labor intensive. There are no US representatives for spare parts, repair, or technical support, nor are there any other known successful installations in the US. No updates or improvements to the screen controls or operation have been made since the installation.

Due to these issues with the COPA screen, Romag is the preferred screening technology currently used at Leib and standardizing operations, maintenance, and replacement parts around Romag screens is preferred.

1.5.1.3 Instrumentation and Control Needs

As described under the Disinfection Needs section, there is currently no ability to monitor TRC or dosage requirements at Leib, which means that sodium hypochlorite solution is often overdosed to ensure adequate disinfection. As such, more robust and reliable TRC-based and flow-paced controls are desired to optimize sodium hypochlorite usage and prevent over- or under-dosing of disinfectant.

1.5.1.4 Flushing and Dewatering Needs

Manual flushing the screening channels after every storm event is difficult and time-consuming. Both the screenings channel and the screen influent channels accumulate significant volumes of screenings that must be manually cleaned between storm events but are difficult to access.

1.5.1.5 HVAC Needs

Access to supply fan SF-1 for maintenance and repair is difficult; there is very little clearance to service belts and bearings in the supply fan room. Additionally, in discussions with operations staff, a replacement of thermostat was identified as a need to provide an indication of the temperature in the office.

1.5.1.6 Electrical Needs

Operators need to call an electrician to reset the mixer units, which includes inherent delay for staff to travel to site to perform this activity.

1.5.1.7 Site Civil Needs

A new access roadway from Meldrum Street is needed due to safety concerns associated with the current entrance gate on Mt. Elliot Street, which is heavily trafficked with narrow shoulders. Vehicles must stop in the road or pull over to the narrow shoulder to allow time for the gate to open before entering.

1.5.1.8 Architectural Needs

The architectural needs include the following:

- Removal and reinstallation of chemical facility wall to accommodate sodium hypochlorite storage tank replacement.
- Wall modification, door removal, and new double door for SF-1 access.

- East and West vestibule modifications for NFPA 820 area isolation: provide required separation between hazardous classified spaces and unclassified spaces.
- Potential modifications to the chemical storage/feed room.

1.5.1.9 Safety Needs

The Leib CSO SDF lacks fall protection to allow safe access to appurtenances and valves above the sodium hypochlorite tanks. Fall protection is desired for safety.

Table 1.14 – Leib Safety Needs

Location	Description
Garage	No exit sign
Chemical Room	No guardrails on tanks
Chemical Storage Tanks	Fall Protection

1.5.2 Oakwood CSO RTB Needs

1.5.2.1 Disinfection Needs

The chemical storage system at Oakwood CSO RTB needs to be resized to meet increased peak demands. The currently storage tanks will need to be replaced with larger FRP tanks (15,000 gallons). The original design storage had a peak storm volume of 98 MG but will increase to 368 MG for the future collection system configuration to better reflect true disinfection needs established during the study phase of the design. The chemical feed system is at the end of its useful life and has several maintenance issues. In addition to the desire to standardize on one type of chemical feed pumps between facilities and the desire to simplify chemical feed where possible, the Oakwood chemical feed system has the following issues:

- The gear pumps are expensive to replace and repair.
- The gear pumps vibrate despite efforts to eliminate vibration.
- The chemical feed pumps are on skids. The skid frames reduce access to the pumps and components and do not aid in the removal of the pumps.
- Lack of flow-paced and TRC-paced automated chemical feed. Chemical feed system controls are O&M intensive and have performance issues with feeding appropriate levels of chemical. To stay compliant, overfeeding chemical is common.
- Corrosion concerns at chemical injection points on pump discharge.
- Desire for side access manway on hypochlorite tanks for improved ease of inspection and future relining.

1.5.2.2 Screening Needs

Water carry-over into screenings dumpster and onto floor near dumpster: Screenings and spray water from the screens are conveyed by the screw conveyor directly into the dumpster at ground floor. There is a significant amount of water that can completely fill the dumpster during an event if grinder is off-line and spills onto the floor around the dumpster. This phenomenon is depicted in **Figure 1.5**. A wheel mounted screenings washer/compactor/grinder (i.e., compactor) was provided in the original system

and can be moved into place to wash and compact the screenings. The compactor has a drain that can divert the excess water to a drain line. The compactor, however, was problematic because screenings fill the compactor chute, dry in place, and are unable to be pushed out of the chute during the subsequent storm. However, GLWA modifications to the compactor have resulted in its reliable operation. The excess water conveyed to the compactor remains a challenge if it is off-line, and thus reduction of the water conveyed by the conveyor is desired.

Figure 1.5 – Oakwood CSO RTB Screenings Dumpster Overflowing During Storm Event

1.5.2.3 Storm Pump Station Needs

The following needs were identified for the storm water pump station:

- A significant volume of drinking water is currently used for seal water. Reduction or elimination of drinking water used for pump seals is desired.
- Debris buildup results in plugging on lubrication grooves in bearings, which under a worst case scenario can cause seizing of pumps.
- Multiple pump components require replacement, including shaft sleeves, line shaft bearings, bowl bearings, rolling element bearings, discharge pressure gauges, and lip seals.
- A motor thrust bearing cooling water system is desired.
- Possibility for improvements to pump controls to improve efficiency and reduce maintenance. These are described under **Section 1.5.2.5**.

1.5.2.4 Sanitary Pump Station Needs

Similar to the Storm Pump Station, there is room for improvement of the pump controls to improve efficiency and reduce maintenance. These are described under **Section 1.5.2.5**.

1.5.2.5 Instrumentation and Controls Needs

The following instrumentation and controls needs were identified:

- There is room for improvement of the storm and sanitary pump controls and operating strategy. With the current controls, the starting storm pump cannot be manually selected by operators, and the wear and tear on each pump is thus not consistent. Manual selection will ensure that the operation of the pumps is more evenly distributed between the pumps. Additionally, monitoring the wet well level and incorporation into the pump controls will allow pumps to operate closer to their preferred operating range (POR), maximizing efficiency and reliability.
- Storm pump flow meters are beyond their service life and no longer provide reliable flow information.
- A backup flow measurement method is desired for each storm pump if the flow meter is not working properly.
- Vibration monitoring on the storm pumps is currently configured to trip alarms when vibration exceeds a peak of 0.85 in/sec, irrespective of the sensor location. This alarm is frequently tripped.
- Operators have indicated the human interface modules (HIMs) for the Chemical Feed Pump VFDs are difficult to operate locally.

1.5.2.6 Flushing and Dewatering Needs

The storm wet well flushing system requires modifications to facilitate improved flushing of settled debris from the sanitary trench and storm wet well after each wet weather event.

CSO Basin Flushing valves are hard to reach during maintenance activities and scaffolding needs to be setup to reach the valves, which is difficult due to steep slope on the floor.

Significant grit accumulation at the flushing sumps in the CSO basins leads to plugging of the 12-in. drainage pipeline at the effluent end of the basin.

1.5.2.7 Electrical Needs

The needs of electrical work at the Oakwood CSO RTB as part of this project are limited to supporting process, I&C, and plumbing improvements.

1.5.2.8 Site Civil Needs

Site civil needs at the Oakwood CSO RTB are as follows:

- The current road around the basin is gravel and susceptible to potholing.
- There are areas around the basin with poor drainage, including electrical and instrumentation vaults.
- There are several locations around the perimeter of the Control Building where the concrete access sidewalk has settled, leaving uneven cracked flags of sidewalk. Several of these areas corrected as part of an earlier project, but not all.

The following needs are generally preventative maintenance items intended to ensure that the site features or utilities are serviceable throughout their expected service lives:

- Clear vegetation overgrowth from Surge Relief Basin.
- Seal joints in concrete pavement drive to ensure serviceability.

1.6 Project Future Needs

This project will provide the necessary capacity for treatment and hydraulic passage of CSO events over the entire project life cycle in anticipation of the future connection of the Meldrum Sewer and Northwest Interceptor to the Leib and Oakwood CSO facilities, respectively. These treatment and flow requirements for each facility were established during the study phase of this project and are summarized in **Appendix A**.

Hydrographs through the Oakwood and Leib facilities were generated using the Regional Wastewater Collection System (RWCS) SWMM model. The RWCS model was developed under the Wastewater Master Plan (WWMP) Project for planning and decision-making purposes. The RWCS model provides a detailed representation of the wastewater collection system as it is today. The RWCS model was used for this project to provide design flow rates at the CSO facilities. The design events selected for this analysis were the 6-month, 24-hour and 10-year, 24-hour storm events.

The RWCS model was run for the design storm events for current and future conditions. Model predicted influent peak flow rates to each facility are summarized below in **Table 1.15** for current and future conditions at the Leib and Oakwood facilities based on present planning. Current conditions represents the wastewater collection system as it is today. Future conditions assumes the Meldrum connection to the Leib CSO SDF and the Oakwood District Intercommunity Relief Sewer (ODIRS)

connection to the Oakwood CSO RTB and Pump Station have been constructed and are in-service. The original facility design flow rates are also included in **Table 1.15** for comparison purposes.

The predicted peak flow rates presented in **Table 1.15** are based on 5-minute model output. The reporting time step of 5-minutes was selected under the Wastewater Master Plan Project to match meter time stamp data. The modeling effort for this project retained these parameters.

Table 3.1 – Flow Rate Comparison

Facility	Facility Original Design Flow Rate (cfs)	Collection System Conditions (Current or Future)	Predicted 5-minute Peak Flow Rate (cfs)	
			6-month, 24-hour Design Event	10-year, 24-hour Design Event
Leib CSO SDF	1,550 (Peak Design Flow)	Current	118	520
	2,000 (Hydraulic Capacity)	Future	380	950
Oakwood CSO RTB and PS	1,660 (Firm Capacity)	Current	135	765
		Future	531	1,231

2.0 Analysis of Alternatives

Much of the alternatives analysis that informed the design of this project were recommended as part of CS-299, which is included in **Appendix E**. For instances where the conceptual study identified additional alternatives based on revised project criteria and scope items, these alternatives are identified and discussed in detail in the technical memoranda included in the Study and Conceptual Design Report in **Appendix A**.

2.1 No Action

The No Action alternative involves maintaining current system operations. Since this project is intended to accommodate additional flows from the Meldrum diversion sewer and the NWI diversion sewer, the Oakwood and Leib CSO's risk exceeding their current design treatment and/or hydraulic capacities. Additionally, aging equipment will eventually fail and leave the facilities at risk of achieving inadequate treatment, causing sewer backups, operation, and maintenance issues, NPDES permit non-compliance, degraded water quality in receiving water bodies (the Rouge and Detroit Rivers) and additional problems. The objectives of the project are not met under the No Action alternative and are not in accordance with the recommendations of CS-299 or the conceptual design study performed by CDM Smith.

2.2 Optimum Performance of Existing System

Optimization of existing systems involves operational changes and equipment or personnel changes to achieve the goals of the project beyond construction or replacement alternatives. In general, this overall alternative approach is appropriate for specific systems in the CSO facilities but is not appropriate where equipment age and reliability is the primary concern. Major examples of optimization improvements are:

- Comprehensive monitoring, feedback, and control of total residual chlorine (TRC), tank/wet well level, facility flow rates, and pumped flow rates to better inform the optimal sodium hypochlorite dosage at each facility. Optimization of chemical usage will result in overall lower chemical usage and superior effluent quality.
- Modifications to the operating controls of the pumped systems at Oakwood CSO RTB to reduce energy, drinking water usage, and O&M costs.
- Replacement of chlorination mixers downstream of the screen effluent channels at the Leib CSO SDF with chemical feed drop pipes to distribute disinfectant significantly reduces energy and O&M costs associated with operating the mixers.

2.3 Regionalization

The improvements included in this project were identified based on the need to divert additional flows from nearby sewers to these CSO facilities to more fully utilize their capacity and optimize collection system operations in such a way that protects water quality and prevents sewer backups. While the

diversions themselves are not in the scope of this project, the facility improvements will be designed to accommodate these diverted flows and improve water quality treated effluent to CSOs.

The nature of the combined sewage network served by the Oakwood and Leib CSO facilities is that they are used to alleviate both hydraulic issues associated with local sewer subcatchments and mitigate water quality issues associated with existing combined sewer overflow events. Decommissioning these CSO facilities without significant investments to redirect flows exceeding the hydraulic capacity of the combined sewer or increasing the capacity of the combined sewer downstream of each facility would result in uncontrolled and untreated CSO events. Thus, decommissioning these facilities is not an option considered as part of this project.

2.4 Monetary Evaluation

A monetary evaluation of alternatives for this project was performed as part of CS-299 and was used as the basis for selecting the recommended alternatives provided in that document, which were in turn incorporated into this project. Other alternatives were evaluated during the study phase of this project, in which a monetary evaluation was also performed and are provided in the Study and Conceptual Design Report.

2.4.1 Sunk Costs

Sunk costs are the investments or financial commitments made before or during project planning. These costs are not included in the cost-effectiveness analysis since they have already been committed regardless of the alternative selected. Sunk costs typically include the cost of existing facilities and land, outstanding bond indebtedness, and the cost of preparing the project planning document.

As described in **Section 2.3**, these CSO facilities cannot be relocated or decommissioned, and is thus not considered in this analysis.

2.4.2 Present Worth

The present worth of the construction of this project is calculated as follows:

$$PW = F * \frac{1}{(1 + i)^n}$$

Where:

F = Future Value = Estimated construction cost = \$44,000,000

PW = Present worth of one – time expenditures

i = Discount rate = 2.2%

n = Number of years = 3.8 years to construction mid – point.

The real discount rate was determined from the Federal Office of Management and Budget (OMB) from Appendix C of OMB Circular A-94 for a 3-5 year analysis. The number of years is calculated based on the time from present day (April 2024) to the anticipated mid-point of construction, estimated as 1/27/2028, which is 3.8 years. This results in an estimated present worth of \$41,000,000.

O&M costs associated with these improvements are expected to decrease significantly from their present values and are generally consistent between alternatives, thus not considered as part of alternatives analysis.

2.4.3 Salvage Value

The only work which may produce any meaningful substantial salvage value includes the removal of the COPA screens at Leib, which are made of stainless steel, and the removal of the existing chemical feed pumps at Oakwood, which contain Hastelloy heads/gears. Due to the highly specific sizing and applications of this equipment, it is assumed that they cannot be resold and only have value as scrap metal. Relative to the overall construction costs, these salvage values are insignificant and are thus not included in the monetary evaluation of alternatives.

2.4.4 Escalation

Escalation in the monetary evaluation for SRF loan approval is limited to energy costs and land value. As described in **Section 2.3**, these facilities cannot be relocated and the value of the land is not considered as it cannot be sold. In general, the energy savings associated with the project improvements are far outweighed by savings from reduced maintenance, reduced water usage, optimized chemical usage, and improved equipment reliability as a result of the infrequent operation of the facilities. Additionally, energy usage is considered to be similar between the evaluated alternatives.

2.4.5 Interest During Construction

Interest during construction was assumed in the most recent Opinion of Probably Construction Cost (OPCC) as 5 percent per year and is included in the overall project cost calculation. It was assumed for the purposes of alternatives analysis that all evaluated alternatives will result in similar construction schedules and thus similar interest rates.

2.4.6 User Costs

The cost to users is determined based on the duration of the SRF loan and overall project cost, as described in **Section 3.8**. Refer to that section for details on the end costs to users.

2.4.7 Project Delivery Method

The project delivery method for this project is traditional design-bid-build.

2.5 Environmental Evaluation

All improvements proposed within this project plan will be made to existing wastewater infrastructure at existing treatment facilities. Additionally, the construction methods are expected to have minimal environmental impact. Soil erosion and sediment control measures are included in the capital cost of the project and enforced during construction. Efforts will be made to mitigate and minimize construction noise and interruptions to traffic.

3.0 Selected Alternative

3.1 Summary

The work associated with the improvements at the GLWA Oakwood RTB and Leib SDF are required to address the disinfection, flushing, electrical, and instrumentation and control systems, and site improvements at both facilities, as well as HVAC and structural/architectural improvements needed to support the process modifications. This section contains a high-level summary of the work to be performed at each facility.

3.1.1 Leib CSO SDF

- Flow-paced and TRC-paced chemical feed control system.
- New chemical feed pumping and piping.
- New sodium hypochlorite storage tanks.
- Model disinfection performance and replace/remove chlorination mixers as feasible.
- Screening chamber flushing system improvements.
- HVAC and Architectural Improvements needed to comply with code requirements.
- Replacement of COPA screens with new Romag screens and rehabilitation of existing Romag screens.
- Site Improvements including alternate drive/gate access.
- Addition of process cameras.
- I&C and electrical improvements need to support process improvements.

3.1.2 Oakwood CSO RTB

- Flow-paced and TRC-paced chemical feed control system.
- New chemical feed pumping and piping.
- New sodium hypochlorite storage tanks.
- Modification of storm pumps to improve reliability.
- Storm pumps and sanitary pumps operational strategy improvements.
- Improved measurement of basin influent flow with Doppler flow meters.
- Screw conveyor drainage improvements.
- Improvements to the flushing valves and addition of basin drain sump flushing systems.
- Site improvements including improved drainage, onsite access roads and sidewalk repair.
- Elimination of cast-in-place steps in sanitary wet well influent channels.
- I&C and electrical improvements need to support process improvements.

3.2 Design Parameters

3.2.1 Design Criteria

Design criteria for the Oakwood and Leib CSO Control Facility Improvements are provided in **Table 3.1**. The anticipated flows for both facilities were developed based on storm hydrographs associated with each influent sewer and developed with the future Meldrum Sewer and NWI diversions to Leib and Oakwood CSO facilities, respectively, in service.

Table 3.1 – Design Criteria for Oakwood and Leib CSO Facility Improvements

Design Criterion	Leib CSO SDF	Oakwood CSO RTB
Treatment Capacity	950 cfs	1,231 cfs
Hydraulic Capacity	2,000 cfs	1,660 cfs
Design Storm Event 1	6-month 24-hour storm	6-month 24-hour storm
Design Flow Rate	380 cfs	531 cfs
Design Storm Volume	54 million gallons	92 million gallons
Design Storm Event 2	10-year 24-hour storm	10-year 24-hour storm
Design Flow Rate	950 cfs	1,231 cfs
Design Storm Volume	367 million gallons	368 million gallons
Screening		
# of Screens	8 (4 existing to be rehabilitated, 4 new)	6 (existing)
Screen Manufacturer / Type	Romag (deflection bar screen)	Andritz (perforated panel)
Screen Opening Size	4 mm	6 mm
Screen Capacity	158 cfs (each)	277 cfs (each)
Sampling and Monitoring		
# of Sampling Pumps	2 (new)	7 (new)
Pump Type	Submersible	Submersible
Disinfection		
Disinfection Contact Volume	6.5 million gallons	9 million gallons (total)
Design NaOCl Solution Strength	10.0 mg/L to 15.0 mg/L	5.0 mg/L to 15.0 mg/L
# of NaOCl Solution Storage Tanks	2 (new)	2 (new)
NaOCl Solution Storage Volume	15,000 gallons (each)	12,600 gallons (each)
Design NaOCl Dose	6.3 to 11.1 mg/L	7.4 to 14.0 mg/L
# of Recirc and Chemical Feed Pumps	3 (new)	4 (new)
Pump Type	Centrifugal, sealless mag-drive	Centrifugal, sealless mag-drive
# of Chemical Mixers	2 (existing)	N/A
Flow Retention		
# of Retention / Contact Basins	N/A	2
Retention Basin Volume	N/A	4.5 million gallons (each)
Storm Pumps		
# of Storm Pumps	N/A	8 (existing to be modified)
# of thrust bearing cooling water booster pumps	N/A	8 (existing)
# of grease lubrication central stations	N/A	8 (new)

Design Criterion	Leib CSO SDF	Oakwood CSO RTB
CSO Basin Solids Suspension Pumps	N/A	2 (new)

3.2.2 Flow Schematics

Existing schematic flow diagrams of the treatment processes at each facility are presented in **Figure 3.1**, **Figure 3.2**, and **Figure 3.3**. In general, the improvements associated with this project will not change the flow path through the facilities, with the following exceptions:

- New locations for TRC monitoring and sampling pumps.
- Slightly modified flow path for the new Leib screens – flow through the existing COPA screens moves vertically upward through the screen before flowing over the screen effluent weirs, while flow through the horizontal Romag screens moves horizontally through the screens and over the screen effluent weirs. Per the proposed improvements, all screening will be through the horizontal Romag screens.
- New chemical storage and feed systems, for which proposed new flow schematics are provided in **Figure 3.4** and **Figure 3.5**.

Figure 3.1 – Existing Oakwood CSO RTB Flow Schematic – Upstream End

Figure 3.2 – Existing Oakwood CSO RTB Flow Schematic – Downstream End

Figure 3.3 – Existing Leib CSO SDF Flow Schematic

Figure 3.4 – Proposed New Oakwood CSO RTB Chemical System Flow Schematic

Figure 3.5 – Proposed New Leib CSO RTB Chemical System Flow Schematic

3.2.3 Soil and Erosion Control

Site and erosion plans for each facility are provided in **Figures 3.6** and **3.7**.

Figure 3.6 – Leib Site and Erosion Plan

Figure 3.7 – Oakwood Site & Erosion Plans

3.2.4 NPDES Permit Requirements

The current NPDES Permit No. MI0022802, provided in **Appendix B**, authorizes combined sewer overflow discharge from the Oakwood CSO RTB and the Leib CSO SDF, requiring the daily monitoring and reporting of effluent flow, as well as reporting effluent carbonaceous biochemical oxygen demand (CBOD₅), total suspended solids (TSS), ammonia nitrogen (NH₃-N), and total phosphorus (TP), fecal coliform bacteria, pH, and dissolved oxygen. Both facilities must meet a fecal coliform limit of less than or equal to 400 counts per 100 mL from May 1 to October 31, and less than or equal to 1,000 counts per 100 mL from November 1 to April 30. The Oakwood CSO RTB is also required to report oil and grease concentrations during each storm event as well as daily influent flow to the RTB.

The permit also includes a TRC minimization program which provides operational goals for the CSO facilities of 1.5 mg/L TRC as an event average value and 2.0 mg/L (November through April) or 3.0 mg/L (May through October) TRC as an event instantaneous maximum value at each facility. The improvements to chemical feed, monitoring, and controls proposed as part of this project are designed to meet or exceed these operational goals.

3.2.5 Existing Sewer and Future Connections

The Leib CSO SDF intercepts combined sewage from the Mt. Elliot Sewer, a 16-ft 3-in diameter sewer tunnel running below Mt. Elliot Avenue in Detroit. Treated effluent from this facility re-enters the Mt. Elliot Sewer, which provides disinfection contact time prior to discharge at the CSO outfall in the Detroit River. The improvements to the Leib CSO SDF proposed in this project are in response to the planned installation of a new 5-ft diameter sewer, the “Meldrum Diversion Sewer”, below Waterloo Avenue, which will divert flow to the Leib CSO SDF from the 9’ diameter Meldrum Sewer below Meldrum Avenue.

The Oakwood CSO RTB intercepts flow from several sewers near the Oakwood Pumping Station located approximately one and a half miles from the WRRF. Excess flow Northwest Interceptor (NWI) will be diverted to the Oakwood CSO RTB as part of the recommendations from Wastewater Master Plan Update, which has available treatment capacity under the design 10-year 24-hour storm flow event. The improvements to the Oakwood CSO RTB proposed in this project will enhance reliability and provide upgrades to facilitate conveyance and treatment of this additional flow to the facility.

3.3 Proposed Improvements

3.3.1 Common or Similar Improvements at Oakwood and Leib CSO Facilities

3.3.1.1 Disinfection Improvements

Proposed improvements include replacement and reconfiguration of the sodium hypochlorite storage and feed systems at each CSO control facility. The existing chemical feed systems are at the end of their useful life and the new systems will be designed in response to usage requirements determined through influent sampling and disinfectant dose response curves at each facility developed in the study phase of the project.

The new chemical storage and feed systems will include new centrifugal chemical feed pumps, feed control valves, the addition of a recirculation manifold to the chemical feed control valves, new piping,

equipment support pads, and new storage tanks. These new systems will be right-sized for the chemical doses determined in the study phase of this project, and will improve to equipment and process piping to facilitate O&M.

3.3.1.2 Instrumentation and Control Improvements

Each facility will be outfitted with new sampling systems to enable real-time monitoring of TRC during storm events, and new control systems to optimize the chemical feed rate in response to this monitoring. The improvements will include a flow-paced control system that matches the chemical feed rate to the combined sewage flow to each facility, as well as establishing feedback-based dosage requirements based on effluent TRC. This new monitoring instrumentation, process equipment, and controls will be integrated with the existing Emerson Ovation DCS platform used at GLWA facilities.

3.3.2 Leib CSO SDF Improvements

3.3.2.1 Screening Improvements

At the Leib CSO SDF, the existing COPA screens will be replaced with new Romag screens. This will require structural modifications to the screen channels. The channel wall openings will be lowered to accommodate the new screen design thru-bar velocity requirement provided by Romag as we coordinated the design improvements. Additionally, Concrete stairs located in the screen inlet channel bottom slabs will be removed and replaced with stairs with much longer treads, strategically placed sidewall and riser fillets to balance the maintenance access needs of the screens with the reduction of effort for post-event flushing.

3.3.2.2 Chemical Distribution Improvements

CFD modeling of chemical mixing through the Leib CSO SDF indicated that adequate distribution of disinfectant in the combined sewage could be maintained by replacing the sixteen sodium hypochlorite mixers downstream of screening with single-point chemical addition drop pipes located immediately downstream of the Romag screens in the screen outlet channels. This will reduce energy costs associated with operation of the mixers, as well as significantly reduce mixer maintenance costs. The existing mixers can be salvaged or kept for replacement of the remaining pre-chlorination mixers.

3.3.2.3 Flushing and Cleaning Improvements

At the Leib CSO SDF, a new flushing system will be provided at the downstream end of each screen inlet channel and at upstream end of the screenings collection channel to minimize cleaning requirements after wet weather events. These screenings are flushed into the Toward Treatment Sewer, which continues to the WRRF.

The existing concrete steps in the screen influent channels accumulate significant amounts of screenings after a storm event, requiring difficult and time-consuming cleaning. The accumulated screenings also present a safety hazard if the stairs are climbed. Thus, these steps will be replaced with a smooth concrete slope such that uncaptured screenings are conveyed to the Toward Treatment Sewer when the storm flows subside.

3.3.2.4 Ancillary Improvements

Ancillary improvements at Leib are as follows:

- A new access road will be constructed, providing vehicular access from Meldrum Street east of the facility. This new access drive will include fencing and security, and displaced parking will be relocated.
- Bioswales will be added or expanded to improve drainage around the facility and accommodate the increased runoff from the impervious paving added to the site.
- New soft starters will replace the existing soft starters to allow for manual and virtual resetting when a starter is tripped for the two remaining mixers at Leib, simplifying and streamlining operations.
- To provide improved maintenance access to the supply fan, the Supply Fan Room will be enlarged by creating an opening in the east wall of the room, adding a room extension with a ceiling, and adding a set of double exterior doors to allow for future replacement. Per operator recommendations, the wall-mounted thermostat on the ground floor will be replaced to provide a visual indication of the temperature.
- Process cameras will be installed to enhance site security and process monitoring.

3.3.3 Oakwood CSO RTB Improvements

3.3.3.1 Pumping Improvements

The storm pumps at the Oakwood CSO RTB will be modified to extend their service life, optimize energy efficiency, and reduce maintenance requirements. These modifications will include the replacement of shaft sleeves, line shaft bearings, and bowl bearings. Additionally, individual grease lubrication pump central stations will be provided for each storm pump, eliminating the use of seal water and providing substantial savings in the cost of drinking water used at the facility. Cooling water will be supplied for the thrust bearings to extend equipment life and improve reliability.

3.3.3.2 Instrumentation and Control Improvements

For both the storm pumps and the sanitary pumps, the pump control system will be modified to optimize energy usage and maximize equipment service life.

The existing Oakwood CSO RTB storm pump discharge (basin influent) flow meters are past their useful design life and no longer produce usable flow data and thus will be replaced. Each of the eight existing meters will be replaced with advanced Doppler insertion meters in each of the storm pump discharge pipes. As a backup to this system, influent flow rate can be estimated by Ovation algorithm based on storm wet well level, pump run status, and pump speed (for VFD speed controlled pumps) from Ovation, using the storm pump performance curves. This secondary flow measurement method can be used to check the insertion flow meter output and can serve as a method of estimating flow if the insertion meters are out of service during a wet weather event. These flow measurements will be critical to the flow-paced sodium hypochlorite disinfection controls.

Redundant non-contact level sensors will be added to the wet wells to provide more reliable level measurements that provide valuable real-time operation and control data.

3.3.3.3 Flushing, Cleaning, and Dewatering Improvements

Improvements to the flushing systems at the Oakwood CSO RTB include the addition of pumps in the retention basin to provide recirculation and minimize the accumulation of sediment in the sump after a wet weather event.

Issues with the high volume of water conveyed to the screenings grinder/washer/compactor and screenings dumpster will be addressed by providing three drain sections and drain boxes in the screenings conveyor to minimize the volume of water included in the material conveyed to the grinder.

3.3.3.4 Ancillary Improvements

Ancillary improvements at the Oakwood CSO RTB are as follows:

- Under certain basin level and flow conditions, existing stairs in the sanitary pump station wet well influent channel create a cascade that entrains air into the sewage and releases foul odors and corrosive sewer gases into the air. To mitigate this phenomenon, the stairs will be replaced with a smooth concrete slab that permits the smooth surface for flow to be conveyed down into the sanitary wet well influent channel.
- The perimeter road around the CSO Retention Basins will be repaved according to MDOT standards for HS-20 loading per the recommendations from the geotechnical report (**Appendix F**). The repaved road will be provided with a shoulder on the outer edge of the road, as well as improved signage, bollards, and wider turning radii to facilitate large vehicular traffic around the site and improve safety.
- The storm and sanitary pump wells and influent tunnels will be cleaned as part of this project construction to facilitate access for construction.
- Bioswales will be added or expanded to improve drainage around the facility and accommodate the increased runoff from the impervious paving added to the site.

3.4 Useful Life

The design life of project is determined using a weighted average, calculated as the sum of each asset's dollar value times its estimated useful life, divided by the total estimated dollars spent on assets. The design life of the project is expected to exceed 20 years, but not 30 years. Thus, a 30-year SRF loan is requested.

3.5 Project Maps

Graphics showing the locations of the Leib CSO SDF, the Oakwood CSO RTB, and the WRRF are shown in **Figures 1.1, Figure 1.2, and Figure 1.3**. All work associated with this project will occur at the Leib CSO SDF and the Oakwood CSO RTB sites.

3.6 Water and Energy Efficiency

Specific components of this project are explicitly intended to improve energy and water usage efficiency and provide associated cost savings. In particular, the changes in pump operation at the Oakwood CSO RTB and the replacement of the chlorination mixers at the Leib CSO SDF are intended to provide energy savings. Improvements to the flushing systems at Oakwood will likely reduce the water use required to clean and flush the retention basins between wet weather events. Additionally, replacing the existing seal water systems for the Oakwood CSO RTB with grease lubrication systems will significantly reduce use of water. Changes at both Oakwood and Leib CSO facilities regarding total residual chlorine monitoring and sodium hypochlorite dosing are intended to improve the efficiency of chemical use.

3.7 Schedule for Design and Construction

A preliminary schedule for design and construction of the selected alternatives is presented in **Table 3.2**:

Table 3.2 – Proposed Project Schedule

Project Milestone Description	Actual/Projected
Design Contract Start	9/16/2022
Construction Document Ready for Bid	12/13/24
Construction Notice to Proceed	10/27/25
Construction Substantial Completion	2/11/2030
Construction Final Completion	4/29/2030

3.8 Cost Summary

Construction cost for the rehabilitation of the Oakwood and Leib CSO facilities by the recommended rehabilitation method is estimated to be \$44,000,000, which is a Class 2 estimate for budgetary purposes as defined by the American Association of Cost Engineering International. The cost carries an expected accuracy range of (-) 10% to (+) 15 percent.

In addition to the construction cost, the total project cost also includes:

- Design: \$8,600,000
- Construction Administration: \$1,700,000

The total project cost is \$55,000,000, rounded to the nearest \$1 million.

The CWSRF loan is anticipated to be financed for a 30-year term at 2.75 percent interest. The equivalent annual cost for this project is determined using the following equation:

$$A = PW * \left[\frac{i * (1 + i)^n}{(1 + i)^n - 1} \right]$$

Where:

A = Equivalent Annual Cost

PW = Present Worth = Total Project Cost = \$55,000,000

i = SRF Interest Rate = 2.75%

n = Term of SRF Loan = 30 years

Therefore, the equivalent annual cost is \$2,700,000.

The number of persons per household in Michigan was estimated by the United States Census Bureau as 2.47 in 2019. The estimated number of households that will be impacted by this project is estimated to be 1.16 million. The per household unit cost is thus \$2.34 per year.

3.9 Implementability

The Oakwood and Leib CSO control facilities are owned and operated by GLWA. GLWA is a regional utility with broad statutory authority. GLWA has entered contracts with its suburban customers, which establish the terms and conditions for receiving and treating wastewater and overseeing the operation and maintenance of the system. GLWA has substantial experience in the financing of capital improvements under a variety of programs. It has a proven track record for using system revenues to retire its debt on new facilities and projects. GLWA is responsible for the legal, financial, and managerial aspects of the Oakwood and Leib CSO control facilities and will be the loan applicant for the proposed project.

4.0 Environmental and Public Health Impacts

Formal contact with SHPO, THPO, USFWS, MNFI, and EGLE Water Resources Division will be made to review potential beneficial and adverse effects of the project to the environmental and/or public health.

4.1 Direct Impacts

Direct impacts are environmental impacts directly attributed to the construction and operation of the project. The effects of the proposed project on environmental factors have been analyzed.

The CSO facilities project will not have many direct impacts to the environment and public. In general, the project is creating improvements to the existing site and impacts to the environmental and public will be minimal and confined.

For both project sites, disturbance of traffic patterns, including detours, may be experienced. Additionally, the estimated cost per household annual user cost is \$2.43 per year.

4.1.1 Leib Direct Impacts

A new site access from Meldrum Street is proposed for the Leib CSO SDF. The construction of a new access road will include a 24-ft wide access drive and will be 175-ft off Meldrum Street. This will also include paving of Mt. Elliot in front of the Leib facility. The construction of a new access road may lead to soil disruption and drainage issues during excavation. Increased traffic could also contribute to localized air pollution, impacting air quality and respiratory health. Additionally, temporary traffic control near Meldrum Street could raise safety concerns for pedestrians and drivers. Mitigation measures are crucial to address these direct impacts and will be reviewed in **Section 5**.

4.1.2 Oakwood Direct Impacts

Improvements at the Oakwood CSO facility include adding paved roads around the basin, addressing drainage around the CSO Basin with green stormwater infrastructure featuring bioswale, addressing drainage in the electrical and instrumentation vaults, and replacing the settled concrete sidewalk. These improvements will have direct impacts on both the environment and construction site. Excavation for the paved roads and drainage may disturb soil and alter natural drainage patterns, necessitating erosion control measures to prevent sediment runoff. In addition, traffic on the project site may be impacted. The replacement of the settle concrete sidewalks will involve demolition and reconstruction activities, potentially generating noise and dust. Mitigation measures are crucial to address these direct impacts and will be reviewed in Section 5.

4.2 Indirect Impacts

Indirect impacts resulting from the proposed project include temporary impacts to air and noise pollution. The most significant air quality impacts are associate with construction debris and dust. Additionally, heavy equipment and construction noise may pollute surrounding areas outside the sites. Temporary changes to the natural environment and aesthetics of the area during construction will be restored upon completion. Because the proposed project is confined to previously constructed sites, there are no anticipated impacts to the following:

- Changes in the rate, density, or type of development (residential/commercial/ industrial).
- Changes in land use (i.e., open space, floodplains, prime agricultural land, shorelands, forested areas, or other natural habitats).
- Changes in water quality due to facilitated development.
- Impacts on cultural, human, social, and economic resources.
- Resource consumption over the useful life of the project.

4.3 Cumulative Impacts

Cumulative impacts are those impacts to the environment which increase in magnitude over time, or those which result from individually minor but collectively significant actions taking place over time. There are no anticipated cumulative impacts that would increase over time.

5.0 Mitigation

Where impacts cannot be avoided, mitigation measures will be taken. These are described in the following sections.

5.1 Mitigation of Short-Term Impacts

The most significant short-term impacts will be on the surface and subsurface where excavation will take place for the installation of the new sidewalks and access roads. Many mitigation techniques can be used to minimize construction impacts, including traffic and safety hazard control, dust control, noise control, and soil erosion and sedimentation control. Each of these will be included within the construction contract. Restoration and/or replacement of roads, vegetation, and utilities will also be handled within the construction contract.

5.2 Mitigation of Long-Term Impacts

It is not anticipated that there will be any long-term impacts at either of the construction sites.

5.2.1 General Construction

Mitigation measures would be developed to ensure that sensitive environments will not suffer permanent damage. In locations proposed for construction, permits will be obtained, and complete mitigation measures outlined within the permit will be adhered to.

5.2.2 Siting Decisions

Aside from the proposed new access road to Meldrum Street at the Leib CSO SDF, all improvements will be made at the existing CSO control facilities within the footprint of the existing sites.

5.2.3 Operational Impacts

No new operational impacts are expected aside from improvements to discharge effluent quality and operator safety. Operation of the upgraded facilities are expected to improve effluent discharge quality. Odors, aerosols, and noise were not identified as major issues with these facilities and the upgrades included in this project will not affect these. Several upgrades will be made to facility safety. Potential releases of hazardous chemicals (i.e., sodium hypochlorite solution) are already addressed in the facilities operation plan for the current chemical feed system and will not need to be modified.

5.3 Mitigation of Indirect Impacts

The proposed projects do not involve expansion of the facilities or implementation of a new treatment facility. The proposed work will not influence the rate of development, population density, zoning, or land use. Therefore, no direct impacts are foreseen as a part of this project.

6.0 Public Participation

6.1 Public Meeting

A Public Hearing for the Oakwood/Leib Project Plan was held on April 10, 2024, at the GLWA Water Board Building, online via Zoom Video conferencing, and through telephonic hearing. The intent of the Public Hearing meeting is to discuss the need for the project, principal alternatives, environmental impacts, description of the recommended alternative, and associated cost estimates and user charges, and scheduling of the proposed project.

A copy of the public hearing transcript is included in **Appendix D**.

6.2 Public Meeting Advertisement

The Public Hearing was advertised (online, paper, etc.) on month, day, 2024, XX days before the hearing date in accordance with SRF guidelines. Copies of the draft project plan detailing the proposed project were available for the inspection on March 27, 2024. The Public Hearing Notice is included in **Appendix D**.

6.3 Public Meeting Summary

The following topics were discussed at the public hearing:

- Project background.
- A description of the existing facilities.
- A description of the principal project alternatives that were considered.
- A breakdown of capital costs and O&M costs for each alternative.
- Proposed method of financing.
- Comparison of environmental impacts for the principal alternatives.
- The recommended alternative.
- Proposed monthly user costs for the implementation of the recommended alternative for the average residential customer.

7.0 Technical Considerations

As the scope of this project work is limited to the CSO facilities and does not contain any elements relating to infiltration and inflow removal, sewer system evaluation, structural integrity of sewer lines, a fiscal sustainability plan, or special assessment district properties.

Executive Summary

The selected alternatives or major decision made during the Conceptual and Study Phase as documented in this report are summarized in **Table ES-1**. The decisions are organized by technical memoranda number.

Table ES-1: Major Decisions from the Conceptual and Study Phase

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Recommended design storms and design flow rates as defined in TM-1 appendix	Facility Hydraulic Models	1		X		X		Review comments on Design Storm Event and Facility Flow Rate Summary memo (TM-1 Appendix A)
One construction contract for storm pump work + remaining work of this project.	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop
Recommended two storm pumps be rehabilitated at a time based on the historical records showing no more than five pumps in operation for large wet weather events, See TM-15 Section 3.	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X				Based on Key Decision Table GLWA comment, added recommendation for number of storm pumps to be rehabilitated at one time in TM-15, where backup/basis located.
Feasible to flush storm wet well after each event	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop
Sanitary pumps will not be used during wet well cleaning process by outside contractor	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Storm pump rehab/modification: CDM Smith proposed pump mfrs for rehab acceptable; one grease lube system per storm pump; grease lube system to be located on motor room level; connect the one existing grease lube bearing to new grease lube system.	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 and 5/3 Workshops, final location of grease lube system on motor level to be vetted during BOD phase
Cooling water disposal alternative B acceptable but will require sump pump backup with a second pump (backup pump above the sump)	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 and 5/3 Workshops
Remove cooling water booster pump (storm pump motor thrust bearing cooling)	Storm Pump Rehab & Wet Well Cleaning	2		X		X		5/24 meeting, Agree if path forward demonstrates sufficient pressure with not even one excursion. CDM Smith Recommends removal if water pressure monitoring demonstrates consistent adequate water pressure
Storm pump rehab (grease lube system considered modification) to include replacement of line shaft bearings, bowl bearings and likely the shaft sleeves	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Cleaning methods and constraints identified in the specification for cleaning as part of this project to be patterned after the recent Pullman led cleaning work. Access to the wet well would not be modified as part of this project.	Storm Pump Rehab & Wet Well Cleaning	2		X	Recommend following similar procedures with exception of no sanitary pump use.	X		GLWA agreement during 4/19 Workshop
ST-5 be removed for rehab and grease lube modifications for work to be performed at pump manufacturer's facility.	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop
Grease lube system modification to each storm pump to be performed as part of this project.	Storm Pump Rehab & Wet Well Cleaning	2		X		X		GLWA agreement during 4/19 Workshop
Only one stair, which aerates wastewater under certain operating conditions, requires modification, the other two stairs do not require modification.	Sanitary PS Concrete Stair Mod. Evaluation	3		X		X		GLWA agreement during 4/5 Workshop
Stair C (in sanitary influent channel upstream of screen) modifications to include stair removal and replacement with sloped concrete ramp.	Sanitary PS Concrete Stair Mod. Evaluation	3	X		Concluded this is the stair observed aerating flow, requires removal	X		GLWA input received during 4/19 workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
OKW SCR-2 Addition of drain boxes to the conveyor trough to move forward into next design phase	Oakwood Screw Conveyor & Grinder System Modifications	4	X			X		GLWA agreement during 4/19 and 5/3 Workshops
OKW SCR-2 GLWA will continue to use the existing grinder	Oakwood Screw Conveyor & Grinder System Modifications	4	X			X		GLWA agreement during 4/19 and 5/3 Workshops
No change to screen cleaning washwater pressure	Oakwood Screw Conveyor & Grinder System Modifications	4		X		X		GLWA agreement during 4/19 and 5/3 Workshops
There are no further modifications to the vertical screenings chute needed	Oakwood Screw Conveyor & Grinder System Modifications	4		X		X		GLWA agreement during 4/19 and 5/3 Workshops
All-Romag screen alternative selection assuming operating in accordance with screen manufacturer recommendations	Leib Screening Evaluation	5	X		Determine to be technically feasible (hydraulics evaluated in detail)			HOLD: mfr coordination on recently indicates thru-screen velocity ongoing
All-Romag screen alternative to be provided in one phase or two phases (replace Copa screens in one or both channels as part of this project)	Leib Screening Evaluation	5		X				
OKW wet well level sensors will not be contact type.	I&C Improvements	7		X		X		GLWA agreement during 4/5 workshop and discussions with staff

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
OKW upstream and downstream wet well channels will each have redundant level sensors	I&C Improvements	7		X		X		GLWA agreement during 4/5 workshop
Leib DRI Level sensor (LIT3) is being replaced by GLWA project 2004538	I&C Improvements	7		X		X		Confirmation by GLWA on 4/12
OKW I/O expansion will be based on the Ovation platform	I&C Improvements	7		X		X		GLWA agreement during 4/5 workshop
Leib - SF-1 Maintenance Access - GLWA requested that a set of double doors be added to the exterior wall of the Supply Fan Room to allow for the removal of SF-1 in the future, as discussed in the TM Workshop.	Leib HVAC Improvements	8		X		X		GLWA agreement during 4/5 Workshop
Leib - SF-1 Maintenance Access - Alternate 2 - Enlarge Room by Creating an Opening in the East Wall of Supply Fan Room, and Adding Room Extension with Ceiling was selected during the TM Workshop as the best alternate. This alternate has been revised to include the double doors requested during the Workshop.	Leib HVAC Improvements	8	X			X		GLWA agreement during 4/5 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Leib - SF-1 Maintenance Access - The existing floor drain in the Garage located in the footprint of the Supply Fan Room extension shall be relocated and not abandoned per direction from GLWA provided in the review of the Draft TM-08.	Leib HVAC Improvements	8		X		X		GLWA comment during TM-8 Review
Leib - Office Temperature Controls - Alternate 2 - Replace Wall Mounted Thermostat was selected during the TM Workshop as the best alternate.	Leib HVAC Improvements	8	X			X		GLWA agreement during 4/5 Workshop
Leib - East and West Vestibule Connectivity Issue - Per the discussions that took place at the TM Workshop and with the CSO Manager, Alternative 2 was selected as the best solution, that provides adequate security and the desired weather protection.	Leib NFPA 820 Analysis	9	X			X		GLWA agreement during 4/5 Workshop and D. McCord 4/18 Meeting
Leib - East and West Vestibule Connectivity Issue - A bird screen is acceptable for the desired protection. A bug screen is not needed per discussions with the CSO Manager.	Leib NFPA 820 Analysis	9		X		X		GLWA decision during D. McCord 4/18 Meeting

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Leib - Odor Control Duct for Future Use Connectivity Issue - Per the discussions that took place at the TM and Preliminary Review Workshops, the Odor Control Duct shall be abandoned as noted above in this Technical Memorandum.	Leib NFPA 820 Analysis	9	X			X		GLWA agreement during 2/10 Conceptual Design Overview 4/5 Workshop
OKW-use of geogrid material under the pavement to bridge over the organic pockets	Survey and Site Constraints	11		X	Geotechnical report has been revised to include this as an alternative and confirmed technically feasible.	X		Requested consider this alternative at 4/5 workshop
Speed range changes for storm and sanitary pumps as presented in TM-15	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop
Changes to minimum wet well level (lead pump shutoff) for Storm pumps as summarized in TM-15	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop
Changes to overall control based on rising level setpoint for Storm pumps	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop
SN – Operation with one pump serving dry weather flow wet well level range in lieu of three	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
SN- speed constraints to maintain operation within AOR	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop
Changes to number of operating sanitary pumps as a function of wet well level.	Storm & Sanitary Pump Op. Strategies Imp. Eval.	15		X		X		GLWA agreement during 5/12 Workshop
Partitioning the chlorine demand/usage between first flush conditions and the balance of the storm event.	Chlorine Dose Response Results and ICT Model/Chlorine System Alternatives	18 / 20	X			X		GLWA agreement during 5/12 Workshop
Oakwood ICT values	Chlorine Dose Response Results and ICT Model/Chlorine System Alternatives	18 / 20	X			X		GLWA agreement during 5/12 Workshop
Leib ICT Values	Chlorine Dose Response Results and ICT Model/Chlorine System Alternatives	18 / 20	X			X		GLWA agreement during 5/12 Workshop
Base minimum SHC flow rate on minimum ICT value from the chlorine dose response testing performed to date and the minimum flow rate for each facility.	Chlorine Dose Response Results and ICT Model/Chlorine System Alternatives	18 / 20	X			X		GLWA agreement during 5/12 Workshop
Use colorimetric TRC analyzers and Swan as the manufacturer	Chlorine System Automation Evaluation	19	X			X		GLWA agreement during 5/12 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Agreement with means of controlling and optimizing the chlorine disinfection process: Manual Control, Flow Paced, ICT Dose Paced with TRC Analyzers, and Machine Learning (ML) Dosing model	Chlorine System Automation Evaluation	19	X			X		GLWA agreement during 5/12 Workshop
Chlorine Demand and Chlorine Decay sampling locations at Oakwood.	Chlorine System Automation Evaluation	19	X			X		GLWA agreement during 5/12 Workshop
TRC analyzer locations for Chlorine Demand and Chlorine Decay at Oakwood at Screen Facility (either roof of Screen Inlet Chamber or Mechanical Room of Screen Facility) will be evaluated during Basis of Design.	Chlorine System Automation Evaluation	19		X	Evaluate location of TRC Analyzer at either roof of Screen Inlet Chamber or Mechanical Room of Screen Facility) during Basis of Design	X		From 5/24 meeting, Agree if recommendation made in BOD phase, since will not finalized in study phase
Chlorine Demand sampling location at Leib agreed.	Chlorine System Automation Evaluation	19		X	General location for Chlorine Demand sample was agreed upon (in effluent channel) but exact location will be determined based upon CFD modeling results.	X		Recommendation will be based on CFD Model results.

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
TRC analyzer location to be in the existing sampling room.	Chlorine System Automation Evaluation	19	X			X		GLWA agreement during 5/12 Workshop. Typical for all location determinations - to be verified during design [BOD phase] as size requirements are finalized and appropriate virtual modeling is conducted
Redundant TRC analyzers will be provided	Chlorine System Automation Evaluation	19	X			X		GLWA agreement during 5/12 Workshop
Redundant TRC sample pumps	Chlorine System Automation Evaluation	19		X	Do not include redundant sample pumps for TRC analyzers, nor a shelf spare. Instead, utilize a lookup table with historic chlorine demand and decay data to select values to be utilized in the ICT algorithm if a sample pump is out.	X		From 5/24 meeting, would rather have on the shelf spare
Redundant influent sample pumps	Chlorine System Automation Evaluation	19		X		X		From 5/24 meeting, would rather have on the shelf spare

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
SHC (Hypo) proposed storage concentration (10.5% at Oakwood and 10% at Leib) as the basis of design.	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop
Oakwood - Do not install baffles in the RTB	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop
Oakwood - Replace existing SHC storage tanks with two new FRP tanks with a working storage volume of 15,000 gallons	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop
Oakwood - Replace existing feed system with recirculation loop w/ centrifugal pumps and flow control valves	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop
Leib - Replace existing SHC storage tanks with two new FRP tanks. Working storage volume to be 12,600 gallons	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop
Leib - Replace existing feed system with recirculation loop w/ centrifugal pumps and flow control valves	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Continue additional undisinfected, wet weather water quality sampling and analysis moving forward. Focus on undisinfected bacteria, along with TSS, turbidity, UVT, TOC and the other water quality parameters tested during CDM Smith sampling. Also perform blends of NWI/Oakwood to understand possible impacts to ICT value. Chlorine dose response testing should be performed periodically.	Chlorine System Alternatives	20	X			X		GLWA agreement during 5/12 Workshop. GLWA review comment GLWA Key Decisions Table review comment: CDM to recommend sampling program for GLWA. What is the timeline for this and when would it take place? [Response, sampling plan under development, intend begin shortly and be one year in duration.]
GLWA agreed with the recommendation to meter Oakwood basin influent flow using insertion type advanced Doppler flow meters on the storm pump discharge pipes, if can demonstrate that reliable for the proposed meter type in wet/dry application.	Basin Influent Flow Metering	21		X	Evaluate reliability with trial meter provided by ADS (Nivus meter)	X		5/24 meeting: Agreement subject to confirmation of reliability
GLWA agreed with the recommendation for backup flow estimate to be calculated within Ovation	Basin Influent Flow Metering	21		X		X		GLWA agreement during 4/19 Workshop

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
Storm wet well flushing: do not add header on "back side" of splitters; lower storm wet well flushing water header; remove sanitary flow trench covers; automate flushing sequence; flushing water quantity could increase as evaluated by Design Team.	Flushing Systems	22		X		X		GLWA agreement during 4/19 Workshop
Leib FD-1 - GLWA to confirm the inclusion of the screening inlet channels and the screening collection channel for the flushing system	Flushing Systems	22		X		X		GLWA agreement during 4/19 Workshop
OKW FD-2 - GLWA to confirm relocation of flushing valves. Also to confirm extension of flushing water header to the RTB sumps.	Flushing Systems	22		X		X		GLWA agreement during 4/19 Workshop
OKW FD-2 - GLWA to confirm the implementation of the sump conditioning pump and flushing water manifold in the RTB sumps.	Flushing Systems	22		X		X		GLWA agreement during 4/19 Workshop pending follow-up on action items

Description of Decision	Technical Memo		CDM Smith Team			GLWA		
	Title	T M	¹ Selected Alternative	² Key Decision	³ Recommended Path Forward	Agree	Disagree	Comments
OKW- GLWA prefers shoulder along the outer perimeter of the proposed road instead of curb and curb opening alternative, runoff to flow over the road and shoulder and drain into the bioswale	Site Civil Design	24		X	GLWA prefers this option to avoid plow damage to curb, deemed technically feasible	X		Discussed at 5/24 meeting
Leib - GLWA prefers that the Design Team utilizes drainage swales and the existing drainage system for the recommended alternative.	Site Civil Design	24		X	Determined to be technically feasible	X		GLWA preferred surface drainage and bioswale as expressed at 4/5 workshop
Leib - combining 3 parcels to avoid 2 separate drops	Site Civil Design	24		X	Additional meetings between GLWA, DTE and CDM Smith ongoing			Ongoing
Leib - the Alternative 2 with Fencing in the Vacated Alley	Site Civil Design	24	X			X		GLWA agreement during 4/5 Workshop

Notes:¹ Alternative selected by GLWA² If no alternative was selected by GLWA and Key Decisions were made this was used by the Engineer to make a recommendation³ Engineers Recommended Path Forward based on Key Decisions. Refer to GLWA Agree/Disagree column for confirmation of recommendation acceptance

Section 1

Introduction

1.1 Report Purpose

This Study and Conceptual Design Report documents the efforts the CDM Smith design team has undertaken during Task B of the Study Phase to define the improvements that will be further designed/developed during the Basis of Design Phase – Task C.

Major decisions that were made as a part of Task B are included in the final technical memorandums (TM's) in Section 2 of this report. This report is intentionally concise; the on-site investigation, project coordination, final conclusions and design criteria for progression undertaken as a part of this task are memorialized as within the TM's with the major decisions summarized within the executive summary.

1.2 Project Description

Professional services from the CDM Smith design team for Contract No. 2101475 CSO Facilities Improvements, has been focused on improving facility reliability, flexibility, operation, maintenance and safety to support planned increases in utilization/peak flow for the Oakwood and Leib CSO facilities upon completion of other projects that are being planned to divert flow from the Northwest Interceptor (NWI) to the Oakwood CSO Facility and to divert flow from the Meldrum sewer for treatment in the Leib SDF. In addition, engineering services included preparation and development of computational fluid dynamics (CFD) modeling for the Baby Creek SDF and the Connor Creek RTB CSO facilities.

1.3 Project Scope

Task B – Conceptual and Study Phase scope of work is summarized in Table 1-1, which lists the major tasks and the technical memoranda that discusses the investigation, results and recommendations of each task.

Table 1-1: Project Scope Major Tasks

Improvement No.	Description	Technical Memo No.
OKW-DIS-1	Chemical Feed Utilizing Manifold Pump Distribution and Centrifugal Pumps	17, 18, 19, 20
OKW-DIS-2	Install Flow-paced and TRC-paced Chemical Feed Control System	17, 18, 19, 20
OKW-DIS-3	Repair Hypochlorite Storage Tanks and Provide Side Access Manways	20
OKW-FD-2	Reservoir Flushing Valves Relocation and Sump Flushing	22
OKW-SITE-1	Site Improvements	11, 24
OKW-PUMP- 1A	Storm Pumps and Sanitary Pumps Operational Strategy	15
OKW-PUMP-1B	Rehabilitate Storm Pumps and Clean Wet Wells	2
OKW-PUMP-2	Eliminate Cast-in-Place Steps in Sanitary Wet Wells	3
OKW-I&C-1A	Improved Measurement of Basin Influent Flow	7, 21
OKW-I&C-1B	Process Cameras	7
OKW-SCR-2	Oakwood Screw Conveyor & Grinder System	4
LEIB-DIS-1	Chemical Feed utilizing Manifold Pump Distribution and Centrifugal Pumps	17, 18, 19, 20
LEIB-DIS-2	Provide Flow-paced and TRC-paced Chemical Feed Control System	17, 18, 19, 20
LEIB-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	17, 18, 19, 20
LEIB-FD-1	Screening Chamber Flushing System	22
LEIB-HVAC-1	HVAC Improvements	8, 9
LEIB-SCR-1	Screening Improvements and Pilot Screen	5
LEIB-SITE-1	Site Improvements and Alternate Access	11, 24
LEIB-ELEC-1	Electrical Improvements	6
LEIB-I&C-1A	I&C Improvements	7
LEIB-I&C-1B	Process Cameras	7
BC-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	13
CON-DIS-3	Model Disinfection Performance and Replace/Utilize Half of the In-Kind Mixers	14

Section 2

Final Technical Memoranda

2.1 Site Civil, TM-11 & TM-24

Oakwood CSO Retention Treatment Basin (RTB) and Pump Station

- Replace gravel road around CSO basins with concrete pavement
- Improve poor surface drainage around CSO basins
- Expand swales around CSO basins
- Replace damaged concrete pavement and sidewalks
- Remove vegetation from surge basin area

Leib CSO Screening and Disinfection Facility (SDF)

- Provide new access roadway off Meldrum St.
- Add fencing for second access road to site
- Drainage modifications to accommodate access roadway
- Add bollards for protection as needed along access roadway
- Provide motorized access rolling gate

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Mark Schobert, CDM Smith
Atul Kajale, CDM Smith
Spalding DeDecker (Sub-Consultant)
SOMAT (Sub-Consultant)*

Date: June 1, 2023

*Subject: TM-11 Survey and Site Constraints
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The purpose of this technical memo (TM) is to characterize above ground and below ground existing conditions to support the design of the site improvements described as OKW-SITE-1, and LEIB-SITE-1.

Topographic surveys and geotechnical investigations of the Oakwood (OKW) and Leib sites were performed in the fall of 2022. The Design Team conducted the Topographic Surveys and Geotechnical Field Investigations, and prepared the Draft Geotechnical Investigation Reports.

The existing conditions base mapping, and geotechnical reports and findings for both sites are included as appendix items to this TM. Also included in the appendix are relevant as-built drawings and the MISS DIG utility files which were supplied to the surveyor by third-party utilities near the subject project sites.

The information in this technical memorandum is utilized for concept design in TM – 24 – Site/Civil Design

1.0 Introduction and Purpose

The purpose of this TM is to support the design of the site improvements described as OKW-SITE-1, and LEIB-SITE-1 in the Engineering Services Agreement for the Combined Sewer Overflow (CSO) Facilities Improvements Project. These improvements are also referenced in the CS-299 CSO Facility Needs Assessment Report dated April 9, 2021 (CS-299 Report). The improvements are intended to improve facility reliability, flexibility, operation, maintenance, and safety to support planned increases in utilization for the Oakwood and Leib CSO facilities upon completion of other projects that are being planned for implementation. The Oakwood Facility is located at 12220

Pleasant Street, Detroit, MI 48217. The Leib Facility is located at 2198 Mt Elliot Street Detroit Michigan.

OKW-SITE-1 consists of paving an existing gravel drive that goes around the CSO basin, fixing drainage issues and damaged concrete around the CSO basin area, sealing the existing concrete driveway areas, and removing the overgrowth of vegetation in the surge basin area.

LEIB-SITE-1 consists of confirming the size, configuration, and geometry of a new access drive from Meldrum St. and associated changes to the Leib parking lot, parking lot striping, protection of the transformer with bollards, fencing, motorized vehicle gate, security badge access, and necessary electrical needed to facilitate the improvements. Three parcels in which the driveway is intended to cross are owned by Detroit Water and Sewerage Department (DWSD). The alley in between the existing Leib Facility parcel and these three parcels has been vacated. Electrical and telecommunications providers have utilities in the influence of the proposed driveway.

Topographic surveys of the Oakwood and Leib sites, as well as adjoining right-of-ways and parcels were performed in fall of 2022 utilizing aerial imagery and conventional ground surveying methods. Digital terrain models were computed, and contours developed at 1-foot intervals. Facility records and third-party utility information obtained from MISS DIG requests were obtained and checked against the survey field information to develop site base maps of existing conditions to be used for conceptual design. Underground utilities are shown based upon a combination of record information along with actual field measurements for above-ground manifestations of underground utilities. Mapping in both pdf and CAD formats is provided and a set of base map drawings have been produced for each site using Civil 3D.

Two Draft Geotechnical Reports have been prepared, one for each site. The geotechnical reports are attached in Appendix B of this report. At the Oakwood Site, the field exploration program consisted of six hand-auger probes which were extended to depths approximately 4 to 6 feet below existing grades to support the design of new pavement and a potential bioswale feature. The proposed pavement section is 9-inch-thick reinforced concrete over a minimum 8-inch-thick aggregate MDOT 21AA base with HS-20 loading. Geotechnical recommendations for the proposed pavement section and proposed bio-swale are provided in the geotechnical report. At the Leib Site, the field exploration program consisted of two soil borings which extended to 10 feet below existing grades to support the design of new 9-inch-thick reinforced concrete over a minimum 8-inch-thick aggregate MDOT 21AA base with HS-20 loading. Geotechnical recommendations for the proposed pavement section are provided in the geotechnical report.

2.0 Existing Systems Description and Conditions

Figures 2-1 and **2-2** show aerial photographs of the Oakwood and Leib Sites respectively taken in fall of 2022. Mt Elliot Street in front of the Leib Facility has been recently paved and striped.

Figure 2-1
Fall 2022 Aerial Image of Oakwood Site, 12220 Pleasant Street, Detroit

Figure 2-2
Fall 2022 Aerial Image of Leib Site, 2198 Mt Elliot Street, Detroit

2.1 Oakwood Site – Existing Conditions

A site visit was conducted November 22, 2022 at the Oakwood Site. Pictures were taken of existing conditions around the CSO Basin. **Figures 2-3, 2-4, and 2-5** show photos taken along the existing gravel roadway on the west, north, and east side of the Oakwood CSO Basin. The gravel roadway is uneven, has many areas of standing water and is poorly drained.

Figure 2-3
Site Photos – West Side of Oakwood CSO Basin

Figure 2-4
Site Photos – North Side of Oakwood CSO Basin

Figure 2-5
Site Photos – East Side of Oakwood CSO Basin

Two storm manholes are presumed to be buried beneath the gravel roadway and could not be located with a metal detector. Several large concrete vaults lie within or adjacent to the gravel roadway on the west side of the CSO Basin and will need to be integrated into the paving plan. These chambers are the Sanitary Surge Relief Chamber, the Drain to Northwest Interceptor (NWI) Meter Vault and the Drain to NWI Valve Vault. **Figure 2-6** shows the location of these features. **Figure 2-7** shows the electrical and instrumentation conduits which are below the gravel roadway on the western side of the Oakwood CSO Basin. **Figure 2-8** shows pictures during construction of the existing underground duct bank which was constructed as part of the facility in 2012.

Figure 2-6
Existing Site Conditions Around Oakwood CSO Basin

Page 8

The Oakwood CSO Facility Drain Valve Improvements Project (CON-254) Existing Electrical As-Built drawings dated 10/15/19, indicate a new duct bank was installed over an existing duct bank which runs beneath the existing gravel roadway. (**Figure 2-9**) The new duct bank is approximately 30-inches below grade and runs from existing I&C manholes 201 and 202 to the existing Drain Valve Vault located at the northwest corner of the facility. The existing duct bank will need to be considered as drainage options are evaluated in TM-24 Civil/Site Design.

Figure 2-9
CON254 –New Duct bank 30 inches Below Grade Installed Over Existing Duct Bank

Table 2-1 shows third-party utility information obtained from MISS DIG requests for the Oakwood site.

Table 2-1 Oakwood Existing Site Utilities

Utility Provider	Contact Number	MISS DIG RESULTS	Date
AT&T TELEPHONE	(231) 409-7939	RECEIVED	10/26/2022

2.2 Leib Site – Existing Conditions

A site visit was conducted November 22, 2022 at the Leib Site. Pictures were taken of existing conditions around the CSO Basin. **Figure 2-10** shows notable existing features of the site. These features include:

- 1) An existing DTE Transformer and underground service from existing DTE Pole. The existing DTE Transformer is located in the parking lot. A buried electrical service lead runs from the transformer to a nearby DTE Pole. The underground DTE service lead crosses a vacated alley which will be paved over to provide a new service entrance driveway to the Leib CSO facility. The existing DTE Electric Pole carries the existing AT&T wire which will need to be raised to provide clearance for service trucks using the new service drive to the facility.
- 2) Existing AT&T pole. The existing AT&T pole is located in the vacated alley.
- 3) Existing rolling gate and actuator at the entrance to the CSO Facility off of Mt Elliot.

Figure 2-10
Existing Site Conditions Photos at the Leib Site

Table 2-2 shows third-party utility information obtained from MISS DIG requests for the Leib site.

RE: Report on Geotechnical Investigation
Great Lakes Water Authority (GLWA)
Design Services for Combined Sewer Outfall (CSO) Improvements Project
GLWA Oakwood CSO Facility - Contract Number 2101475
Detroit, Michigan

Dear Mr. Khraizat:

We have completed the Report on Geotechnical Investigation for the GLWA Oakwood CSO Facility Project in the City of Detroit, Michigan. This report presents the results of our observations and results of the geotechnical.

The soil samples collected during our field investigation will be retained in our laboratory for 90 days from the date of the final report, at which time these samples will be discarded unless otherwise directed by you.

It was a pleasure working with you on this project. If you have any questions regarding this report, please do not hesitate to contact us 313-963-2721.

Sincerely,
Somat Engineering, Inc.

**REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

REPORT SUMMARY

A general summary of the report conclusions is provided below:

1. The field exploration program consisted of performing a total of 6 hand auger probes for the GLWA Oakwood CSO Facility Project in Detroit, Michigan. The auger probes extended to depths ranging between 5 and 6 feet below existing grades.
2. Generalized soil profile: fill soils were encountered in 4 of the 6 auger probes and extended to depths ranging between 2 and 5.5 feet below existing grades. The fill soils generally consisted of roadway gravel and granular soils. Native soils consisting of lean clay or sandy lean clay were encountered below the fill or below the topsoil and extended to the exploration depths of the probes. The consistency of the native clays was stiff to very stiff and the moisture content ranged between 15 and 45%.
3. Groundwater was not encountered during or upon completion of augering in any of the probes. Based on the change from brown to gray in the cohesive soils of SB-04 and 06, the long-term groundwater table is estimated to be situated at about 3.3 to 4 feet (EL. 95 to 99 feet±) below existing grades. Perched groundwater trapped in the granular fill soils within close proximity of any excavations should also be expected.
4. The gravel service road is planned to be replaced with new reinforced concrete pavement that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. The current pavement design calls for a total length of about 1,000 lineal feet and a width of 16 feet in addition to 2-foot-wide shoulder on the outer side. The shoulder will be gravel and will not be paved. The pavement will be widened at the turns to facilitate the turning of WB-50 trucks. The proposed pavement section will be Portland cement concrete (PCC) designed to support HS-20 loading.
5. Based on our probe investigation, the existing gravel road consisted of 10 to 18 inches of crushed aggregates mixed with silty sand over granular fill soils. The fines content of the existing gravel road material ranged between 11 and 25% which is higher than the allowable limit of fines content of MDOT 21AA aggregate. The excessive fines in this material would reduce its permeability and increase its susceptibility to detrimental frost action. Therefore, it is NOT suitable for re-use as base course below the new pavement. As such, we recommend removal of a portion of the existing gravel and replacing with new, clean, and compacted aggregate base material similar in gradation to MDOT 21AA. The remaining existing crushed aggregate (if any) may be left below the new base course.

**REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

6. Based on our analysis, the following proposed pavement section design should be adequate to support the required traffic loading for the access drive. This pavement section should be uniform across the mainline and the widened turns.
- 9 inches of Portland cement concrete, over
 - 8 inches of new aggregate base course similar in gradation to MDOT 21AA, over
 - (only where required) Triaxial geogrid such as Tensar NX750 or another engineer approved geogrid equivalent, over
 - The compacted existing subgrade soils consisting of the remaining road gravel and granular fill soils.

The geogrid should be placed at the widened paved turns since the bearing soils at these areas have not been pre-consolidated in the past. To avoid differential settlement and pavement cracking at these widened turns, we recommend the geogrid to be placed immediately below the new 21AA base material and should span laterally from edge of pavement to edge of pavement with a minimum two feet extension beyond the outer (widened) edge. Longitudinally along the road, the geogrid should extend a minimum of 3 feet on either end of the widened section.

The geogrid installed as described above may also be used to bridge over the organic pocket encountered in Boring SB-03 at a depth of 3 feet below grade. This is an alternative to undercutting these organics to their full vertical extent and replacing with engineered fill.

Compact the existing subgrade with a vibratory roller or plate compactor until subsequent passes result in no significant downward displacement. The subgrade and the new base material should be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D1557 (Modified Proctor).

7. A total of 3 auger probes were performed within the existing bioswale located on the west side of the basin. The general soil profile consisted of topsoil over granular fill soils over native clays. The layer of the granular fill soils consisted of clayey sand and ranged in thickness between 4 and 18 inches. These fill soils had 43% of fines (silt and clay) which is considered elevated and will not promote positive drainage. Based on the in-situ falling head permeability tests performed at a depth of 4 to 6 feet below existing grades, the mean hydraulic conductivity of the existing native clay soils ranged between 0.007 and 0.025 inch/hour which is considered almost impermeable.

For the proposed bioswale, we recommend undercutting the existing fill and some of the native clay soils and replacing with drainable engineered fill with gradation in accordance with the GSI design specifications. The width, length, and depth of the proposed bioswale will be designed by others to accommodate the anticipated volume surface water surface runoff during the wet seasons, and taking into consideration the anticipated long-term groundwater table at the site.

**REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA OAKWOOD CSO FACILITY
DETROIT, MICHIGAN**

1.0 INTRODUCTION

1.1 GENERAL

Upon authorization from CDM Smith, Somat Engineering, Inc. (Somat) has completed the geotechnical investigation for the development of the Great Lakes Water Authority (GLWA) Design Services for Combined Sewer Outfall (CSO) Improvements Project at the Oakwood CSO Facility in the City of Detroit, Wayne County, Michigan.

Somat was retained by CDM Smith to perform a pre-design geotechnical investigation for the referenced project within the project limits. The geotechnical investigation was performed in general accordance with Somat Proposal No. P210314B dated January 12, 2022. The results of the investigation will be used to support the design of the project and development of construction specifications.

1.2 PROJECT INFORMATION

The overall project includes design services required to implement a series of improvements at the Oakwood CSO Retention Treatment Basin (RTB) and storm/sanitary pumping station located at 12220 Pleasant Street, Detroit, Michigan. The site improvements include constructing a new access service drive that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin and expanding the existing bioswale on the west side of the basin to improve drainage conditions.

The following sections of this report provide a description of our field investigation, the results of the field and laboratory tests, the logs of auger probes, our interpretation of subsoil and groundwater conditions, recommendations related to the proposed construction.

2.0 SUBSURFACE INVESTIGATION

2.1 FIELD EXPLORATION

The field exploration program consisted of performing a total of six (6) hand auger probes, designated SB-01 through SB-06. Borings SB-01, 02, and 03 were performed along the existing gravel access road and extended to a depth ranging between 5 and 5.5 feet below existing grades. In-situ Dynamic Cone Penetrometer (DCP) tests were performed at each of these probes to assess the strength of the subgrade soils and support the pavement section design of the access road.

Hand auger probes SB-04, 05, and 06 were performed along the existing bioswale that is located on the west side of the basin. These probes extended to depths ranging between 4 and 6 feet below existing grades. In-situ infiltration tests were performed near each of these probes at depths ranging between 4 and 6 feet below existing grades.

Soil boring coordinates and the ground surface elevations (included in the soil boring logs) were provided by the Project Surveyor using City of Detroit Datum. A schematic of the approximate soil boring locations and the corresponding infiltration test locations can be found in Appendix A. The Logs of Test Borings are included in Appendix B.

2.1.1 Drilling Operations

The drilling operations were performed on December 1 and December 2, 2022. The hand auger probes were performed using a 3-inch hand auger bucket. Upon completion, all boreholes were backfilled with soil cuttings and the site was restored to the best of our ability.

2.1.2 Geotechnical Sampling

Bulk soil samples were collected from each hand auger probe at every apparent stratum change. The samples were sealed in plastic zip lock bags in the field to protect the soil and maintain the soil's natural moisture content. All samples were identified with unique information on hand auger number, sample number, and sample depth. The samples were transported to Somat's laboratory in Romulus, Michigan.

All soil samples for the geotechnical investigation were transported to Somat's laboratory for further analysis and testing and will be retained in our laboratory for a period of 90 days after the date of the final report, after which they will be discarded unless we are notified otherwise.

2.1.3 In-Situ Dynamic Cone Penetrometer (DCP) Tests

A dual-mass Dynamic Cone Penetrometer (DCP) test was performed in general accordance with ASTM D6951 at probes SB-01, 02, and 03. The test was performed starting at the surface material, and extended to depths of about 4 feet below existing grade, approximately. The DCP test is utilized to estimate the California Bearing Ratio (CBR) values from 0.1 to 100. A CBR value is an index commonly used in pavement design, indicative of base and subgrade support characteristics for granular soils. The test procedure involves dropping a 17.6-pound hammer from a distance of 22.6 inches onto an anvil/coupler assembly that drives the graduated drive rod with a disposable cone or tip. The cone has a 60° angle with a maximum diameter of 0.79 inches. The rate of cone penetration per blow is measured at selected penetration or hammer drop intervals. The analysis was performed based on relationships developed by USACE to estimate the California Bearing Ratio (CBR) value from the results of the DCP test. The correlated CBR values ranged between 10 and 100 (an outlier CBR of 4.8 was eliminated). The DCP test results and correlated CBR values are presented in Appendix C.

2.1.4 Groundwater Level Observation Procedures

Whenever possible, groundwater level observations were made during the augering operations and are shown on the individual Logs of Auger Probes. During augering, the depth at which free water was observed, where soil cuttings became saturated or where saturated samples were collected, was indicated as the groundwater level during drilling. In granular, pervious soils, the indicated water levels are considered relatively reliable when hand auger probes are used. However, in cohesive soils, groundwater observations are not necessarily indicative of the static water table due to the low permeability rates of the soils, and due to the sealing off of natural paths of groundwater flow during augering operations.

It should be noted that seasonal variations and recent precipitation may influence the level of the groundwater table significantly. Groundwater observation wells are generally used if precise groundwater table information is needed, however, the installation of groundwater monitoring wells was not included in the scope of the investigation. Therefore, the discussion and recommendations provided within the report are based on our knowledge of the soil and groundwater conditions in this area, which should provide for a reasonable approximation of the groundwater level.

2.1.5 In-Situ Falling Head Permeability Test

The falling head in-situ permeability testing was performed in accordance to the Stormwater Management Design Manual of the City of Detroit Water and Sewerage Department (2018 which is adapted from the Philadelphia Water Stormwater Management Guidance Manual (Philadelphia Water, 2015). The permeability tests consisted of the following steps:

1. Advance a borehole to the required depth of the proposed infiltration interface depth of 4 to 6 feet using a 6-inch hand auger bucket. The augured hole diameter is at least two inches larger than the outer diameter of the inner casing. The inner casing will consist of a PVC pipe with minimum inner diameter of four inches.
2. Push the inner casing within the augured hole to the infiltration interface and firmly set into the bottom of the borehole. Measure the depth from the top of casing to the bottom of the hole to the nearest 0.1 feet.
3. Place two inches of fine gravel or coarse sand in the bottom of the borehole to prevent scour during filling of the casing. Place gravel or sand uniformly to obtain an even depth within the hole. Re-measure the depth from the top of casing to the gravel or sand surface to the nearest 0.1 feet.
4. Presoak test holes immediately prior to testing to simulate saturated conditions. Fill casing with water at a very low rate so as not to disturb the bottom sediments. Place water to a depth of at least six inches above the bottom and readjust every 30 minutes for one hour. The drop in the water level during the last 30 minutes of the presoaking period to be applied to the following standard to determine the time interval between readings:
 - a. If water level drop is two inches or more, use ten-minute measurement intervals.
 - b. If water level drop is less than two inches, use 30-minute measurement intervals.
5. After the presoaking, the water level is measured using an approved method per the ASTM standard, where the water level remains at least 12 inches above the bottom of the bottom of the hole. All water added was recorded as a volume along with the time of addition.

6. Measurements of water level were made from the top of casing and continued at the interval determined until a minimum of eight readings are completed or until a stabilized rate of drop was obtained, whichever occurred first. A stabilized rate of drop means a difference of about 0.25 inch or less of a drop between the highest and lowest readings for four consecutive readings.
7. Calculate the infiltration rate as described in ASTM D6391.

The results of the permeability tests and the graphic presentation of the calculated mean hydraulic conductivity, K_1 , versus the elapsed time at each test location are discussed in Section 3.3 and presented in Appendix D.

2.2 GEOTECHNICAL LABORATORY TESTING

All soil samples were classified in accordance with the Unified Soil Classification System (USCS). Cohesive soil samples were subjected to laboratory tests consisting of moisture content determinations, hand penetrometer tests, grain size analysis, and Atterberg Limits tests. Loss-on-ignition (LOI) tests were performed on any samples that appear to contain significant organic content.

The results of the soil classifications and the laboratory tests are included on the respective Logs of Auger Probes in Appendix B and/or tabulated or presented graphically in Appendix E. All laboratory tests were performed in accordance with their applicable ASTM procedures. A general description of each test method is presented in Appendix E, immediately following the result sheets.

2.3 LIMITATIONS

The scope of our services was strictly geotechnical and did not include environmental investigation. Our scope of services did not include investigation for the presence or absence of wetlands or hazardous or toxic materials in the soil, surface water, groundwater, or air, on, below or around this site.

Somat has made no observations or recommendations with regard to the presence or absence of mold or other biological contaminants (such as spores, fungi, bacteria, viruses, and the byproducts

of such organisms), now or in the future, on this site or within or on any structures to be constructed on this site. Any consideration with regard to the presence of mold, or the possibility of mold growth in or on the structure to be constructed on this site are not within our scope of services on this project.

Some soils have been identified on the Logs of Test Borings as “fill” or “possible fill” if a soil deposit is suspected to have been placed by human activity, versus having been deposited by natural means. These designations were based on our professional engineering judgment considering factors such as our visual classification, the presence of foreign materials (i.e., bricks, concrete, plastic, etc.), and/or site topography, among many other possibilities. As such, the “fill” or “possible fill” descriptions should be considered as secondary information to the standardized soil classification. Due to the large variation of types of fill, methods of fill placement, potential changes of historical use of the site, and soil sample size, it is difficult to discern whether the subject soil sample is native to this site, or fill material based on visual classification alone. As such, the designation of “fill” may not be reliable and hence should be considered as informational only. Conversely, where a soil is not designated as “fill” on the boring logs, it does not necessarily mean it is not a fill soil, only that there were no apparent observations indicating a fill material. Therefore, we cannot guarantee that our description of “fill” soils is accurate, or that we have identified all types of fill material encountered with our sampling on the site.

3.0 SUBSURFACE CONDITIONS

3.1 SOIL CONDITIONS

Soil conditions encountered at the boring locations have been evaluated and presented in the form of logs of auger probes. The logs of auger probes include approximate soil stratification with detailed soil descriptions and selected physical properties for each stratum encountered in the auger probes. In addition to the observed subsoil stratigraphy, the auger logs present information relating to sample data, groundwater level conditions observed in the probing, personnel involved, and other pertinent data. For information, and to aid in understanding the data as presented on the auger

logs, General Notes defining nomenclature used in soil descriptions are presented immediately following the Logs of Test Borings. It should be noted that the Logs of Test Borings included with this report have been prepared on the basis of laboratory classifications and testing as well as field logs of the soils encountered.

A generalized description of the soils and pavement encountered in the six (6) auger probes beginning at the existing ground surface and proceeding downward, is provided below:

Stratum 1: Surface Material:

- **Topsoil:** Clayey topsoil was encountered at the surface of SB-04, SB-05, and SB-06 and had a thickness of 6 inches.
- **Roadway Materials:** Fill soils consisting of a mixture of crushed aggregate and silty sand were encountered at the surface of SB-01, SB-02, and SB-03. These fill soils extended to depths ranging between 0.8 and 1.5 feet below existing grades and had fines content ranging between 11 and 25% (silt and clay).

Stratum 2: Fill Soils:

- **Granular Fill:** Silty sand and clayey sand fill soils with varying amounts of silt and gravel were encountered below the topsoil in SB-04 and 05, and below the roadway gravel in SB-01, 02, 03. The fill soils extended to depths ranging between 2 and 5.5 feet below existing grades. The granular fill extended to the termination depths of auger probes SB-01 and SB-03. The fines content ranged between 11 and 43%. Organic pocket was encountered in the granular fill soils in SB-03 at a depth of about 3 feet below existing grades. Based on the Loss-On-Ignition (LOI) test the organic content was 7.2%.

Stratum 3: Native Cohesive Soils

- Native brown and gray lean clay or sandy lean clay soils were encountered generally below the fill soils in SB-02 and SB-05, and below the topsoil in SB-06 and extended to the explored depths of the auger probes at 4 to 6 feet below existing grades. The consistency of the clay was stiff to very stiff. The moisture content of the native clays ranged between 15 and 45%. Based on the Atterberg limits test result on the clay sample obtained from a depth of 5 feet at probe SB-01 the liquid limit was 38% and the plasticity Index (PI) was 18%. Graphical presentation of the Atterberg Limits results plotted on the Casagrande chart shows that the clay is classified as lean clay (CL). The chart is presented in Appendix E.

The Logs of Auger Probes are presented in Appendix B and the Hand Auger Probe Location Diagram is presented in Appendix A. It is emphasized that the stratification lines shown on the Logs of Test Borings are approximate indications of change from one soil type to another at the locations of the boreholes. The actual transition from one stratum to the next may be gradual and may vary within the area represented by the test boring.

3.2 GROUNDWATER LEVEL OBSERVATIONS

Groundwater was not encountered during drilling or upon completion of any of the hand auger probes. A lack of groundwater in some of the auger holes, does not necessarily mean there is no groundwater in this area, due to the sealing off of natural flow paths during the drilling process. Oftentimes, a change in color from brown to gray in cohesive soils is a good indication of the long-term groundwater level (indicating oxidation). Based on the change from brown to gray in the cohesive soils of SB-04 and SB-06, the long-term groundwater table is estimated to be situated at about 3.3 to 4 feet below existing grades (EL. 95 to 99 feet±).

Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected.

It should be noted that the elevation of the long-term groundwater table is likely to vary throughout the year depending on the amount of precipitation, runoff, evaporation, and percolation in the area, as well as on the water level in any surface water bodies in the vicinity affecting the groundwater flow pattern.

3.3 IN-SITU FALLING HEAD PERMEABILITY TEST RESULTS

The in-situ falling head permeability testing was performed in accordance to the Stormwater Management Design Manual of the City of Detroit Water and Sewerage Department (2018 which is adapted from the Philadelphia Water Stormwater Management Guidance Manual (Philadelphia Water, 2015)).

Per the request of CDM Smith, the infiltration tests were performed at about 4 to 6 feet below existing grades in the native soils. The mean hydraulic conductivity, K_1 , is defined as the average rate of water movement through a saturated soil mass, as tested for the in-situ permeability testing using the falling water level method. The mean hydraulic conductivity was calculated based on the equation adopted from ASTM D6391-11.

The equation is as follows:

$$K_1 = R_T G_1 \frac{\ln\left(\frac{Z_1}{Z_2}\right)}{(t_2 - t_1)}$$

Where:

K_1 is the mean hydraulic conductivity in inch/hour and in cm/sec

G_1 is the test setup parameter

R_T is the temperature coefficient

t_1 and t_2 are the time interval in seconds

Z_1 and Z_2 are the head measurements in cm, measured from the bottom of the borehole to the water level.

The results of the hydraulic conductivity, in equivalent inches per hour, at each testing location were then compared to soil textures of the U.S. Department of Agriculture (USDA) textural triangle presented in Table 3.3-1 to identify the general soil texture and the corresponding hydrologic soil grouping. The following table is an excerpt of the USDA Classification Table:

Table 3.3-1 - Summary Table of Hydraulic Soil properties Classified by Soil Texture

Texture class	Minimum Infiltration Rate (Hydraulic Conductivity) (Inch/hour)	Hydrologic Soil Grouping
Sand	8.27	A
Loamy Sand	2.41	A
Sandy Loam	1.02	A
Loam	0.52	B
Silt Loam	0.27	B
Sandy Clay Loam	0.17	C
Clay Loam	0.09	D
Silty Clay Loam	0.06	D
Sandy Clay	0.05	D
Silty Clay	0.04	D
Clay	0.02	D

The following Table 3.3-2 summarizes the mean hydraulic conductivity measured at each borehole and interpretation for the corresponding soil texture and hydrologic group based on the referenced USDA soil group. The results of the in-situ falling head tests and the graphic presentation of the mean hydraulic conductivity (in cm/sec) versus the elapsed time (in seconds) at each test location are presented in Appendix D.

Table 3.3-2 Summary Table of the In-Situ Falling Head Permeability Tests Results

Hand Auger Probe ID	Mean Hydraulic Conductivity, K_1 (cm/sec)	Mean Hydraulic Conductivity, K_1 (inch/hour)	General Soil Texture and the Corresponding Hydrologic Soil Grouping*	
			Texture Class	Hydrologic Soil Grouping
SB-04	7.062E-06	0.01	Clay	D
SB-05	1.736E-05	0.025	Clay	D
SB-06	5.181E-06	0.007	Clay	D

*Based on soil textures of the U.S. Department of Agriculture (USDA) Textural Triangle

Based on the in-situ falling head permeability tests performed at a depth of 4 to 6 feet below existing grades, the mean hydraulic conductivity of these soils ranged between 0.007 and 0.025 inch/hour (1.7E-05 – 5.2E-06 cm/sec).

4.0 GEOTECHNICAL RECOMMENDATIONS

4.1 PROPOSED ACCESS SERVICE DRIVE

The project includes the construction of a new paved access service drive around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. The current design calls for a total length of about 1,000 lineal feet and a width of 16 feet. There will be a gravel shoulder on the outside edge of this access drive. We understand that the shoulder will be gravel and will not be paved. The proposed pavement section will be Portland cement concrete over aggregate base course that is in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading. Some added width of the pavement is anticipated at the curvatures to increase the radius and facilitate the turning of large vehicles such as WB-50 trucks.

4.1.1 Existing Subgrade Conditions

Based on the hand auger probes, the existing access road consists of 10 to 18 inches of a mixture of gravel and silty sand (road gravel) over granular fill soils. Based on the laboratory grain size analysis performed on the surface gravel layer, the fines content ranged between 11 and 25% which is considered excessive. Also, the gradation does not conform with the gradation of MDOT 21AA because the percent finer by weight was exceeded for the ½ inch, #8, and #200 sieves. As such, we do NOT recommend re-using the existing road gravel material as a base course below the new pavement because the excessive fines may reduce the ability of the material to effectively allow drainage below the pavement and may pose a risk of detrimental frost action.

The existing granular fill soils below the gravel layer consisted of poorly graded sand with silt and silty sand which extended to a depth of 4.5 to 5.5 feet below existing grades. Native stiff clay was encountered at a depth of 4.5 feet in boring SB-02 and extended to the explored depth of 5 feet.

A pocket of organics was encountered in the granular fill soils at a depth of about 3 feet at the location of probe SB-03. Loss-On-Ignition (LOI) test performed on that soil sample showed an organic content of 7.2% which is considered excessive. In general, we would recommend undercutting this localized area to remove the organics to its full depth and replacing with clean

granular engineered fill. There should be no concerns of creating a bathtub due to the undercut and backfill because the procedure is performed within the existing granular fill soils and not in the native cohesive soils.

Alternatively, using the geogrid as recommended in Section 4.1.4.2 should help bridge over such similar organic pockets and minimize the settlement potential under the new pavement due to the decomposition of the organic material.

4.1.2 Subgrade Preparation and Groundwater Control Recommendations

Once a rough subgrade has been achieved, the exposed pavement subgrade along the entire section of access service drive to be constructed should be visually checked for the presence of debris, organic matter, and other unsuitable material.

If unsuitable or highly organic subgrade soils (organic contents greater than 4%) are encountered during construction, the material should be assessed by the on-site geotechnical engineer to determine the depth and extent of the material and whether it should be fully undercut.

All of the pavement subgrade areas should be thoroughly proof rolled before placement of the new base course and pavement. The purpose of the proof rolling is to locate overly loose or soft areas as well as to uniformly compact the subgrade surface. In granular soils, proof rolling should be performed with a heavy (minimum 30 ton) self-propelled vibratory roller. Loose or soft areas revealed during compaction or during the proof rolling should either be suitably compacted and aerated if necessary. Any areas that exhibit excessive pumping or yielding should be stabilized, scarified, and re-compacted, if weather conditions permit, or by the removal of the yielding soils and their replacement with engineered fill.

The subgrade and base material will need to be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D1557 (Modified Proctor). It may

be necessary in some areas to undercut unsuitable soils and replace them with a stabilization layer of engineered fill.

Based on the change from brown to gray in the cohesive soils encountered at SB-04 and SB-06, the long-term groundwater table is estimated to be situated at a depth of about 3.3 to 4 feet below existing grades (EL. 95 to 99 feet±). Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected. We do not expect the excavations required to construct the access service drive would extend below the estimated long-term groundwater. As such, we believe the groundwater should be adequately controlled using standard sump pits and pumping methods.

4.1.3 Drainage Considerations

The effects of frost heave are anticipated to be more significant in areas where water is not allowed to drain freely either due to subsoil conditions, site grades, or other factors. We recommend including a new drainage system within the new base course to drain water away from the pavement. The pavement and subgrade will need to be positively graded towards these drainage features or away from the center of the roadway to allow for gravity flow of groundwater. As we understand, the storm runoff from the site will be collected and conveyed to the storm junction chamber upstream of the Oakwood CSO.

For all new pavements, final pavement elevations should be designed to provide positive surface drainage. The minimum surface slope of 2 percent is recommended. The pavement surface should be smooth, free of roller marks or depressions, and should not contain any irregularities which would pond or impede water flow

4.1.4 Pavement Design Recommendations

4.1.4.1 Subgrade Design Values

We anticipate the subgrade soils for the proposed pavement construction will consist of existing fill soils. The recommended subgrade resilient modulus (M_R) and vertical subgrade reaction (K_v) provided below assumes the soil conditions encountered in the auger probes are representative of the soil conditions within the proposed pavement construction areas. This also assumes the recommended earthwork operations will have been incorporated into the project specifications and that the subgrade soils will have been compacted. If during construction, the subgrade is found to vary from the expected soil conditions, we should be contacted so we may re-evaluate our soil design parameters.

For Portland cement concrete pavement design, based on our experience with similar soil conditions and the results of the in-situ DCP tests, we recommend the following coefficients of subgrade reaction (K_v), subgrade resilient moduli (M_R), and CBR's be used as representation for the conditions of the soils at the new base course and subgrade levels compacted to project specifications.

Table 4.1.4.1 Recommended Pavement Subgrade Design Parameters

Soil Type	Coefficient of Vertical Subgrade Reaction, (K_v)	Subgrade Resilient Moduli (M_R)	CBR
Existing Granular Fill subgrade compacted in place	175 pci	15,000 psi	10 (lowest CBR value shown in the in-situ DCP tests)
Existing Native Clay Soils	85 pci	6,000 psi	4
New Engineered Sand Fill (MDOT Class II)	235 pci	22,500 psi	15
New Engineered Aggregate Base (MDOT 21AA)	340 pci	37,500 psi	25

Other factors should also be considered in the final pavement design, in addition to the subgrade modulus values. These factors may include, but are not limited to, adequate subgrade preparation, adequate placement of engineered fill and pavement layers, and surface and subsurface drainage.

4.1.4.2 Pavement Section Design Recommendations

The pavement will be designed to support HS-20 loading. We performed pavement analysis utilizing the AASHTO 1993 Guide for Design of Pavement Structures and the associated design charts and nomographs. The following list summarizes our input parameters and assumptions based on AASHTO guidelines and our observations:

Pavement Design Life	20 years (7 days per week)
Loading	HS-20 (8,000 lb/ front axle and two 32,000 lb/ rear axles (Given)
Load Equivalent Factor (LEF)	2.985 (calculated based on HS-20 loading using AASHTO LEF tables for terminal serviceability of 2.5)
Maximum Average Daily Traffic (ADT)	200 vehicles per day with HS-20 loading criteria (Back calculated)
Maximum Design ESAL's:	4,200,000 ESAL (Back calculated)
Percent Trucks:	100 %
Reliability:	90 % (Arterial road)
Standard Deviation:	0.35 (Rigid pavement)
Drainage Coefficient:	1.0
Initial Serviceability:	4.5 (Rigid pavement)
Terminal Serviceability:	2.5 (Major collectors)
Growth Rate	3%
Load Transfer Coefficient	2.7 (Dowel and mesh)
Concrete Elastic Modulus	6,000,000 psi (Assumed)
Effective Modulus of Subgrade Reaction of new base course (MDOT 21AA)	340 pci (CBR =25)
Mean Concrete Modulus of Rapture	650 psi

Based on our analysis, the following proposed pavement section design should be adequate to support the proposed traffic loading for the access service drive. This pavement section should be uniform across the mainline and the widened turns.

- 9 inches of Portland cement concrete, over
- 8 inches of new aggregate base course similar in gradation to MDOT 21AA, over
- (only placed where required) Triaxial geogrid such as Tensar NX750 or another engineer approved geogrid equivalent, over
- The compacted existing subgrade soils. Compact the existing subgrade with a vibratory roller or plate compactor until subsequent passes result in no significant downward displacement.

The subgrade and base material should be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D-1557 (Modified Proctor).

Through the interlock restraint mechanism, this recommended system of base material reinforced with one layer of geogrid will provide the following benefits:

- The geogrid will help to tie together the widened paved turns with the pavement of the mainline access drive in order to avoid differential settlement since these areas have not been pre-consolidated by traffic load as the mainline road has experienced in the past.
- The geogrid system will help minimize the undercutting at localized areas of the existing fill soils (such as the organic pocket noted at 3 feet depth at the location of boring SB-03) and hence will reduce the additional earthwork costs. We still however recommend the normal practice that once rough subgrade has been exposed that any visible organic pockets be removed to the full vertical extent prior to placing the geogrid and the new base material course. A geotechnical engineer or qualified technician should confirm the suitability of the subgrade soils in the field at the time of construction.

To avoid differential settlement and pavement cracking at these widened turns, we recommend the geogrid to be placed immediately below the new 21AA base material and should span laterally from edge of pavement to edge of pavement with a minimum two feet extension beyond the outer (widened) edge. Longitudinally along the road, the geogrid should extend a minimum of 3 feet on either end of the widened section.

If needed, we recommend a 2-foot minimum overlap of the geogrid in conformance with manufacturer's recommendations to promote continuity of its load distribution performance.

The nominal size of the Tensar triaxial NX750 geogrid roll consists of 197 feet long and 12.5 feet wide geogrid strip that is generally commonly available and in stock. The standard specification of Tensar NX750 is attached in Appendix F for reference. An equivalent alternative to the Tensar

NX750 may be used as approved by the engineer provided it is co-extruded and has similar aperture size and shape.

4.2 PROPOSED BIOSWALE

As we understand, there are areas around the CSO basin that are poorly drained. On the basin's west side, there is an existing shallow drainage swale with dimensions of approximately 360 feet by 30 feet. The current plan calls for expanding and improving this swale to increase its volume to accept the flow that is discharged from the west side of the basin roof during wet weather.

A total of three (3) hand auger probes were performed along the existing bioswale. These probes were SB-04, 05, and 06 and each extended to a depth of 6 feet, 4 feet, and 5 feet, respectively.

Based on the findings of the hand auger probes, the soils consisted of 6 inches of topsoil over a granular fill layer over the native clay. The granular fill layer encountered in probes SB-04 and SB-05 consisted of silty sand and clayey sand soils, and had a thickness of 4 and 18 inches, respectively. Laboratory grain size analysis performed in accordance with ASTM D6913 indicated that the fines content of this granular layer was 43%, which is considered excessive.

In-situ falling head permeability tests were performed in the native clay soils at the termination depths near the probes. The infiltration tests were performed in offset boreholes within 2 feet from the locations of the sampling probes per the guidelines of the City of Detroit stormwater manual. Based on the in-situ infiltration tests the mean hydraulic conductivity (K1) of the native clay ranged between 0.007 and 0.025 inch per hour, which is considered almost impermeable.

Based on the findings of the infiltration tests, we recommend undercutting the existing granular fill soils and some of the native clays and replacing with drainable engineered fill in conformance to the Green Infrastructure Solution (GIS) design. The geometry of the new expanded swale (length, width, depth, and thickness of the granular soils) shall be designed by the GIS Engineer based on the maximum anticipated surface water runoff at the site.

The GIS design engineer should also consider the level of the anticipated long-term groundwater at the site during the design of the bioswale and the associated drainage systems. Based on the findings at the time of the geotechnical investigation (December 2022), the long-term groundwater table is estimated to be situated at a depth of about 3.3 to 4 feet below existing grades ((EL. 95 to 99 feet $\pm$)).

5.0 GENERAL QUALIFICATIONS

All construction activities should be monitored under the direction of a qualified Geotechnical Engineer to verify conditions as interpreted in this report. This report and the attached Logs of Auger Probes are instruments of service, which have been prepared in accordance with generally accepted soil and foundation engineering practices. We make no other warranties either expressed or implied as to the professional advice included in this report.

The contents of this report have been selected in order to aid in the evaluation of expected subsoil properties to assist the Engineer in the design of this project. In the event that any changes are made in the geotechnical aspects of this project, however slight, the conclusions and recommendations contained in this report shall not be considered valid unless the changes are reviewed, and the conclusions of this report are modified in writing by our office.

Since the information obtained from auger probes is specific to the exact test locations, soil and water information could be different from those occurring at other locations of the site. This report does not reflect variations which may occur between the test holes. The nature and extent of these variations may not become evident until the time of construction. If significant variations then become evident, it may be necessary for us to re-evaluate the recommendations provided in this report.

This report and the associated soil logs should be made available to bidders prior to submitting their proposals and to the successful Contractor and subcontractors for their information only, and to supply them with facts relative to the subsurface investigation, laboratory tests, etc.

The discussions and recommendations submitted in this report are based on the soil information contained in the Logs of Auger Probes and test results appended to this report. We expect that the logs of auger probes, test results, and the soil profiles included in this report along with our discussions and conclusions will assist you in designing the proposed pavement. Please refer to Appendix F for important information about this geotechnical investigation report. If you have any questions regarding this report, please contact us.

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2488 (Modified)

DRILLING & SAMPLING SYMBOLS:

SS:	Split Spoon – 1 3/8" I.D., 2" O.D. (standard)	BS:	Bulk Sample	RC:	Rock Core with diamond bit, NX size, (unless otherwise noted)
S:	Split Spoon – non-standard size, as noted	HSA:	Hollow Stem Auger		
ST:	Thin-Walled Tube – 3" O.D., (unless otherwise noted)	DP:	Direct Push	RB:	Rock Bit/Roller Bit
LS:	Liner Sample	PS:	Piston Sample	WR:	Wash Rotary
PA:	Power Auger	PT:	Pitcher Sample	NR:	No Recovery
HA:	Hand Auger	WS:	Wash Sample	VS:	Vane Shear Test
AU:	Auger Sample			ER:	Hammer Energy Ratio

Standard Penetration Test Resistance, N-Value: Sum of 2nd and 3rd 6-inch increments, in blows per foot of a 140-pound hammer falling 30 inches and driving an 18-inch to 30-inch long, 2-inch OD split spoon.

WATER LEVEL MEASUREMENT:

Water levels indicated on the boring logs are the levels measured in the borings at the times indicated. In pervious soils, the indicated levels may reflect the location of a groundwater table. In low permeability soils (clays and silts), the accurate determination of groundwater levels may not be possible with only short-term observations. Groundwater levels at times and locations other than when and where individual borings were performed could vary.

DESCRIPTIVE SOIL CLASSIFICATION:

Soil classification is based on the Unified Soil Classification (USC) System and ASTM Standards D-2487 and D-2488. Coarse-grained soils have more than 50% of their dry weight retained on a #200 sieve; they are described as: gravel or sand. Fine-grained soils have less than 50% of their dry weight retained on a #200 sieve; they are generally described as: clays, if they are plastic, and silts, if they are slightly plastic or non-plastic. Major constituents may be added as modifiers and minor constituents may be added according to the relative proportions based on grain size. In addition to gradation, coarse-grained soils are defined on the basis of their apparent in-place density and fine-grained soils on the basis of their apparent in-place density (silty soils) or consistency (clayey soils).

CONSISTENCIES OF COHESIVE SOILS:

The pocket penetrometer, pocket torvane, and in-situ vane shear tests are converted into an estimated unconfined compressive strength, in pounds per square feet (psf), for presentation on the logs. The unconfined compressive strength is estimated to be about two time the shear strength.

DESCRIPTORS OF MINOR CONSTITUENTS

Primary Constituent	Fine-Grained (Silt & Clay)	Coarse-Grained (Sand & Gravel)	
Descriptor of Other Constituents	Relative Portion of Coarse Grained Soils as a % of Dry Weight	Relative Portion of Fine Grained Soils as a % of Dry Weight	Relative Portion of Coarse Grained Soils as a % of Dry Weight
Trace	<5%	<5%	<5%
Few	≥5% - <15%	N/A	≥5% - <15%
With	≥15% - <30%	≥5% - 12%	≥15%
Modifier	≥30%	>12%	N/A

FINE-GRAINED SOILS

Unconfined Compressive Strength Q_u , psf	Consistency	N-Value	Apparent Density
< 500	Very Soft	0 – 4	Very Loose
500 - <1,000	Soft	5 – 9	Loose
1,000 - <2,000	Medium	10 – 29	Medium Dense
2,000 - <4,000	Stiff	30 – 49	Dense
4,000 - <8,000	Very Stiff	50 – 80	Very Dense
≥ 8,000	Hard	>80	Extremely Dense

COARSE-GRAINED SOILS

DEFINITIONS OF PAVEMENT CONDITION

Condition	Description
Good	ACC Very slight or no raveling, surface shows some traffic wear. Longitudinal cracks and transverse cracks (open ¼ inch). No patching or very few patches in excellent condition.
	PCC Moderate scaling in several locations. A few isolated surface spalls. Shallow reinforcement causing cracks. Several corner cracks, tight or well sealed. Open (¼ inch wide) longitudinal or transverse joints.
Fair	ACC Severe surface raveling. Multiple longitudinal and transverse cracking with slight raveling. Longitudinal cracking in wheel path. Block cracking (over 50% of surface). Patching in fair condition. Slight rutting or distortions (½ inch deep or less).
	PCC Severe polishing, scaling, map cracking, or spalling over 50% of the area. Joints and cracks show moderate to severe spalling. Pumping and faulting of joints (½ inch with fair ride). Several slabs have multiple transverse or meander cracks with moderate spalling.
Poor	ACC Alligator cracking (over 25% of surface). Severe distortions (over 2 inches deep) Extensive patching in poor condition. Potholes.
	PCC Extensive slab cracking, severely spalled and patched. Joints failed. Patching in very poor condition. Severe and extensive settlement or frost heaves.

DEFINITIONS OF STRUCTURAL AND DEPOSITIONAL FEATURES

Term	Definition
Parting	≤ 1/16 inch (1.6 mm) thick
Seam	> 1/16 inch (1.6 mm) → ½ inch (12.7 mm) thick
Layer	> ½ inch (12.7 mm) to ≤ 12 inches (305 mm) thick
Pocket	Small, erratic deposits of limited lateral extent
Lens	Lenticular deposit
Lensed	Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay
Varved	Alternating partings or seams (1 mm – 12 mm) of silt and/or clay and sometimes fine sand
Stratified	Alternating layers of varying material or color with layers ≥ 6 mm thick
Laminated	Alternating layers of varying material or color with layers < 6 mm thick
Fissured	Contains shears or separations along planes of weakness
Slickensided	Shear planes appear polished or glossy, sometimes striated
Blocky	Cohesive soil that can be broken down into small angular lumps which resist further breakdown
Homogeneous	Same color and appearance throughout
Occasional	One or less per foot (305 mm) of thickness
Frequent	More than one per foot (305 mm) of thickness
Interbedded	Applied to strata of soil lying between or alternating with other strata of a different nature

GRAIN SIZE TERMINOLOGY

Major Component of Sample	Size Range
Boulders	≥ 12" (300 mm)
Cobbles	< 12" - 3" (300 mm – 75 mm)
Gravel - Coarse	< 3" - ¾" (75 mm – 19 mm)
Gravel - Fine	< ¾" - #4 (19 mm – 4.75 mm)
Sand - Coarse	< #4 - #10 (4.75 mm – 2 mm)
Sand - Medium	< #10 - #40 (2 mm - 0.425 mm)
Sand - Fine	< #40 - #200 (0.425 mm - 0.074 mm)
Silt	< 0.074 mm - 0.005 mm
Clay	< 0.005 mm

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2487

Criteria for Assigning Group Symbols and Group Names Using Laboratory Tests ^A				Soil Classification	
				Group Symbol	Group Name <i>B</i>
COARSE-GRAINED More than 50 % retained on No. 200 sieve	Gravels (More than 50 % of coarse fraction retained on No. 4 sieve)	Clean Gravels	$Cu \geq 4$ and $1 \leq Cc \leq 3^D$	GW	Well-graded gravel ^E
		(Less than 5% fines ^C)	$Cu < 4$ and/or $[Cc < 1$ or $Cc > 3]^D$	GP	Poorly graded gravel ^E
		Gravels with Fines	Fines classify as ML or MH	GM	Silty gravel ^{E,F,G}
		(More than 12 % fines ^C)	Fines classify as CL or CH	GC	Clayey gravel ^{E,F,G}
	Sands (50 % or more of coarse fraction passes No. 4 sieve)	Clean Sands	$Cu \geq 6$ and $1 \leq Cc \leq 3^D$	SW	Well-graded sand ^F
		(Less than 5 % fines ^H)	$Cu < 6$ and/or $[Cc < 1$ or $Cc > 3]^D$	SP	Poorly graded sand ^F
		Sands with Fines	Fines classify as ML or MH	SM	Silty sand ^{F,G,I}
		(More than 12 % fines ^H)	Fines classify as CL or CH	SC	Clayey sand ^{F,G,I}
FINE-GRAINED SOILS 50 % or more passes the No. 200 sieve	Silts and Clays Liquid limit less than 50	inorganic	$PI > 7$ and plots on or above "A" line ^J	CL	Lean clay ^{K,L,M}
			$PI < 4$ or plots below "A" line ^J	ML	Silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OL	Organic clay ^{K,L,M,N} Organic silt ^{K,L,M,O}
	Silts and Clays Liquid limit more than 50	inorganic	PI plots on or above "A" line	CH	Fat clay ^{K,L,M}
			PI plots below "A" line	MH	Elastic silt ^{K,L,M}
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OH	Organic clay ^{K,L,M,P} Organic silt ^{K,L,M,Q}
HIGHLY ORGANIC SOILS	Primarily organic matter, dark in color, and organic odor			Pt	Peat
^A Based on the material passing the 3-in. (75-mm) sieve. ^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name. ^C Gravels with 5 to 12 % fines require dual symbols: GW-GM well-graded gravel with silt GW-GC well-graded gravel with clay GP-GM poorly graded gravel with silt GP-GC poorly graded gravel with clay ^D $Cu = D_{60} / D_{10}$ $Cc = (D_{30})^2 / (D_{10} \times D_{60})$ ^E If soil contains ≥ 15 % sand, add "with sand" to group name. ^F If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM. ^G If fines are organic, add "with organic fines" to group name.				^H Sands with 5 to 12 % fines require dual symbols: SW-SM well-graded sand with silt SW-SC well-graded sand with clay SP-SM poorly graded sand with silt SP-SC poorly graded sand with clay ^I If soil contains ≥ 15 % gravel, add "with gravel" to group name. ^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay. ^K If soil contains 15 to < 30 % plus No. 200, add "with sand" or "with gravel," whichever is predominant. ^L If soil contains ≥ 30 % plus No. 200, predominantly sand, add "sandy" to group name. ^M If soil contains ≥ 30 % plus No. 200, predominantly gravel, add "gravelly" to group name. ^N $PI \geq 4$ and plots on or above "A" line. ^O $PI < 4$ or plots below "A" line. ^P PI plots on or above "A" line. ^Q PI plots below "A" line.	

^A Based on the material passing the 3-in. (75-mm) sieve.

^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name.

^C Gravels with 5 to 12 % fines require dual symbols:

GW-GM well-graded gravel with silt
GW-GC well-graded gravel with clay
GP-GM poorly graded gravel with silt
GP-GC poorly graded gravel with clay

^D $Cu = D_{60}/D_{10}$ $Cc = (D_{30})^2 / (D_{10} \times D_{60})$

^E If soil contains ≥ 15 % sand, add "with sand" to group name.

^F If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM.

^G If fines are organic, add "with organic fines" to group name.

^H Sands with 5 to 12 % fines require dual symbols:

SW-SM well-graded sand with silt
SW-SC well-graded sand with clay
SP-SM poorly graded sand with silt
SP-SC poorly graded sand with clay

^I If soil contains ≥ 15 % gravel, add "with gravel" to group name.

^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay.

^K If soil contains 15 to < 30 % plus No. 200, add "with sand" or "with gravel," whichever is predominant.

^L If soil contains ≥ 30 % plus No. 200, predominantly sand, add "sandy" to group name.

^M If soil contains ≥ 30 % plus No. 200, predominantly gravel, add "gravelly" to group name.

^N $PI \geq 4$ and plots on or above "A" line.

^O $PI < 4$ or plots below "A" line.

^P PI plots on or above "A" line.

^Q PI plots below "A" line.

Order of Classification: 1) Consistency or Apparent Density, 2) Type of Soil, 3) Minor Soil Type(s), 4) Inclusions, 5) Layered Soils, 6) Color, 7) Water Content, 8) USCS Symbol, 9) Geological Name

ATTERBERG LIMITS RESULTS

PROJECT NO. 2022136A

[illegible]

Description of Frequently Used Laboratory Testing Procedures

Visual Engineering Classification

Visual classification was performed on all samples (though other means of refining the classification may also be used). The General Notes provided immediately following the Logs of Test Borings include a brief discussion of the general method used to visually classify the soil, which is based on the visual-manual procedure (ASTM D2488). The visual classification is used to assign an appropriate Unified Soil Classification System (USCS) group symbol. The USCS symbol is shown in parentheses following the textural description of the various strata on the boring logs.

Where more laboratory testing is performed (requiring both grain size and Atterberg limit tests), the classification may also be refined further based on USCS ASTM D2487.

Moisture Content (ASTM D2216)

Moisture content determination tests were performed in accordance with ASTM D2216. Samples were sealed in the field to retain the natural moisture content of the soil specimen. Samples were then dried at a constant temperature (approximately 110° C) overnight in an oven. After drying, the samples were weighed to determine the dry weight of the sample (and the loss in weight representing the water contained in the original sample). The moisture content of the specimen is expressed as a percent and is the weight of the water compared to the dry weight of the specimen.

Hand Penetrometer

A hand/pocket penetrometer was used to estimate the unconfined compressive strength of cohesive (clay) samples. In the hand penetrometer test, the shear strength of a cohesive soil sample is estimated by measuring the resistance of the sample to the penetration of a small, calibrated spring-loaded cylinder. The maximum capacity of the penetrometer is 4.5 tons per square foot. The shear strength is doubled and reported on the soil boring logs as an estimate of the unconfined compressive strength.

Grain Size Analyses (ASTM D6913, D7928, and/or D422-2017)

Grain size analyses were performed in accordance with ASTM D6913, D7928, and/or D422-2017 on selected soil samples to evaluate the gradation of the soil represented by the sample. The distribution of particle sizes larger than 75 micrometers (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 75 micrometers is determined by a sedimentation process using a hydrometer.

Atterberg Limits Tests (ASTM D4318)

Determination of the Liquid Limit, Plastic Limit, and Plasticity Index of cohesive soils (known as Atterberg Limits) were performed in accordance with ASTM D4318. Fine-grained soils are tested to determine the Liquid Limit (LL) and Plastic Limits (PL), which are moisture contents that define boundaries between material consistency states. The LL and PL values define the transitional boundaries between non-plastic, plastic, and viscous fluid states. The plasticity index (PI) defines the complete range in water content for the plastic state.

Description of Frequently Used Laboratory Testing Procedures (continued)

Organic Content (Loss-On-Ignition) Tests (ASTM D7348)

The organic content of a soil is determined through a Loss-On-Ignition test performed in accordance with ASTM D2974 on soil samples suspected to contain significant organics. After the sample has been oven-dried, the soil sample is super-heated in a 440°C muffle furnace as a means to burn off all present organic matter. The weight of the remaining ash is used to calculate the percentage of organic matter as compared to the dry weight of the sample.

APPENDIX F

STANDARD SPECIFICATIONS FOR TRIAXIAL GEOGRID BY TENSAR NX750

Product Data Sheet InterAx™ NX750™ Geogrid

Tensar International Corporation reserves the right to change its product specifications at any time. It is the responsibility of the person specifying the use of this product and of the purchaser to ensure that product specifications relied upon for design or procurement purposes are current and that the product is suitable for its intended use in each instance.

General

- The geogrid is manufactured from a coextruded, composite polymer sheet, which is then punched and oriented. The resulting structure consists of continuous and non-continuous ribs forming three aperture geometries (hexagon, trapezoid, and triangle) and an unimpeded suspended hexagon.

Tensar NX750 Geogrid
Plan View

Tensar NX750 Geogrid
Perspective View

- The following properties are intended for product identification:

Identification Properties ¹	General
- Aperture shapes - Structure - Rib shape - Continuous parallel rib pitch⁽²⁾, mm (in) - Rib aspect ratio⁽³⁾ - Node thickness⁽²⁾, mm (in) - Color identification	Hexagonal, Trapezoidal, & Triangular Coextruded & Integrally Formed Rectangular 80 (3.2) > 1.0 3.5 (0.14) White / Black / White

Dimensions and Delivery

The geogrid shall be delivered to the jobsite in roll form with each roll individually identified as NX750 (aka, XPG5560 or NextGen-A). Rolls are shipped with nominal measurements: Equal to 3.8 meters (12.5 feet) in width by 60 meters (197 feet) in length.

Notes

- Unless indicated otherwise, values shown are minimum average roll values determined in accordance with ASTM D4759-02
- Nominal dimensions
- Ratio of the mid-rib depth to the mid-rib width

GEO-PROFESSIONAL BUSINESS ASSOCIATION (GBA) MESSAGE

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, you can benefit from a lowered exposure to problems associated with subsurface conditions at project sites and development of them that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed herein, contact your GBA-member geotechnical engineer. Active engagement in GBA exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Understand the Geotechnical-Engineering Services Provided for this Report

Geotechnical-engineering services typically include the planning, collection, interpretation, and analysis of exploratory data from widely spaced borings and/or test pits. Field data are combined with results from laboratory tests of soil and rock samples obtained from field exploration (if applicable), observations made during site reconnaissance, and historical information to form one or more models of the expected subsurface conditions beneath the site. Local geology and alterations of the site surface and subsurface by previous and proposed construction are also important considerations. Geotechnical engineers apply their engineering training, experience, and judgment to adapt the requirements of the prospective project to the subsurface model(s). Estimates are made of the subsurface conditions that will likely be exposed during construction as well as the expected performance of foundations and other structures being planned and/or affected by construction activities.

The culmination of these geotechnical-engineering services is typically a geotechnical-engineering report providing the data obtained, a discussion of the subsurface model(s), the engineering and geologic engineering assessments and analyses made, and the recommendations developed to satisfy the given requirements of the project. These reports may be titled investigations, explorations, studies, assessments, or evaluations. Regardless of the title used, the geotechnical-engineering report is an engineering interpretation of the subsurface conditions within the context of the project and does not represent a close examination, systematic inquiry, or thorough investigation of all site and subsurface conditions.

Geotechnical-Engineering Services are Performed for Specific Purposes, Persons, and Projects, and At Specific Times

Geotechnical engineers structure their services to meet the specific needs, goals, and risk management preferences of their clients. A geotechnical-engineering study conducted for a given civil engineer

will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client.

Likewise, geotechnical-engineering services are performed for a specific project and purpose. For example, it is unlikely that a geotechnical-engineering study for a refrigerated warehouse will be the same as one prepared for a parking garage; and a few borings drilled during a preliminary study to evaluate site feasibility will not be adequate to develop geotechnical design recommendations for the project.

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project or purpose;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, the reliability of a geotechnical-engineering report can be affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying the recommendations in it. A minor amount of additional testing or analysis after the passage of time – if any is required at all – could prevent major problems.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read the report in its entirety. Do not rely on an executive summary. Do not read selective elements only. *Read and refer to the report in full.*

You Need to Inform Your Geotechnical Engineer About Change

Your geotechnical engineer considered unique, project-specific factors when developing the scope of study behind this report and developing the confirmation-dependent recommendations the report conveys. Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the elevation, configuration, location, orientation, function or weight of the proposed structure and the desired performance criteria;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project or site changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept*

responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

Most of the “Findings” Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site’s subsurface using various sampling and testing procedures. *Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing is performed.* The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgement to form opinions about subsurface conditions throughout the site. Actual site-wide subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team through project completion to obtain informed guidance quickly, whenever needed.

This Report’s Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgement and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* exposed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals’ misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a continuing member of the design team, to:

- confer with other design-team members;
- help develop specifications;
- review pertinent elements of other design professionals’ plans and specifications; and
- be available whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction-phase observations.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note*

conspicuously that you’ve included the material for information purposes only. To avoid misunderstanding, you may also want to note that “informational purposes” means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. This happens in part because soil and rock on project sites are typically heterogeneous and not manufactured materials with well-defined engineering properties like steel and concrete. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled “limitations,” many of these provisions indicate where geotechnical engineers’ responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a “phase-one” or “phase-two” environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually provide environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures.* If you have not obtained your own environmental information about the project site, ask your geotechnical consultant for a recommendation on how to find environmental risk-management guidance.

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, the engineer’s services were not designed, conducted, or intended to prevent migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, *proper implementation of the geotechnical engineer’s recommendations will not of itself be sufficient to prevent moisture infiltration.* Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. *Geotechnical engineers are not building-envelope or mold specialists.*

- NOTES:
1. CONTRACTOR TO RUN NEW ELECTRICAL AND INSTRUMENTATION WIRES FROM EXISTING JUNCTION BOXES/NEW TERMINATION BOXES TO EACH PIECE OF EQUIPMENT.
 2. CONTRACTOR TO PROVIDE AND MOUNT NEW TERMINATION PANELS NEAR EXISTING JUNCTION BOXES IN SCREENING BUILDING. 1 PANEL DESIGNATED FOR INSTRUMENTATION, 1 PANEL DESIGNATED FOR POWER.
 3. CONTRACTOR TO FIELD VERIFY EXISTING WIRING AND PULL BACK WIRING FROM MANHOLES TO EXISTING JUNCTION BOXES. RE-TERMINATE WIRES ON TERMINAL BLOCKS AND RUN NEW WIRE FROM TERMINAL BLOCKS TO EXISTING MANHOLES INTO NEW DUCTBANK TO NEW PULL BOXES AND INTO CONDUITS AND DEVICES IN VAULT.
 4. NEW ALARM INPUTS FOR OVATION ARE TO BE ADDED. BACK UP SUMP PUMP RUNNING (11A AND 14A), AND HIGH SUMP LEVEL ALARM FOR DRAIN VAULT AND DRAIN TO NWI METER VAULT ARE TO BE WIRED INTO THE EXISTING OVATION CABINET ON THE SECOND FLOOR IN THE CONTROL ROOM. GLWA WILL PROVIDE THE OVATION PROGRAMMING.
 5. THE 1" LIGHTING CIRCUIT CONDUIT AND THE 1" RECEPTACLE CIRCUIT CONDUIT FRO THE DRAIN TO NWI VAULT SHALL REMAIN AND BE RE-USED. THE EXISTING CONDUIT FOR THESE CIRCUITS MAY ALSO BE RE-USED. CONTRACTOR TO PULL BACK WIRE AND INSPECT FOR DAMAGE. CLEAN CONDUIT AND REPAIR ANY DAMAGE. RECEPTACLES AND LIGHT FIXTURES ARE NOT TO BE RE-USED AND ARE TO BE REPLACED IN KIND.
 6. IF ANY OF THE WIRING FOR THE LIGHTS OR RECEPTACLES NEEDS TO BE REPLACED, THE CONTRACTOR SHALL DO SO.
 7. REMOVE EXISTING JUNCTION BOX ON EAST WALL OF DRAIN VAULT BELOW GRADE.
 8. ADD NEW SUMP PUMP CONTROL PANEL ABOVE GRADE NEXT TO EXISTING SUMP PUMP CONTROL PANEL.
 9. ROUTE NEW CIRCUITS FROM LP-3 IN CONTROL ROOM TO NEW POWER DISTRIBUTION EQUIPMENT AND NEW SUMP PUMP CONTROL PANELS.
 10. INSTALL NEW VALVE OPERATOR STATIONS AND WIRING ABOVE GRADE ON TOP OF DRAIN VAULT.
 11. NEW DISCONNECT SWITCH TO BE NEMA 3R STAINLESS STEEL.
 12. NEW 5KVA TRANSFORMER AND POWER DISTRIBUTION CENTER TO BE RATED NEMA 3R MINIMUM.

PULL BOXES TO BE SECURELY INSTALLED ON S.S. UNISTRUT TO KEEP OFF OF CONCRETE. PICTURE MAY NOT ACCURATELY PORTRAY SIZE OF THESE BOXES

CIVIL GENERAL NOTES:

1. STORM SEWER PIPE: C76-CL IV CONCRETE PIPE FOR 12" DIA. AND ABOVE.
C14-CL III CONCRETE PIPE FOR 10" AND BELOW.

SANITARY SEWER PIPE: SCHEDULE 40 PVC PIPE.

WATER LINES: MATERIALS FOR WATER LINE PIPING (FIRE, PW, SW) SHALL BE THE FOLLOWING.
 - DUCTILE IRON PIPE-CLASS 56 WITH CEMENT MORTAR LINING AND RESTRAINED JOINTS FOR PIPE SIZES 4-INCH TO 12-INCH DIAMETER PIPE,CEMENT MORTAR LINING AND RESTRAINED JOINTS AS NOTED IN SPECIFICATION SECTION 02616.
 - PVC SCHEDULE 80 FOR 3-INCH DIAMETER PIPE.
 - K' COPPER FOR 1- $\frac{1}{2}$ INCH DIAMETER PIPE.
2. MINIMUM COVER OF UNDERGROUND UTILITIES:
WATER 6.0 FT.
NAT. GAS 2.5 FT.
SANITARY SEWER AS SHOWN ON PLANS
STORM SEWER AS SHOWN ON PLANS
ALL OTHERS 2.5 FT

PRESSURE UTILITIES MAY BE LAID APPROXIMATELY PARALLEL TO FINISH GRADE, EXCEPT AS INDICATED, WITH LOCAL DEEPENING TO AVOID OTHER UTILITIES OR OBSTRUCTIONS. MAINTAIN COVER BELOW DITCHES AND SURFACE DEPRESSIONS. PROVIDE TEMPORARY PROTECTION AS REQUIRED UNTIL COVER IS COMPLETED. INFORM OWNER'S REPRESENTATIVE IF AVAILABLE COVER AT INDICATED ELEVATIONS IS LESS THAN MINIMUM.
3. TOPOGRAPHICAL INFORMATION: EXISTING INFORMATION IS BASED ON A TOPOGRAPHICAL SURVEY BY: SPALDING DeDECKER ASSOCIATES, INC. SUPPLEMENTED BY RECORD DRAWINGS AND FIELD OBSERVATION.
4. VERTICAL CONTROL: BENCH MARKS SHOWN ON DWG. D-04-08-006
5. THE GENERAL CONTRACTOR MUST VISIT THE SITE PRIOR TO SUBMITTING A BID ON THIS PROJECT TO FAMILIARIZE HIMSELF WITH SHOWN OR NOT SHOWN EXISTING CONDITIONS. ANY EXISTING CONDITIONS FOUND AS VARIANCE WITH THESE DRAWINGS MUST BE IMMEDIATELY REPORTED TO THE OWNER.
6. THE CONTRACTOR SHALL MAINTAIN ONE (1) CLEAN SET OF MARKED PLANS SHOWING ALL CHANGES AND "AS BUILT" INFORMATION WHICH WILL BE SUBMITTED TO THE DESIGN ENGINEER UPON COMPLETION OF WORK.
7. PROVIDE TEMPORARY EROSION CONTROL MEASURES AS REQUIRED BY LOCAL AND/OR STATE AGENCIES HAVING JURISDICTION AND AS SHOWN ON PLAN.
8. ALL IMPORTED FILL MATERIAL MUST BE CLEAN GRANULAR SOIL FREE FROM TRASH, LUMBER, DELETERIOUS OR FROZEN MATERIALS.
9. ALL WORK TO BE PERFORMED AS PER CITY OF DETROIT AND WAYNE COUNTY REQUIREMENTS.
10. EXISTING UTILITIES: INFORMATION HAS BEEN OBTAINED FROM EXISTING AVAILABLE DRAWINGS AND SURFACE FEATURES SHOWN ON THE TOPOGRAPHICAL SURVEYS. VERIFY THE INFORMATION BEFORE START OF CONSTRUCTION. NOTIFY THE OWNER'S REPRESENTATIVE OF DISCREPANCIES OR INTERFERENCES.
11. CONSTRUCTION DRAINAGE: USE PUMPS, TEMPORARY DITCHES, SLOPES TO MAINTAIN A WELL DRAINED SITE, FREE OF STANDING WATER AND WATER SOFTENED SOILS.
12. LAYOUT: CONFIRM HORIZONTAL AND VERTICAL CONTROL POINTS PRIOR TO CONSTRUCTION.
13. SURFACE RESTORATION: RESTORE PAVEMENT AND OTHER SURFACES DISTURBED BY CONTRACT OPERATIONS TO THEIR ORIGINAL CONDITIONS OR BETTER.
14. SOIL BORINGS: SOILS INFORMATION IS PROVIDED. THE BORING LOGS SHOW SUBSURFACE CONDITIONS AT THE DATES AND LOCATIONS INDICATED, AND IT IS NOT WARRANTED THAT THEY ARE REPRESENTATIVE OF SUBSURFACE CONDITIONS AT OTHER LOCATIONS AND TIMES. THE CONTRACTOR MAY AT HIS OWN COST PERFORM ADDITIONAL SOIL BORINGS PRIOR TO BIDDING.
15. ALL ELEVATIONS SHOWN ARE SURFACE ELEVATION AND AS INDICATED ON PLANS.
16. SLOPE SMOOTHLY BETWEEN INDICATED ELEVATIONS TO PROVIDED POSITIVE DRAINAGE OF ALL AREAS GRADED OR DISTURBED BY THIS CONTRACT.
17. COMPLY WITH THE CONSTRUCTION SAFETY STANDARDS AND THE OCCUPATIONAL SAFETY STANDARDS AS ISSUED BY THE US DEPARTMENT OF LABOR AND LOCAL AUTHORITIES HAVING JURISDICTION.
18. VERIFY FIELD CONDITIONS BEFORE STARTING WORK AND REPORT VARIATIONS TO OWNER'S REPRESENTATIVE.
19. BE FAMILIAR WITH EXISTING CONDITIONS AT SITE, INCLUDING UTILITIES AND SERVICES AND BE RESPONSIBLE FOR DAMAGES CAUSED TO BOTH EXISTING AND NEW CONSTRUCTION AND PROPERTY AND FOR UNAUTHORIZED DISRUPTION TO ADJACENT OWNERS NORMAL USE OF UTILITIES, SERVICES, AND SURROUNDING FACILITIES.
20. PROVIDE BARRIER PROTECTION FOR VEHICULAR AND PEDESTRIAN TRAFFIC AT EXCAVATIONS. TEMPORARY FENCING, BARRICADING AND PEDESTRIAN ROUTING SHALL BE COORDINATED WITH AND APPROVED BY OWNER'S REPRESENTATIVE PRIOR TO CONSTRUCTION.
21. DEMOLISHED MATERIALS: TOP SOILS, ORGANIC CONTAMINATED, WET SOILS OR OTHER DELETERIOUS MATERIALS MUST BE REMOVED FROM SITE. ANY EXISTING SOILS SUITABLE FOR USE AS FILL MAY BE RETAINED AND REINSTALLED AS COMPACTED FILL. REMOVAL OF THESE MATERIALS SHALL BE DONE AT NO ADDITIONAL COST TO THE OWNER.
22. THE CONTRACTOR SHALL DISPOSE OF ALL SURPLUS EXCAVATION AND/OR PROVIDE ALL SUITABLE FILL MATERIALS AS APPROVED BY THE SOILS ENGINEER AND COST SHALL BE INCLUDED IN THE PRICE BID FOR THE RELATED ITEMS.
23. ALL DISTURBED AREAS NOT RECEIVING PAVEMENT OR GRANULAR MATERIALS SHALL RECEIVE SEED, FERTILIZE AND MULCH OR AS INDICATED ON DRAWINGS.
24. ALL MANHOLES, CATCH BASINS, INLETS, OR SIMILAR DRAINAGE STRUCTURES IN PAVED AREAS TO HAVE 4" DIA - 10 FT. LONG PERFORATED UNDERDRAIN PIPES WRAPPED IN FILTER FABRIC IN FOUR DIRECTIONS (TWO DIRECTIONS IN UNPAVED AREA) AND RECESSED BENEATH THE AGGREGATE BASE LAYER.
25. FOR ADDITIONAL BOLLARDS SEE ARCHITECTURAL DRAWINGS.

SOIL EROSION CONTROL STAGING:

THE FOLLOWING STAGING IS INTENDED TO BE A GENERAL METHOD OF CONSTRUCTION. ANY OPERATIONS DESCRIBED HEREIN WHICH DO NOT ADVERSELY AFFECT SUBSEQUENT STAGING OR THE INTENT OF SOIL EROSION AND SEDIMENT CONTROL MAY BE PERFORMED AT THE CONTRACTOR'S CONVENIENCE WITH THE APPROVAL OF THE WAYNE COUNTY DEPARTMENT OF ENVIRONMENT, LAND RESOURCES MANAGEMENT DIVISION, WATERSHED MANAGEMENT DIVISION.

1. INSTALL STRAW BALE FILTER OR GEOTEXTILE SILT FENCE ALONG THE PERIMETER OF PROPERTY OR CONSTRUCTION AREA AS PER DETAILS THIS SHEET.
2. INSTALL SEDIMENT CONTROL MEASURES AT ALL EXISTING DRAINAGE STRUCTURES AS INDICATED PRIOR TO START OF WORK, AS PER DETAIL THIS SHEET.
3. PERFORM GRADING OPERATIONS AS REQUIRED.
4. TEMPORARILY MULCH ALL DISTURBED AREAS OR APPLY PERMANENT EROSION CONTROL MEASURES WITHIN 15 DAYS AFTER THE EARTH DISRUPTION.
5. ESTABLISH PERMANENT EROSION CONTROL MEASURES SUCH AS SEED AND MULCH, SOD, ETC., AS INDICATED.
6. REMOVE TEMPORARILY EROSION CONTROL MEASURES UPON PERMANENT STABILIZATION OF ALL DISTURBED AREAS.

SILT FENCE NOTES:

1. SILT FENCE AND FILTER FABRIC MATERIALS SHALL BE PURCHASED IN A CONTINUOUS ROLL. CUT TO THE LENGTH OF THE BARRIER TO AVOID THE USE OF JOINTS.
2. THE HEIGHT OF A SILT FENCE SHALL NOT EXCEED 36 INCHES (HIGHER FENCES MAY IMPOUND VOLUMES OF WATER SUFFICIENT TO CAUSE FAILURE OF THE STRUCTURE).
3. POST SHALL BE SPACED A MAXIMUM OF 6 FEET APART AT THE BARRIER LOCATION AND DRIVEN SECURELY INTO THE GROUND (MINIMUM 12 INCHES).
4. A TRENCH SHALL BE EXCAVATED APPROXIMATELY 4 INCHES WIDE AND 4 INCHES DEEP FOR THE FILTER FABRIC MATERIAL ALONG THE LINE OF POSTS, UPSLOPE FROM THE FENCE.
5. THE TRENCH SHALL BE BACKFILLED AND THE SOIL COMPACTED OVER THE FILTER MATERIAL. SILT FENCES HAVE THEIR APPLICABILITY LIMITED TO SITUATIONS WHICH ONLY SHEET OR OVERLAND FLOWS ARE EXPECTED.
6. SILT FENCES SHALL BE REMOVED WHEN THEY HAVE SERVED THEIR USEFUL PURPOSE, BUT NOT BEFORE THE UPSLOPE AREA HAS BEEN PERMANENTLY STABILIZED.
7. THE CONTRACTOR SHALL MAINTAIN SILT FENCE UNTIL UPSLOPE AREA HAS BEEN PERMANENTLY STABILIZED.
8. SILT FENCES SHALL BE INSPECTED IMMEDIATELY AFTER EACH RAINFALL AND AT LEAST DAILY DURING PROLONGED RAINFALL. ANY REQUIRED REPAIRS SHALL BE MADE IMMEDIATELY.
9. SHOULD THE FABRIC ON THE SILT FENCE DECOMPOSE OR BECOME INEFFECTIVE PRIOR TO THE END OF THE EXPECTED USABLE LIFE AND THE FENCE IS STILL NECESSARY, THE FABRIC SHALL BE REPLACED PROMPTLY.
10. SEDIMENT DEPOSITS SHOULD BE REMOVED AFTER EACH STORM EVENT. THEY MUST BE REMOVED WHEN DEPOSITS REACH APPROXIMATELY ONE-HALF THE HEIGHT OF THE FENCE.
11. ANY SEDIMENT DEPOSITS REMAINING IN PLACE AFTER THE SILT FENCE IS NO LONGER REQUIRED SHALL BE DRESSED TO CONFIRM WITH THE EXISTING GRADE, PREPARED AND SEEDED.

EROSION CONTROL GENERAL NOTES:

1. ALL PROPOSED WORK SHALL BE IN ACCORDANCE WITH THE SOIL EROSION AND SEDIMENTATION CONTROL PERMIT AND ACT 347 OF THE PUBLIC ACTS OF 1972, AS AMENDED.
2. CONTRACTOR SHALL EMPLOY A QUALIFIED INSPECTOR/TECHNICIAN TO REGULARLY INSPECT THE PROJECT EROSION CONTROL MEASURES. THE INSPECTOR/TECHNICIAN SHALL THOROUGHLY INSPECT EVERY 7 DAYS, OR WITHIN 24 HOURS OF A ONE-HALF INCH RAINFALL, SHALL MAINTAIN A PROJECT NOTEBOOK WITH NAMES, DATES, LOCATIONS AND CORRECTIVE MEASURES. RECORDS SHALL BE MADE AVAILABLE TO THE CITY OR COUNTY INSPECTORS UPON REQUEST.
3. A DIVERSION SWALE (OPTION 'A') AND/OR A SILT FENCE (OPTION 'B') SHALL BE CONSTRUCTED AROUND THE PERIMETER ONE FOOT INSIDE THE PROPERTY LINE. FOR OPTION 'A', IF SWALE CANNOT BE CONSTRUCTED BETWEEN PROPERTY LINE AND PROPOSED EXCAVATION/WORK, THEN EXISTING GROUND SHALL BE SLOPED WITH A MINIMUM OF 2 ON 1 SLOPE FROM PROPERTY LINE TO THE EXCAVATION/WORK. OPTION 'A' SHALL HAVE A MINIMUM OF 0.50% LONGITUDINAL SLOPE.
4. SILT FENCE SHALL REMAIN IN PLACE UNTIL COMPLETION OF PAVEMENT. ALL FLOWS SHALL BE SILT-FREE PRIOR TO DISCHARGE. DISCHARGE SHALL BE DIRECTED TO STABILIZED SITES SUCH AS STREAMS, STORM SEWERS OR EXISTING GRASSED DRAINAGE WAYS NOT ONTO EXPOSED SOILED OR ANY OTHER SITE WHERE FLOWS COULD CAUSE EROSION.
5. PUMPS TO DE-WATER EXCAVATIONS AND DIVERSION SWALES SHALL BE EQUIPPED WITH A FILTER WRAP INLET SCREEN. WHEN SO EQUIPPED PUMP DISCHARGE TO EXISTING SEWER MANHOLE IS ACCEPTABLE.
6. SEDIMENT CONTROL PRACTICES SHALL BE FUNCTIONAL THROUGHOUT PHASES OF EARTH DISTURBING ACTIVITY AND SHALL CONTINUE TO FUNCTION UNTIL DISTURBED AREA IS PERMANENTLY RESTABILIZED.
7. INLET FILTERS SHALL BE INSTALLED AT ALL INLETS AND CATCH BASINS. FILTERS TO REMAIN IN PLACE UNTIL PAVING OCCURS.
8. DISTURBED AREAS WITHIN THE SITE NOT PAVED OR OTHERWISE TO BE LEFT UNDISTURBED FOR 30 DAYS OR MORE SHALL BE TEMPORARILY SEEDED, FERTILIZED AND MULCHED, TO BE APPLIED WITHIN NO MORE THAN SEVEN (7) DAYS AFTER COMPLETION OF EARTHWORK OPERATIONS.
9. EROSION CONTROL SHALL BE INSPECTED BY WAYNE COUNTY DEPARTMENT OF ENVIRONMENT PRIOR TO COMMENCING WITH CONSTRUCTION.
10. SEDIMENT CAUSED BY ACCELERATED SOIL EROSION SHALL BE REMOVED FROM RUNOFF WATER BEFORE IT LEAVES THE SITE.
11. MEASURES SHALL BE TAKEN TO PREVENT SOIL TRANSPORT ONTO SURFACES WHERE RUNOFF IS NOT CHECKED BY SEDIMENT CONTROLS, OR ONTO PUBLIC ROADS. WHERE SOIL IS TRANSPORTED ONTO A PUBLIC ROAD SURFACE, THE ROAD SHALL BE CLEANED THOROUGHLY AT THE END OF EACH DAY, OR MORE FREQUENTLY AS NECESSARY. SOIL SHALL BE REMOVED FROM PAVED SURFACES BY SHOVELING OR SWEEPING. STREET WASHING SHALL BE ALLOWED ONLY AFTER MOST SEDIMENT HAS BEEN REMOVED BY SHOVELING OR SWEEPING.
12. THE ABOVE SPECIFIED EROSION CONTROL STANDARDS ARE GENERAL GUIDELINES AND SHALL NOT LIMIT THE RIGHT OF THE CITY OR THE COUNTY TO IMPOSE, AT ANY TIME, ADDITIONAL, MORE STRINGENT REQUIREMENTS, NOR SHALL THE STANDARDS LIMIT THE RIGHT OF THE CITY OR COUNTY TO WAIVE, IN WRITING, INDIVIDUAL REQUIREMENTS.
13. CONTRACTOR SHALL COORDINATE WORK WITH THE CONSTRUCTION MANAGER AND OTHER CONTRACTORS.

GENERAL SITE/DEMOLITION NOTES:

1. THE GENERAL CONTRACTOR SHALL BE RESPONSIBLE FOR THE FOLLOWING:

A-OBTAINING NECESSARY SOIL EROSION AND SEDIMENTATION CONTROL PERMIT, PLACEMENT AND MAINTENANCE OF SOIL EROSION SEDIMENTATION CONTROL MEASURES.

B-COORDINATING ALL SITE WORK WITH DWSO.

C-LOCATION AND EXTENT OF PROJECT FENCING.

D-LOCATION AND EXTENT OF CONSTRUCTION SPOILS AND STAGING AREAS.

E-LOCATION OF SAWCUTTING/REMOVING EXISTING CURBS, GUTTERS, WALKS AND PAVEMENT.

F-COORDINATING REMOVAL AND/OR TEMPORARY RELOCATION OF EXISTING TREES.

COORDINATES ARE TAKEN ALONG
THE CENTER LINE OF THE CONDUITS

- EFFLUENT CONDUIT NOTES:
1. THE CONTRACTOR SHALL REMOVE THE EXISTING SOIL WITHIN THE LIMITS OF EXCAVATION FOR THE CONDUITS UP TO 2.5 FT BELOW THE BOTTOM OF THE CONDUITS.
 2. THE CONTRACTOR SHALL COMPACT THE SOIL TO 95 % OF THE MAX DRY DENSITY AS DETERMINED BY THE MODIFIED PROCTOR TEST (ASTM D1557). THE CONTRACTOR SHALL REMOVE ANY UNSUITABLE AND ORGANIC MATERIALS AND REPLACE IT WITH ENGINEERED BACKFILL COMPACTED TO 95 % OF THE MAX DRY DENSITY AS DETERMINED BY THE MODIFIED PROCTOR TEST (ASTM D1557).
 3. THE CONTRACTOR SHALL BACKFILL THE EXCAVATED AREA WITH ENGINEERED BACKFILL AS SPECIFIED UP TO 6" BELOW THE BOTTOM ELEVATION OF THE CONDUITS AND CONSTRUCT A 6" MUD MAT.
 4. THE CONTRACTOR SHALL BACKFILL THE TRENCH WITH ENGINEERED BACKFILL AS SPECIFIED UP TO 6" FROM THE FINISHED GROUND ELEVATION.
 5. WITHIN THE EXISTING PUMP STATION LIMITS, THE CONTRACTOR SHALL MAINTAIN 4 FT OF GENERAL GRANULAR BACKFILL BETWEEN THE TOP OF THE BACKFILL MATERIAL AND THE BOTTOM OF THE MUD MAT.
 6. PROVIDE AND INSTALL 24" SERIES 37G INLINE TIDEFLEX CHECK VALVE, NEOPRENE MATERIAL AND 316SS CLAMP INSIDE THE 24" DRAIN PIPE DISCHARGING IN TO THE EXISTING 11"x7' EFFLUENT CONDUIT. THE CONTRACTOR SHALL SUBMIT SHOP DRAWINGS FOR THE ENGINEER'S APPROVAL SHOWING ALL COMPONENTS AND THE ANCHOR BOLTS TO INSTALL THE VALVE INSIDE THE 24" DRAIN PIPE. UPSTREAM PRESSURE IS 2.3 PSI DOWNSTREAM PRESSURE IS 2 PSI.
 7. THE CONTRACTOR SHALL SUBMIT SHOP DRAWING WITH DESIGN CALCULATIONS SIGNED AND SEALED BY A LICENSED PROFESSIONAL ENGINEER IN THE STATE OF MICHIGAN FOR ALL PRECAST UNITS. EFFLUENT CONDUIT UNITS WITHIN THE INFLUENCE OF THE RAILROAD SHALL BE DESIGNED FOR E-80 LOADING.
 8. THE CONTRACTOR SHALL SUBMIT A DETAIL FOR SUPPORTING THE TRACK IN SERVICE WHILE PLACING THE EFFLUENT CONDUIT UNDER THE SECOND TRACK.
 9. THE EFFLUENT CONDUIT WITHIN THE LIMIT OF THE EXISTING PUMP STATION CAN NOT BE CONSTRUCTED UNTIL THE EXISTING PUMP STATION IS DEMOLISHED.
 10. THE MUD MAT SHALL BE CONCRETE 3000 PSI.
 11. A 2,000 GALLON FUEL OIL STORAGE TANK MAY BE LOCATED WEST OF THE EXISTING PUMP STATION, JUST SOUTH OF THE NORTHERN LIMIT OF THE EXISTING PUMP STATION. TANK HAS LIKELY BEEN REMOVED, BUT CONTRACTOR TO DETERMINE IF TANK IS STILL PRESENT. IF PRESENT, A SEPARATE BID ITEM HAS BEEN INCLUDED FOR REMOVAL AND DISPOSAL.
 12. THE EXISTING 4,000 GALLON WASTE OIL STORAGE TANK NEAR THE NORTHEAST CORNER OF THE EXISTING PUMP STATION MUST BE REMOVED BEFORE CONSTRUCTION OF THE EFFLUENT CONDUIT IN THIS VICINITY. SEE SPEC SECTION 01014 REGARDING SEQUENCE OF CONSTRUCTION AND REQUIREMENT TO INSTALL A TEMPORARY ABOVE GROUND STORAGE TANK BEFORE THE EXISTING TANK IS REMOVED.

RECORD DRAWING

THIS RECORD DRAWING HAS BEEN PREPARED BASED ON A COMBINATION OF INFORMATION PROVIDED BY OTHERS AND FIELD SURVEY. THE ENGINEER HAS REVIEWED THE INFORMATION AND BELIEVES IT TO BE THE BEST OF THE ENGINEER'S BELIEF AND KNOWLEDGE. THE INCLUDED RECORD INFORMATION IS REASONABLY ACCURATE.

NOTES:

- EXISTING PUMP STATION SITE PERIMETER FENCE SHALL REMAIN IN SERVICE UNTIL EXISTING PUMP STATION TAKEN OFF-LINE.
- REMOVE EXISTING DWSD MOTORIZED GATE SECURITY EQUIPMENT AND PROVIDE TO DWSD. PROVIDE TEMPORARY MANUALLY OPERATED DOUBLE LEAF GATE SECURED WITH PADLOCK ON THE WESTERN END OF THE SOUTH FENCE TO ALLOW TEMPORARY ACCESS TO THE PUMP STATION DURING CONSTRUCTION OF THE EAST EFFLUENT CONDUIT.
- PRIOR TO EFFLUENT CONDUIT CONSTRUCTION, RELOCATE EXISTING WEST WOLVERINE FENCE AND MOTORIZED GATE TO TEMPORARY EASEMENT LIMIT SHOWN ON DWG 004A. MOTORIZED GATE TO REMAIN MOTOR OPERATED IN THIS TEMPORARY LOCATION. ADD FENCE OF THE SAME TYPE AS EXIST, AS NEEDED, TO WRAP AROUND THE S, N AND W SIDES OF EXIST BUILDING. RELOCATE FENCE AND GATE TO PERMANENT WEST EASEMENT LIMIT AT COMPLETION OF CONSTRUCTION IN THIS AREA. MOTOR OPERATED GATE TO REMAIN MOTOR OPERATED IN PERMANENT LOCATION. THE ABOVE APPLIES TO THE FENCE/GATE BETWEEN THE EXIST SOUTH AND NORTH WOLVERINE FENCES.

EXISTING PUMP STATION DEMOLITION

PLAN

1" = 10'

LEGEND

- ASPHALT AND ALL SUB-BASE TO BE REMOVED AND DISPOSED OF LAWFULLY
- CONCRETE AND ALL SUB-BASE TO BE REMOVED AND DISPOSED OF LAWFULLY
- GRAVEL TO BE REMOVED AND DISPOSED OF LAWFULLY
- FENCE, FENCE POSTS AND CONCRETE FOOTINGS TO BE REMOVED AND DISPOSED OF LAWFULLY

NOTES

- ALL SUITABLE EXISTING TOPSOIL SHALL BE STRIPPED AND STOCKPILED FOR PROJECT USE.

1" = 1'-0"

SECTION 9
1" = 1'-0"

SECTION 10
1" = 1'-0"

SECTION 11
1" = 1'-0"

FLAT GRATE AND FRAME DETAILS
AS NOTED

MATERIAL:
GRAY IRON A.S.T.M. STD. SPEC. A-48, CLASS 30 BEARING SURFACES OF COVER AND FRAME SHALL BE GRIND TO PREVENT ROCKING, CASTING SHALL NOT BE COATED.

PRECAST CONCRETE END SECTION FOR PIPE CULVERT
1" = 1'-0"

SLOPE DETAIL
1" = 1'-0"

PIPE DIA. (IN.)	APPROX. SLOPE	T (IN.)	A (IN.)	B (IN.)	C (IN.)	D (IN.)	E (IN.)	G (IN.)	R (IN.)	X (IN.)	Y (IN.)
12	2.4 TO 1	2	4	24	49	73	24	2	9	8	18
15	2.4 TO 1	2 1/4	6	27	46	73	30	2 1/4	11	8	18
18	2.3 TO 1	2 1/2	9	27	46	73	36	2 1/2	12	8	18

* AS FURNISHED BY THE MANUFACTURER.

- NOTES:**
- CONCRETE IN THESE END SECTIONS SHALL BE THE SAME GRADE AND STRENGTH AS SPECIFIED FOR REINFORCED CONCRETE PIPE, A.S.T.M. DESIGNATION C76 CLASS II, EXCEPT AS MODIFIED BY THE STANDARD SPECIFICATION.
 - REINFORCEMENT IN THE "C" PORTION SHALL BE THE SAME AS SPECIFIED FOR REINFORCED CONCRETE, A.S.T.M. DESIGNATION C76 CLASS II FOR THE SIZE OF CONNECTING PIPE.
 - REINFORCEMENT IN THE "B" PORTION SHALL HAVE A CROSS-SECTIONAL AREA EQUAL TO THAT OF ONE LAYER OF STEEL IN THE "C" PORTION.
 - THE END OF THE PIPE CULVERT SHALL BE PLACED IN THE CONCRETE END SECTION SO THAT THE FLOW LINES ARE FLUSH. THE JOINT SHALL BE COMPLETELY FILLED WITH MORTAR.
 - TO CHANGE THE FILL SLOPE TO THE SLOPE OF THE END SECTION, USE A TRANSITION SLOPE OF APPROXIMATELY 10' IN LENGTH TO PROVIDE A PLEASING APPEARANCE.
 - VARIATIONS IN DIMENSIONS - THE THICKNESS OF CONCRETE, THE POSITION OF STEEL, AND THE INTERNAL DIAMETER OF THE PIPE SHALL CONFORM WITH THE VARIATIONS IN DIMENSIONS AS PROVIDED IN THE SPECIFICATIONS FOR REINFORCED CONCRETE CULVERT, STORM DRAINS, AND SEWER PIPE, A.S.T.M. DESIGNATION C76.
 - PLACE CONCRETE FOOTING WHEN CULVERT GRADE IS 4% OR MORE, OR WHEN SPECIFIED ON THE ROAD PLANS.
 - OUTFALL LABEL TO BE USED ONLY WHERE STORMWATER WILL DISCHARGE DIRECTLY TO THE WATERS OF THE STATE.

PRECAST CONCRETE END SECTION FOR PIPE CULVERT

NOTES:

- REFER TO DRAWING NUMBER D-04-08-135 FOR THE LIMITS OF CHANNEL ARMORING WITHIN THE O'BRIEN DRAIN.
- THE ARTICULATED CONCRETE MATTRESS SHALL CONFORM TO THE REQUIREMENTS OF SECTION 02300.
- GEOTEXTILE FILTER FABRICS SHALL CONFORM TO THE REQUIREMENTS OF SECTION 02275.
- THE SUBGRADE AND BEDDING SHALL BE INSPECTED AND APPROVED BY AN ENGINEER PRIOR TO INSTALLATION OF THE GEOTEXTILE FABRIC.
- NO MECHANICAL EQUIPMENT SHALL BE DRIVEN DIRECTLY ON TOP OF THE FABRIC.
- THE FABRIC SHALL BE STORED IN SUCH A WAY THAT IT IS PROTECTED FROM PROLONGED EXPOSURE TO ULTRAVIOLET RADIATION.
- NO FABRIC SHALL BE COVERED UNTIL INSPECTED AND APPROVED BY THE ENGINEER.
- ALL ARTICULATED CONCRETE MATTRESS SHALL BE PRE-MANUFACTURED AS AN ASSEMBLY OF CONCRETE BLOCKS BOUND INTO MATS BY THE USE OF RETENTION CABLES.
- ALL CONCRETE MAT UNITS SHALL BE SOUND AND FREE OF DEFECTS THAT WOULD INTERFERE WITH THE PROPER PLACING OF THE UNIT OR IMPAIR THE STRENGTH OR PERMANENCE OF THE CONSTRUCTION.

Keith Sirois**SPALDING DEDECKER****905 E South Blvd****Rochester Hills****MI****48307**Dear **Keith Sirois**

This letter is in response to your request for Buckeye Partners involvement with the proposed construction of the above-mentioned project.

Upon review of your request it has been determined that Buckeye Partners ("Buckeye") does have pipeline facilities within the limits of the proposed project. A drawing depicting the approximate location of the pipeline facility has been included for your reference.

Additionally, a copy of Buckeye's Right of Way Use Restrictions Specification (ROWURS) has been included for your review. The ROWURS provides specific guidance on various property development activities useful for your plan design and also includes Buckeye's Application for Design Plan Submission and Encroachment Review. Before any preliminary field work or construction begins in the vicinity of Buckeye's pipeline, a determination of the exact location and elevation of the pipeline must be made. To coordinate this procedure, please contact our 811 Damage Prevention Team at 610-904-4940.

Once the exact pipeline location and elevation has been added to your drawings/plans along with a profile sheet for all proposed encroachments, submit the drawings/plans, Application for Design Plan Submission and Encroachment Review, and the appropriate review fee to Buckeye's Right of Way Department for review. Buckeye's encroachment review team will determine to what extent, if any, the pipeline right-of-way will be affected by the proposed construction.

Should you have any questions or need any additional information, please do not hesitate to contact me at (610)-904-4475 or you can email me at tmccclernon@buckeye.com.

Please mail all correspondence to:

Buckeye Partners
6161 Hamilton Blvd
Allentown, PA 18106

ATTN: Dave Jones / Senior ROW Specialist

You may e-mail plans to: encroachmentreviews@buckeye.com.

You can contact Dave at **610-904-4409**, should you require anything further.

Sincerely,

Traci L McClernon
811 Damage Prevention Lead

22-OCT-2021

Revised 09-30-2015 by Data Integrity/Mapping Tech
File: PIng_Des_Bdry_w_Emails_Sept_2015.mxd

Please note:

All documentation to be reviewed at the Utility Coordination Meeting must be received at least 10 business days prior to the meeting date: Send all information to the Regional Planning Office where your project is located. **See Planning and Design Service Area Map.**

For all future correspondence on this request, please contact the Regional Planning Office for your project.

To help facilitate timely electric utility coordination, please note the following:

Provide conflict list and associated drawings.

Specifically identify conflicts and provide locations of conflicts.

Poles and/or wire conflicts.

Street lighting posts and/or underground cable.

Underground facilities, i.e. cable, conduit, manholes and ground mounted equipment.

Send documents to the Regional Planning Office.

Documents must be received no less than 10 days before the Utility Coordination Meeting.

Requesting Company / Owner Agency to conduct Utility Coordination Meeting

The purpose of this meeting is to confirm design conflicts and discuss design options and/or relocation options.

Meeting should occur as soon as possible, but after the following have been completed.

Utilities have been plotted on Requesting Company / Owner Agency's design documents.

Conflicts have been identified by Requesting Company / Owner Agency.

Conflict list has been created by Requesting Company / Owner Agency.

Requesting Company / Owner Agency to conduct Pre-Construction Meeting

The purpose of this meeting is to confirm or coordinate the resolution of conflicts/relocations identified at the Utility Coordination Meeting.

Conflict information must be communicated prior to the Utility Coordination Meeting. Failure to do so will likely prevent DTE from meeting the project's utility relocation time line.

Things to Remember

Designers should be instructed to make every effort to avoid utility relocations.

Underground relocations can take up to 18 months or longer.

Overhead relocations can take 6 months or longer depending on the facilities involved.

SURVEYOR'S COMMENTS

1. THIS TOPOGRAPHICAL MAP IS BASED UPON A FIELD SURVEY PERFORMED BY SPALDING DEDECKER INC. DURING DECEMBER OF 2022 AND JANUARY 2023.
2. SPALDING DEDECKER HAS BASED THE PROPERTY LINES AND RIGHT OF WAY LINES UPON A COMBINATION OF CITY OF DETROIT TAX (LEGAL) DESCRIPTIONS AVAILABLE ON THE CITY "BS&A ON-LINE" WEBSITE, FOUND FIELD MONUMENTATION AND OCCUPATION.
3. THIS SURVEY HAS BEEN PREPARED WITHOUT THE BENEFIT OF A CURRENT TITLE SEARCH THAT WOULD IDENTIFY ANY RECORDED EASEMENTS THAT ENCUMBER OR BENEFIT THIS PROPERTY. THEREFORE, THIS PROPERTY MAY BE SUBJECT TO EASEMENTS, RIGHT-OF-WAY TAKINGS AND RESTRICTIVE COVENANTS THAT ARE NOT SHOWN.
4. THE BASIS OF BEARINGS IS THE STATE PLANE GRID.
5. THE COORDINATE SYSTEM FOR THIS SURVEY IS THE STATE PLANE COORDINATE SYSTEM, MICHIGAN SOUTH ZONE (2113), BASED ON NAD83 (NSRS2011). UNITS ARE INTERNATIONAL FEET. COORDINATES WERE ESTABLISHED USING A DATA LINK TO THE MDOOT CONTINUOUSLY OPERATING REFERENCE STATIONS (CORS).
6. THE VERTICAL DATUM OF THIS SURVEY IS BASED UPON THE LOCAL CITY OF DETROIT DATUM BASED ON THE MASTER BENCHMARK LISTED. THE CONVERSION TO NAVD88 IS +479.215 WHICH AGREES WITH THE COMPUTED VALUE FOR THIS AREA. THE PRIOR SITE PLAN FOR THE SITE INDICATES A PROPOSED FINISH FLOOR OF 140.00' FOR THE BUILDING. WE MEASURED THE DOOR LEASE ELEVATION AT VARIOUS OPENINGS WHICH VARY FROM 139.84' TO 140.01' AND VALIDATE THE PROPER ESTABLISHMENT OF THE PRIOR PLAN DATUM.
7. THE UTILITY INFORMATION SHOWN ON THIS SURVEY IS BASED UPON A COMBINATION OF RECORD INFORMATION AND FIELD MEASUREMENTS. A MISS DIG DESIGN TICKET NUMBER OF 2022102503675 HAS BEEN REFERENCED TO THIS PROJECT AND A UTILITY PROVIDER CHART IS SHOWN ON THIS DRAWING. THERE ARE NO ASSURANCES THAT ALL PROVIDERS HAVE RESPONDED AND THE SURVEYOR DOES NOT GUARANTEE THAT ALL UNDERGROUND UTILITIES ARE SHOWN AND/OR POSITIONED PROPERLY ON THIS DRAWING DUE TO AMBIGUOUS PLANS AND RECORDS PROVIDED TO US. THE INFORMATION SHOWN ON THIS DRAWING IS INTENDED TO BE USED AS A GUIDE FOR POSSIBLE UNDERGROUND UTILITY CONFLICTS. IT IS THE RESPONSIBILITY OF OTHERS TO RESOLVE THE ACTUAL LOCATION OF ANY UNDERGROUND UTILITY THROUGH THE MISS DIG FIELD VERIFICATION SYSTEM PRIOR TO ANY SITE EXCAVATION. CALL 811 OR 800-482-7171.
9. BUILDING FACES AND EXTERIOR COLUMNS HAVE BEEN LOCATED TO A PRECISION ACCEPTABLE FOR TOPOGRAPHICAL MAPPING. IF THEY EXIST, DECORATIVE ARCHITECTURAL BRICK AND STONE FEATURES ARE TYPICALLY NOT INCLUDED. ADDITIONAL HIGH-PRECISION DETAILED MEASUREMENTS OF BOTH EXTERIOR WALL LINES AND INTERIOR COLUMNS ARE SUGGESTED FOR ANY AREAS WHERE BUILDING ADDITIONS ARE PLANNED.
10. THE ALLEY ADJACENT TO THE LOTS HAS BEEN VACATED BASED ON DOCUMENTATION WE RECEIVED IN JANUARY, 2023. THE SURVEY HAS BEEN UPDATED ACCORDINGLY TO REFLECT THIS.
11. THE 10' AND 20' ALLEYS THAT ABOUT LOTS 21-23 ARE COVERED WITH GRASS THAT IS BEING MOVED. IT IS POSSIBLE THAT THERE ARE STILL CONCRETE, ASPHALT, OR BRICK STREETS BURIED BELOW THE CURRENT GRASS SURFACE.

RE: Report on Geotechnical Investigation
Great Lakes Water Authority (GLWA)
Design Services for Combined Sewer Outfall (CSO) Improvements Project
GLWA Leib CSO Facility - Contract Number 2101475
Detroit, Michigan

Dear Mr. Khraizat:

We have completed the Report on Geotechnical Investigation for the GLWA Leib CSO Facility Project in the City of Detroit, Michigan. This report presents the results of our observations and results of the geotechnical.

The soil samples collected during our field investigation will be retained in our laboratory for 90 days from the date of the final report, at which time these samples will be discarded unless otherwise directed by you.

It was a pleasure working with you on this project. If you have any questions regarding this report, please do not hesitate to contact us 313-963-2721.

Sincerely,
Somat Engineering, Inc.

REPORT SUMMARY

A general summary of the report conclusions is provided below:

1. The field exploration program consisted of performing a total of 2 soil borings for the GLWA Leib CSO Facility Project in Detroit, Michigan. The borings extended to a depth of 10 feet below existing grades.
2. Generalized soil profile: fill soils was encountered in boring SB-02 and extended to a depth of 1.3 feet below existing grades.
3. The long-term groundwater table is estimated to be situated at about 7 feet (EL. 133.1 feet) below existing grades. Perched groundwater trapped in the granular fill soils within close proximity of any excavations should also be expected.
4. We recommend undercutting the upper topsoil and underlying granular fill soils to a minimum depth of about 1.5 feet below existing grades and replacing with engineered granular fill soils (such as MDOT 21AA or Class II sand), new base course, and pavement. Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted new engineered fill subgrade soils prepared as noted in this report; should be adequate to support the proposed HS-20 traffic loading for the access drive.

The summary presented above is general in nature and should not be considered apart from the entire text of the report with all the qualifications and considerations mentioned therein. Details of our findings and recommendations are discussed in the following sections and in the appendices of this report.

**REPORT ON GEOTECHNICAL INVESTIGATION
GREAT LAKES WATER AUTHORITY (GLWA)
GLWA LEIB CSO FACILITY
DETROIT, MICHIGAN**

1.0 INTRODUCTION

1.1 GENERAL

Upon authorization from CDM Smith, Somat Engineering, Inc. (Somat) has completed the geotechnical investigation for the development of the Great Lakes Water Authority (GLWA) Design Services for Combined Sewer Outfall (CSO) Improvements Project at the Leib CSO Facility in the City of Detroit, Wayne County, Michigan.

Somat was retained by CDM Smith to perform a pre-design geotechnical investigation for the referenced project within the project limits. The geotechnical investigation was performed in general accordance with Somat Proposal No. P210314B dated January 12, 2022. The results of the investigation will be used to support the design of the project and development of construction specifications.

1.2 PROJECT INFORMATION

The overall project includes design services required to implement a series of improvements at the Leib CSO Screening and Disinfection (SDF) facility located at 2200 Mt. Elliott, Detroit, Michigan. The site improvements include constructing a new alternate access road shall be about 176 feet long and 24 feet wide, and will require minimal reconfiguration of the existing parking lot.

The following sections of this report provide a description of our field investigation, the results of the field and laboratory tests, the logs of auger probes, our interpretation of subsoil and groundwater conditions, recommendations related to the proposed construction.

2.0 SUBSURFACE INVESTIGATION

2.1 FIELD EXPLORATION

The field exploration program consisted of performing a total of two (2) soil borings. Borings SB-01 and SB-02 were performed along the grass covered parcel on the east side of the Leib gated facility. The borings extended to a depth of 10 feet below existing grades.

The soil borings were drilled using Geoprobe 3126GT drill rig. The soil borings were drilled by advancing hollow stem augers to the termination depths of the soil borings. Upon completion, all the boreholes were backfilled with soil cuttings to the surface. The soil boring logs are presented as logs of test borings in Appendix B. Soil boring coordinates and the ground surface elevations (included in the soil boring logs) were provided by the Project Surveyor based on City of Detroit Datum.

2.2 STANDARD PENETRATION TEST

Soil samples collected during the field portion of the subsoil exploration were labeled with the soil boring designation and a unique sample number. Soil samples were obtained from the soil borings by Standard Penetration Tests (SPT) in accordance with ASTM D1586 procedures, whereby a conventional 2-inch O.D. split-spoon sampler is driven into the soil with a 140-pound hammer repeatedly dropped through a free-fall distance of 30 inches. The sampler is generally driven three successive 6-inch increments, with the blows for each 6-inch increment being recorded. The number of blows required to advance the sampler through 12 inches after an initial penetration of 6 inches is termed the Standard Penetration Test resistance (N-value) and is presented graphically on the individual Logs of Test Borings. As added information, the number of blows for each 6-inch increment is also presented on the boring logs.

The N-values reported on the Logs of Test Borings are the direct blow counts from the field and are uncorrected. The efficiency of each specific hammer is dependent on many factors, including type (auto vs. manual), material quality, regularity of maintenance, drill rig mechanics, etc., and can change with time. As such, SPT hammers on each drill rig are required to be calibrated. Certificates are provided to us indicating each hammer's measured energy transfer

ratio. For this project, the geotechnical driller (DLZ American Drilling) used a Geoprobe 3126GT drill rig (serial number: 52110001). Based on the current certificate for this drill rig, the energy transfer ratio for the SPT hammer is 101.3%.

2.3 SAMPLING

Soil boring samples were recovered using split-spoon sampling procedures in accordance with ASTM Standard D1586 (“Standard Method for Penetration Tests and Split Barrel Sampling of Soils”). In general, the samples were obtained continuously to a depth of 5 feet and every 2.5 feet intervals to the termination depth of the borings. The samples were sealed in glass jars in the field to protect the soil and maintain the soil’s natural moisture content.

2.4 GROUNDWATER LEVEL OBSERVATION PROCEDURES

Whenever possible, groundwater level observations were made during the drilling operations and are shown on the individual Logs of Test Borings. During drilling, the depth at which free water was observed, where drill cuttings became saturated or where saturated samples were collected, was indicated as the groundwater level during drilling. In granular, pervious soils, the indicated water levels are considered relatively reliable when solid or hollow-stem augers are used for drilling. However, in cohesive soils, groundwater observations are not necessarily indicative of the static water table due to the low permeability rates of the soils, and due to the sealing off of natural paths of groundwater flow during drilling operations.

It should be noted that seasonal variations and recent precipitation conditions may influence the level of the groundwater table significantly. Groundwater observation wells are generally used if precise groundwater table information is needed, however the installation of groundwater monitoring wells was not included in the scope of the investigation. Therefore, the discussion and recommendations provided within the report are based on our knowledge of the soil and groundwater conditions in this area, as well as the reported design water levels of water bodies located at the bridge locations, which should provide for a reasonable approximation of the groundwater level.

2.5 GEOTECHNICAL LABORATORY TESTING

All soil samples were classified in accordance with the Unified Soil Classification System (USCS). Cohesive soil samples were subjected to laboratory tests consisting of moisture content determinations, and hand penetrometer tests. Loss-on-ignition (LOI) tests are performed on any samples that appear to contain significant organic content.

The results of the soil classifications and the laboratory tests are included on the respective logs in Appendix B. All laboratory tests were performed in accordance with their applicable ASTM procedures.

2.6 LIMITATIONS

The scope of our services was strictly geotechnical and did not include environmental investigation. Our scope of services did not include investigation for the presence or absence of wetlands or hazardous or toxic materials in the soil, surface water, groundwater, or air, on, below or around this site.

Somat has made no observations or recommendations with regard to the presence or absence of mold or other biological contaminants (such as spores, fungi, bacteria, viruses, and the byproducts of such organisms), now or in the future, on this site or within or on any structures to be constructed on this site. Any consideration with regard to the presence of mold, or the possibility of mold growth in or on the structure to be constructed on this site are not within our scope of services on this project.

Some soils have been identified on the Logs of Test Borings as “fill” or “possible fill” if a soil deposit is suspected to have been placed by human activity, versus having been deposited by natural means. These designations were based on our professional engineering judgment considering factors such as our visual classification, the presence of foreign materials (i.e., bricks, concrete, plastic, etc.), and/or site topography, among many other possibilities. As such, the “fill” or “possible fill” descriptions should be considered as secondary information to the standardized soil classification. Due to the large variation of types of fill, methods of fill

placement, potential changes of historical use of the site, and soil sample size, it is difficult to discern whether the subject soil sample is native to this site, or fill material based on visual classification alone. As such, the designation of “fill” may not be reliable and hence should be considered as informational only. Conversely, where a soil is not designated as “fill” on the boring logs, it does not necessarily mean it is not a fill soil, only that there were no apparent observations indicating a fill material. Therefore, we cannot guarantee that our description of “fill” soils is accurate, or that we have identified all types of fill material encountered with our sampling on the site.

3.0 SUBSURFACE CONDITIONS

3.1 SOIL CONDITIONS

Soil conditions encountered at the boring locations have been evaluated and presented in the form of logs of auger probes. The logs of auger probes include approximate soil stratification with detailed soil descriptions and selected physical properties for each stratum encountered in the auger probes. In addition to the observed subsoil stratigraphy, the auger logs present information relating to sample data, groundwater level conditions observed in the probing, personnel involved, and other pertinent data. For information, and to aid in understanding the data as presented on the auger logs, General Notes defining nomenclature used in soil descriptions are presented immediately following the Logs of Test Borings. It should be noted that the Logs of Test Borings included with this report have been prepared on the basis of laboratory classifications and testing as well as field logs of the soils encountered.

A generalized description of the soils and pavement encountered in the six (6) auger probes beginning at the existing ground surface and proceeding downward, is provided below:

Stratum 1: Surface Material:

- **Topsoil:** Clayey topsoil was encountered at the surface of SB-01 and SB-02 and had a thickness of 6 inches.

Stratum 2: Fill Soils:

- **Granular Fill:** Granular fill soils consisting of sand with silt was encountered below the topsoil in boring SB-02 and extended to a depth of 1.3 below existing grades. The apparent density of the fill soils was dense.

Stratum 3: Native Cohesive Soils

- Native sandy lean clay was encountered below the topsoil or fill soils in both borings and extended to a depth of 2 to 3.5 feet below existing grades. The consistency of the clay was hard and had a moisture content ranging between 9 and 14%.

Stratum 4: Native Granular Soils

- Native granular soils consisting of sand and silty sand were encountered below the native clays in both borings and extended to the termination depth of 10 feet in boring SB-01 and to a depth of 8 feet in boring SB-02. The apparent density of the native granular soils ranged between medium dense and very dense.

Stratum 5: Native Cohesive Soils

- Native lean clay was encountered below the native granular soils in boring SB-02 and extended to the explored depth of 10 feet below existing grades. The consistency of the clay was very stiff and had a moisture content of 15%.

The logs of soil borings are presented in Appendix B and the soil boring location diagram is presented in Appendix A. It is emphasized that the stratification lines shown on the logs are approximate indications of change from one soil type to another at the locations of the boreholes. The actual transition from one stratum to the next may be gradual and may vary within the area represented by the test boring.

3.2 GROUNDWATER LEVEL OBSERVATIONS

Groundwater was not encountered in boring SB-01. Groundwater was encountered at a depth of 7 feet during drilling and 8.5 feet after completion of drilling in boring SB-02.

A lack of groundwater in some of the auger holes, does not necessarily mean there is no groundwater in this area, due to the sealing off of natural flow paths during the drilling process. Oftentimes, a change in color from brown to gray in cohesive soils is a good indication of the long-

term groundwater level (indicating oxidation). As such the long-term groundwater table is estimated to be situated at about 7 feet below existing grades (EL. 133.1 feet).

Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected.

It should be noted that the elevation of the long-term groundwater table is likely to vary throughout the year depending on the amount of precipitation, runoff, evaporation, and percolation in the area, as well as on the water level in any surface water bodies in the vicinity affecting the groundwater flow pattern.

4.0 GEOTECHNICAL RECOMMENDATIONS

4.1 PROPOSED ACCESS DRIVE

The project includes the construction of a new paved alternate access road that is about 176 feet long and 24 feet wide. The proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

4.1.1 Subgrade Preparation and Groundwater Control Recommendations

Based on the soil borings, the subgrade soils consist of existing granular fill soils over native hard lean clay. We do not recommend constructing new pavement on undocumented fill soils. As such we recommend undercutting the upper topsoil and underlying granular fill soil to a minimum depth of about 1.5 feet below existing grades and replacing with engineered granular fill soils (similar in gradation to MDOT 21AA or Class II sand), new base course, and Portland cement concrete pavement.

Once a rough subgrade has been achieved, the exposed pavement subgrade along the entire sections of access drive to be constructed should be visually checked for the presence of debris, organic matter, and other unsuitable material.

If unsuitable or highly organic subgrade soils (organic contents greater than 4%) are encountered during construction, the material should be assessed by the on-site geotechnical engineer to determine the depth and extent of the material and whether it should be fully undercut.

All of the pavement subgrade areas should be thoroughly proof rolled before placement of the new base course and pavement. The purpose of the proof rolling is to locate overly loose or soft areas as well as to uniformly compact the subgrade surface. In granular soils, proof rolling should be performed with a heavy (minimum 30 ton) self-propelled vibratory roller. Loose or soft areas revealed during compaction or during the proof rolling should either be suitably compacted and aerated if necessary. Any areas that exhibit excessive pumping or yielding should be stabilized, scarified, and re-compacted, if weather conditions permit, or by the removal of the yielding soils and their replacement with engineered fill.

The pavement subgrade will need to be compacted to a minimum of 95 percent of the maximum dry density as determined in accordance with ASTM D-1557 (Modified Proctor). It may be necessary in some areas to undercut unsuitable soils and replace them with a stabilization layer of engineered fill.

The long-term groundwater table is estimated to be situated at a depth of about 7 feet below existing grades (EL. 133.1 feet). Perched groundwater within the granular and fill soils above the less permeable clay layers should be expected and the Contractor should be prepared to handle. Water trapped in existing utility trenches in the area, which are often sand backfill within the native clay soils, should be expected. We do not expect the excavations required to construct the access drive would extend below the estimated long-term groundwater. As such, we believe the groundwater should be adequately controlled using standard sump pits and pumping methods.

4.1.2 Drainage Considerations

The effects of frost heave are anticipated to be more significant in areas where water is not allowed to drain freely either due to subsoil conditions, site grades, or other factors. We recommend including a new drainage system within the new base course to drain water away from the pavement. The pavement and subgrade will need to be positively graded towards these drainage features or away from the center of the roadway to allow for gravity flow of groundwater.

For all new pavements, final pavement elevations should be designed to provide positive surface drainage. The minimum surface slope of 2 percent is recommended. The pavement surface should be smooth, free of roller marks or depressions, and should not contain any irregularities which would pond or impede water flow

4.1.3 Pavement Design Recommendations

4.1.3.1 Subgrade Design Values

We anticipate the subgrade soils for the proposed pavement construction will consist of existing fill soils. The recommended subgrade resilient modulus (M_R) and vertical subgrade reaction (K_v) provided below assumes the soil conditions encountered in the auger probes are representative of the soil conditions within the proposed pavement construction areas. This also assumes the recommended earthwork operations will have been incorporated into the project specifications and that the subgrade soils will have been compacted. If during construction, the subgrade is found to vary from the expected soil conditions, we should be contacted so we may re-evaluate our soil design parameters.

For Portland cement concrete pavement design, based on our experience with similar soil conditions and the results of the in-situ SPT tests, we recommend the following coefficients of subgrade reaction (K_v), subgrade resilient moduli (M_R), and CBR's be used as representation for the conditions of the soils at the new base course and subgrade levels compacted to project specifications.

Table 4.1.3.1 Recommended Pavement Subgrade Design Parameters

Soil Type	Coefficient of Vertical Subgrade Reaction, (K_v)	Subgrade Resilient Moduli (M_R)	CBR
Existing Native Clay Soils	85 pci	6,000 psi	4
New Engineered Sand Fill (MDOT Class II)	235 pci	22,500 psi	15
New Engineered Aggregate Base (MDOT 21AA)	340 pci	37,500 psi	25

Other factors should also be considered in the final pavement design, in addition to the subgrade modulus values. These factors may include, but are not limited to, adequate subgrade preparation, adequate placement of engineered fill and pavement layers, and surface and subsurface drainage.

4.1.3.2 Pavement Section Design Recommendations

As we understand, the proposed pavement section will be Portland cement concrete and gutter and the thickness of the pavement is anticipated to consist of 9-inch-thick reinforced concrete pavement over a minimum of 8-inch-thick aggregate base in conformance to MDOT 21AA gradation. The pavement will be designed to support HS-20 loading.

We performed pavement analysis utilizing the AASHTO 1993 Guide for Design of Pavement Structures and the associated design charts and nomographs. The following list summarizes our input parameters and assumptions based on AASHTO guidelines and our observations:

Pavement Design Life	20 years (7 days per week)
Loading	HS-20 (8,000 lb/ front axle and two 32,000 lb/ rear axles (Given)
Load Equivalent Factor (LEF)	2.985 (calculated based on HS-20 loading using AASHTO LEF tables for terminal serviceability of 2.5)
Maximum Average Daily Traffic (ADT)	185 vehicles per day with HS-20 loading criteria (Back calculated)
Maximum Design ESAL's:	4,000,000 ESAL (Back calculated)
Percent Trucks:	100 %

Reliability:	90 % (Arterial road)
Standard Deviation:	0.35 (Rigid pavement)
Drainage Coefficient:	1.0
Initial Serviceability:	4.5 (Rigid pavement)
Terminal Serviceability:	2.5 (Major collectors)
Growth Rate	3%
Load Transfer Coefficient	2.7 (Dowel and mesh)
Concrete Elastic Modulus	6,000,000 psi (Assumed)
Effective Modulus of Subgrade Reaction of new base course (MDOT 21AA)	340 pci (CBR =25)
Effective Modulus of Subgrade Reaction of clay subgrade	85 pci (CBR =4)
Mean Concrete Modulus of Rapture	650 psi

Based on our analysis we checked that the proposed pavement section design consisting of 9 inches of Portland cement concrete over a minimum of 8 inches of new aggregate base course that is similar in gradation to MDOT 21AA over the compacted existing granular fill soils prepared as noted in this report; should be adequate to support the proposed traffic loading for the access drive.

5.0 GENERAL QUALIFICATIONS

All construction activities should be monitored under the direction of a qualified Geotechnical Engineer to verify conditions as interpreted in this report. This report and the attached Logs of Soil Borings are instruments of service, which have been prepared in accordance with generally accepted soil and foundation engineering practices. We make no other warranties either expressed or implied as to the professional advice included in this report.

The contents of this report have been selected in order to aid in the evaluation of expected subsoil properties to assist the Engineer in the design of this project. In the event that any changes are made in the geotechnical aspects of this project, however slight, the conclusions and recommendations contained in this report shall not be considered valid unless the changes are reviewed, and the conclusions of this report are modified in writing by our office.

Since the information obtained from auger probes is specific to the exact test locations, soil and water information could be different from those occurring at other locations of the site. This report does not reflect variations which may occur between the test holes. The nature and extent of these variations may not become evident until the time of construction. If significant variations then become evident, it may be necessary for us to re-evaluate the recommendations provided in this report.

This report and the associated soil logs should be made available to bidders prior to submitting their proposals and to the successful Contractor and subcontractors for their information only, and to supply them with facts relative to the subsurface investigation, laboratory tests, etc.

The discussions and recommendations submitted in this report are based on the soil information contained in the Logs of Soil Borings and test results appended to this report. We expect that the logs of auger probes, test results, and the soil profiles included in this report along with our discussions and conclusions will assist you in designing the proposed pavement. Please refer to Appendix C for important information about this geotechnical investigation report. If you have any questions regarding this report, please contact us.

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2488 (Modified)

DRILLING & SAMPLING SYMBOLS:

SS:	Split Spoon – 1 3/8" I.D., 2" O.D. (standard)	BS:	Bulk Sample	RC:	Rock Core with diamond bit, NX size, (unless otherwise noted)
S:	Split Spoon – non-standard size, as noted	HSA:	Hollow Stem Auger		
ST:	Thin-Walled Tube – 3" O.D., (unless otherwise noted)	DP:	Direct Push	RB:	Rock Bit/Roller Bit
LS:	Liner Sample	PS:	Piston Sample	WR:	Wash Rotary
PA:	Power Auger	PT:	Pitcher Sample	NR:	No Recovery
HA:	Hand Auger	WS:	Wash Sample	VS:	Vane Shear Test
AU:	Auger Sample			ER:	Hammer Energy Ratio

Standard Penetration Test Resistance, N-Value: Sum of 2nd and 3rd 6-inch increments, in blows per foot of a 140-pound hammer falling 30 inches and driving an 18-inch to 30-inch long, 2-inch OD split spoon.

WATER LEVEL MEASUREMENT:

Water levels indicated on the boring logs are the levels measured in the borings at the times indicated. In pervious soils, the indicated levels may reflect the location of a groundwater table. In low permeability soils (clays and silts), the accurate determination of groundwater levels may not be possible with only short-term observations. Groundwater levels at times and locations other than when and where individual borings were performed could vary.

DESCRIPTIVE SOIL CLASSIFICATION:

Soil classification is based on the Unified Soil Classification (USC) System and ASTM Standards D-2487 and D-2488. Coarse-grained soils have more than 50% of their dry weight retained on a #200 sieve; they are described as: gravel or sand. Fine-grained soils have less than 50% of their dry weight retained on a #200 sieve; they are generally described as: clays, if they are plastic, and silts, if they are slightly plastic or non-plastic. Major constituents may be added as modifiers and minor constituents may be added according to the relative proportions based on grain size. In addition to gradation, coarse-grained soils are defined on the basis of their apparent in-place density and fine-grained soils on the basis of their apparent in-place density (silty soils) or consistency (clayey soils).

CONSISTENCIES OF COHESIVE SOILS:

The pocket penetrometer, pocket torvane, and in-situ vane shear tests are converted into an estimated unconfined compressive strength, in pounds per square feet (psf), for presentation on the logs. The unconfined compressive strength is estimated to be about two time the shear strength.

DESCRIPTORS OF MINOR CONSTITUENTS

Primary Constituent	Fine-Grained (Silt & Clay)	Coarse-Grained (Sand & Gravel)	
Descriptor of Other Constituents	Relative Portion of Coarse Grained Soils as a % of Dry Weight	Relative Portion of Fine Grained Soils as a % of Dry Weight	Relative Portion of Coarse Grained Soils as a % of Dry Weight
Trace	<5%	<5%	<5%
Few	≥5% - <15%	N/A	≥5% - <15%
With	≥15% - <30%	≥5% - 12%	≥15%
Modifier	≥30%	>12%	N/A

FINE-GRAINED SOILS

Unconfined Compressive Strength Q_u , psf	Consistency	N-Value	Apparent Density
< 500	Very Soft	0 – 4	Very Loose
500 - <1,000	Soft	5 – 9	Loose
1,000 - <2,000	Medium	10 – 29	Medium Dense
2,000 - <4,000	Stiff	30 – 49	Dense
4,000 - <8,000	Very Stiff	50 – 80	Very Dense
≥ 8,000	Hard	>80	Extremely Dense

COARSE-GRAINED SOILS

DEFINITIONS OF STRUCTURAL AND DEPOSITIONAL FEATURES

Term	Definition
Parting	≤ 1/16 inch (1.6 mm) thick
Seam	> 1/16 inch (1.6 mm) → 1/2 inch (12.7 mm) thick
Layer	> 1/2 inch (12.7 mm) to ≤ 12 inches (305 mm) thick
Pocket	Small, erratic deposits of limited lateral extent
Lens	Lenticular deposit
Lensed	Inclusion of small pockets of different soils, such as small lenses of sand scattered through a mass of clay
Varved	Alternating partings or seams (1 mm – 12 mm) of silt and/or clay and sometimes fine sand
Stratified	Alternating layers of varying material or color with layers ≥ 6 mm thick
Laminated	Alternating layers of varying material or color with layers < 6 mm thick
Fissured	Contains shears or separations along planes of weakness
Slickensided	Shear planes appear polished or glossy, sometimes striated
Blocky	Cohesive soil that can be broken down into small angular lumps which resist further breakdown
Homogeneous	Same color and appearance throughout
Occasional	One or less per foot (305 mm) of thickness
Frequent	More than one per foot (305 mm) of thickness
Interbedded	Applied to strata of soil lying between or alternating with other strata of a different nature

DEFINITIONS OF PAVEMENT CONDITION

Condition	Description
Good	ACC Very slight or no raveling, surface shows some traffic wear. Longitudinal cracks and transverse cracks (open 1/4 inch). No patching or very few patches in excellent condition.
	PCC Moderate scaling in several locations. A few isolated surface spalls. Shallow reinforcement causing cracks. Several corner cracks, tight or well sealed. Open (1/4 inch wide) longitudinal or transverse joints.
Fair	ACC Severe surface raveling. Multiple longitudinal and transverse cracking with slight raveling. Longitudinal cracking in wheel path. Block cracking (over 50% of surface). Patching in fair condition. Slight rutting or distortions (1/2 inch deep or less).
	PCC Severe polishing, scaling, map cracking, or spalling over 50% of the area. Joints and cracks show moderate to severe spalling. Pumping and faulting of joints (1/2 inch with fair ride). Several slabs have multiple transverse or meander cracks with moderate spalling.
Poor	ACC Alligator cracking (over 25% of surface). Severe distortions (over 2 inches deep) Extensive patching in poor condition. Potholes.
	PCC Extensive slab cracking, severely spalled and patched. Joints failed. Patching in very poor condition. Severe and extensive settlement or frost heaves.

GRAIN SIZE TERMINOLOGY

Major Component of Sample	Size Range
Boulders	≥ 12" (300 mm)
Cobbles	< 12" - 3" (300 mm – 75 mm)
Gravel - Coarse	< 3" - 3/4" (75 mm – 19 mm)
Gravel - Fine	< 3/4" - #4 (19 mm – 4.75 mm)
Sand - Coarse	< #4 - #10 (4.75 mm – 2 mm)
Sand - Medium	< #10 - #40 (2 mm - 0.425 mm)
Sand - Fine	< #40 - #200 (0.425 mm - 0.074 mm)
Silt	< 0.074 mm - 0.005 mm
Clay	< 0.005 mm

GENERAL NOTES

Unified Soil Classification System (USCS) ASTM D2487

Criteria for Assigning Group Symbols and Group Names Using Laboratory Tests ^A				Soil Classification			
				Group Symbol	Group Name <i>B</i>		
COARSE-GRAINED More than 50 % retained on No. 200 sieve	Gravels (More than 50 % of coarse fraction retained on No. 4 sieve)	Clean Gravels	$Cu \geq 4$ and $1 \leq Cc \leq 3^D$	GW	Well-graded gravel ^E		
		(Less than 5% fines ^C)	$Cu < 4$ and/or $[Cc < 1$ or $Cc > 3]^D$	GP	Poorly graded gravel ^E		
		Gravels with Fines	Fines classify as ML or MH	GM	Silty gravel ^{E,F,G}		
		(More than 12 % fines ^C)	Fines classify as CL or CH	GC	Clayey gravel ^{E,F,G}		
	Sands (50 % or more of coarse fraction passes No. 4 sieve)	Clean Sands	$Cu \geq 6$ and $1 \leq Cc \leq 3^D$	SW	Well-graded sand ^F		
		(Less than 5 % fines ^H)	$Cu < 6$ and/or $[Cc < 1$ or $Cc > 3]^D$	SP	Poorly graded sand ^F		
		Sands with Fines	Fines classify as ML or MH	SM	Silty sand ^{F,G,I}		
		(More than 12 % fines ^H)	Fines classify as CL or CH	SC	Clayey sand ^{F,G,I}		
FINE-GRAINED SOILS 50 % or more passes the No. 200 sieve	Silts and Clays Liquid limit less than 50	inorganic	$PI > 7$ and plots on or above "A" line ^J	CL	Lean clay ^{K,L,M}		
			$PI < 4$ or plots below "A" line ^J	ML	Silt ^{K,L,M}		
		organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OL	Organic clay ^{K,L,M,N} Organic silt ^{K,L,M,O}		
			inorganic	PI plots on or above "A" line	CH	Fat clay ^{K,L,M}	
	Silts and Clays Liquid limit more than 50	inorganic	PI plots below "A" line	MH	Elastic silt ^{K,L,M}		
			organic	(Liquid Limit - oven dried) / (Liquid Limit - not dried) < 0.75	OH	Organic clay ^{K,L,M,P} Organic silt ^{K,L,M,Q}	
		HIGHLY ORGANIC SOILS Primarily organic matter, dark in color, and organic odor				Pt	Peat
		^A Based on the material passing the 3-in. (75-mm) sieve. ^B If field sample contained cobbles or boulders, or both, add "with cobbles or boulders, or both" to group name. ^C Gravels with 5 to 12 % fines require dual symbols: GW-GM well-graded gravel with silt GW-GC well-graded gravel with clay GP-GM poorly graded gravel with silt GP-GC poorly graded gravel with clay ^D $Cu = D_{60}/D_{10}$ $Cc = (D_{30})^2 / (D_{10} \times D_{60})$ ^E If soil contains ≥ 15 % sand, add "with sand" to group name. ^F If fines classify as CL-ML, use dual symbol GC-GM, or SC-SM. ^G If fines are organic, add "with organic fines" to group name. ^H Sands with 5 to 12 % fines require dual symbols: SW-SM well-graded sand with silt SW-SC well-graded sand with clay SP-SM poorly graded sand with silt SP-SC poorly graded sand with clay ^I If soil contains ≥ 15 % gravel, add "with gravel" to group name. ^J If Atterberg limits plot in hatched area, soil is a CL-ML, silty clay. ^K If soil contains 15 to < 30 % plus No. 200, add "with sand" or "with gravel," whichever is predominant. ^L If soil contains ≥ 30 % plus No. 200, predominantly sand, add "sandy" to group name. ^M If soil contains ≥ 30 % plus No. 200, predominantly gravel, add "gravelly" to group name. ^N $PI \geq 4$ and plots on or above "A" line. ^O $PI < 4$ or plots below "A" line. ^P PI plots on or above "A" line. ^Q PI plots below "A" line.					

Order of Classification: 1) Consistency or Apparent Density, 2) Type of Soil, 3) Minor Soil Type(s), 4) Inclusions, 5) Layered Soils, 6) Color, 7) Water Content, 8) USCS Symbol, 9) Geological Name

Description of Frequently Used Laboratory Testing Procedures

Visual Engineering Classification

Visual classification was performed on all samples (though other means of refining the classification may also be used). The General Notes provided immediately following the Logs of Test Borings include a brief discussion of the general method used to visually classify the soil, which is based on the visual-manual procedure (ASTM D2488). The visual classification is used to assign an appropriate Unified Soil Classification System (USCS) group symbol. The USCS symbol is shown in parentheses following the textural description of the various strata on the boring logs.

Where more laboratory testing is performed (requiring both grain size and Atterberg limit tests), the classification may also be refined further based on USCS ASTM D2487.

Moisture Content (ASTM D2216)

Moisture content determination tests were performed in accordance with ASTM D2216. Samples were sealed in the field to retain the natural moisture content of the soil specimen. Samples were then dried at a constant temperature (approximately 110° C) overnight in an oven. After drying, the samples were weighed to determine the dry weight of the sample (and the loss in weight representing the water contained in the original sample). The moisture content of the specimen is expressed as a percent and is the weight of the water compared to the dry weight of the specimen.

Hand Penetrometer

A hand/pocket penetrometer was used to estimate the unconfined compressive strength of cohesive (clay) samples. In the hand penetrometer test, the shear strength of a cohesive soil sample is estimated by measuring the resistance of the sample to the penetration of a small, calibrated spring-loaded cylinder. The maximum capacity of the penetrometer is 4.5 tons per square foot. The shear strength is doubled and reported on the soil boring logs as an estimate of the unconfined compressive strength.

Grain Size Analyses (ASTM D6913, D7928, and/or D422-2017)

Grain size analyses were performed in accordance with ASTM D6913, D7928, and/or D422-2017 on selected soil samples to evaluate the gradation of the soil represented by the sample. The distribution of particle sizes larger than 75 micrometers (retained on the No. 200 sieve) is determined by sieving, while the distribution of particle sizes smaller than 75 micrometers is determined by a sedimentation process using a hydrometer.

Atterberg Limits Tests (ASTM D4318)

Determination of the Liquid Limit, Plastic Limit, and Plasticity Index of cohesive soils (known as Atterberg Limits) were performed in accordance with ASTM D4318. Fine-grained soils are tested to determine the Liquid Limit (LL) and Plastic Limits (PL), which are moisture contents that define boundaries between material consistency states. The LL and PL values define the transitional boundaries between non-plastic, plastic, and viscous fluid states. The plasticity index (PI) defines the complete range in water content for the plastic state.

Description of Frequently Used Laboratory Testing Procedures (continued)

Organic Content (Loss-On-Ignition) Tests (ASTM D7348)

The organic content of a soil is determined through a Loss-On-Ignition test performed in accordance with ASTM D2974 on soil samples suspected to contain significant organics. After the sample has been oven-dried, the soil sample is super-heated in a 440°C muffle furnace as a means to burn off all present organic matter. The weight of the remaining ash is used to calculate the percentage of organic matter as compared to the dry weight of the sample.

APPENDIX F

GEO-PROFESSIONAL BUSINESS ASSOCIATION (GBA) MESSAGE

Important Information about This Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, you can benefit from a lowered exposure to problems associated with subsurface conditions at project sites and development of them that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed herein, contact your GBA-member geotechnical engineer. Active engagement in GBA exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Understand the Geotechnical-Engineering Services Provided for this Report

Geotechnical-engineering services typically include the planning, collection, interpretation, and analysis of exploratory data from widely spaced borings and/or test pits. Field data are combined with results from laboratory tests of soil and rock samples obtained from field exploration (if applicable), observations made during site reconnaissance, and historical information to form one or more models of the expected subsurface conditions beneath the site. Local geology and alterations of the site surface and subsurface by previous and proposed construction are also important considerations. Geotechnical engineers apply their engineering training, experience, and judgment to adapt the requirements of the prospective project to the subsurface model(s). Estimates are made of the subsurface conditions that will likely be exposed during construction as well as the expected performance of foundations and other structures being planned and/or affected by construction activities.

The culmination of these geotechnical-engineering services is typically a geotechnical-engineering report providing the data obtained, a discussion of the subsurface model(s), the engineering and geologic engineering assessments and analyses made, and the recommendations developed to satisfy the given requirements of the project. These reports may be titled investigations, explorations, studies, assessments, or evaluations. Regardless of the title used, the geotechnical-engineering report is an engineering interpretation of the subsurface conditions within the context of the project and does not represent a close examination, systematic inquiry, or thorough investigation of all site and subsurface conditions.

Geotechnical-Engineering Services are Performed for Specific Purposes, Persons, and Projects, and At Specific Times

Geotechnical engineers structure their services to meet the specific needs, goals, and risk management preferences of their clients. A geotechnical-engineering study conducted for a given civil engineer

will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client.

Likewise, geotechnical-engineering services are performed for a specific project and purpose. For example, it is unlikely that a geotechnical-engineering study for a refrigerated warehouse will be the same as one prepared for a parking garage; and a few borings drilled during a preliminary study to evaluate site feasibility will not be adequate to develop geotechnical design recommendations for the project.

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project or purpose;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, the reliability of a geotechnical-engineering report can be affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If you are the least bit uncertain about the continued reliability of this report, contact your geotechnical engineer before applying the recommendations in it. A minor amount of additional testing or analysis after the passage of time – if any is required at all – could prevent major problems.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read the report in its entirety. Do not rely on an executive summary. Do not read selective elements only. *Read and refer to the report in full.*

You Need to Inform Your Geotechnical Engineer About Change

Your geotechnical engineer considered unique, project-specific factors when developing the scope of study behind this report and developing the confirmation-dependent recommendations the report conveys. Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the elevation, configuration, location, orientation, function or weight of the proposed structure and the desired performance criteria;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project or site changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept*

responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.

Most of the “Findings” Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site’s subsurface using various sampling and testing procedures. *Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing is performed.* The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgement to form opinions about subsurface conditions throughout the site. Actual site-wide subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team through project completion to obtain informed guidance quickly, whenever needed.

This Report’s Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, they are not final, because the geotechnical engineer who developed them relied heavily on judgement and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* exposed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals’ misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a continuing member of the design team, to:

- confer with other design-team members;
- help develop specifications;
- review pertinent elements of other design professionals’ plans and specifications; and
- be available whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction-phase observations.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note*

conspicuously that you’ve included the material for information purposes only. To avoid misunderstanding, you may also want to note that “informational purposes” means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. This happens in part because soil and rock on project sites are typically heterogeneous and not manufactured materials with well-defined engineering properties like steel and concrete. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled “limitations,” many of these provisions indicate where geotechnical engineers’ responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely.* Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a “phase-one” or “phase-two” environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually provide environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures.* If you have not obtained your own environmental information about the project site, ask your geotechnical consultant for a recommendation on how to find environmental risk-management guidance.

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, the engineer’s services were not designed, conducted, or intended to prevent migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, *proper implementation of the geotechnical engineer’s recommendations will not of itself be sufficient to prevent moisture infiltration.* Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. *Geotechnical engineers are not building-envelope or mold specialists.*

AS-BUILT

OCTOBER 2021

GENERAL

THIS PROJECT SHALL BE CONSTRUCTED IN ACCORDANCE WITH THE CONTRACT DOCUMENTS.

THE CONTRACTOR SHALL BE REQUIRED TO NOTIFY THE LOCAL
FIRE AND POLICE DEPARTMENTS 24 HOURS IN ADVANCE OF
PROPOSED WORK.

THE CONTRACTOR AND/OR HIS SUBCONTRACTOR SHALL
NOTIFY "MISS DIG", (1-800-482-7171 OR 811).

CONTRACTOR TO PROTECT EXISTING ABOVE GROUND AND BELOW GROUND FACILITIES INCLUDING: UTILITIES, POLES, TREES, SHRUBS AND OTHER VEGETATION UNLESS NOTED FOR REMOVAL ON THE PLANS, AND SHALL REPAIR OR REPLACE DAMAGED FACILITIES AT NO COST TO THE OWNER. TREES SHALL BE NEATLY TRIMMED. IT IS THE RESPONSIBILITY OF THE CONTRACTOR TO PROTECT AND MAINTAIN EXISTING SERVICES TO EXISTING HOMES AND BUSINESSES, INCLUDING SANITARY, WATER, GAS, CABLE AND OTHER UTILITIES.

CONTRACTOR SHALL PROTECT ALL COMMERCIAL AND INDUSTRIAL SITE FEATURES SUCH AS PLANTERS, MAIL BOXES, FENCES, LANDSCAPING, WALLS, WALKS, PORCHES, ETC, AND RESTORE TO ORIGINAL CONDITION IF DAMAGED EXCEPT AS NOTED. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.

ALL CONSTRUCTION STAGING AREAS SHALL BE APPROVED BY THE GREAT LAKE WATER AUTHORITY (GLWA) PRIOR TO START OF CONSTRUCTION. ANY AREAS BEYOND CONSTRUCTION LIMITS SECURED BY THE CONTRACTOR FOR USE AS CONSTRUCTION STAGING SHALL BE AT HIS OWN EXPENSE. THE RESTORATION OF ALL STAGING AREAS SHALL BE COMPLETED PRIOR TO FINAL ACCEPTANCE OF THE WORK OF THIS PROJECT. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.

THE CONTRACTOR SHALL REMOVE ALL SPRINKLER HEADS, LINES, ETC. THAT ARE WITHIN THE PROPOSED WORK AREA. THIS PIPE AND VALVE WORK SHALL BE CONSIDERED INCIDENTAL TO THE PROJECT.

UNDER CONSTRUCTION

WHEN EXCAVATING FOR CONSTRUCTION, THE CONTRACTOR SHALL TAKE ALL NECESSARY PRECAUTIONS TO PROTECT THE EXISTING UTILITIES AND STRUCTURES.

ALL SEWER TRENCHES SHALL BE BACKFILLED OR OTHERWISE PROTECTED OVERNIGHT.

STORM SEWER

SUMP DEPTH IS FROM LOWEST PROPOSED INVERT. CATC
BASIN (CB) MEANS 2 FT SUMP INCLUDED IN DRAINAGE
STRUCTURE PAY ITEM. INLETS (INL) DO NOT HAVE SUMPS.

MAINTAINING TRAFFIC

CONTRACTOR SHALL MAINTAIN SAFE, DUST FREE CONDITIONS ON EXISTING STREETS WHICH SHALL REQUIRE DAILY REMOVAL OF EARTH TRACKED OR SPILLED ON ROAD SURFACE, AND OTHER DUST CONTROL MEASURES AS REQUIRED BY THE PROJECT ENGINEER. EXCESSIVE DUST WILL NOT BE TOLERATED AT ANY TIME DURING CONSTRUCTION. PAYMENT FOR DUST CONTROL SHALL BE INCLUDED IN THE COST OF THE PROJECT.

EARTHWORK AND GRADING

ON-SITE FILL MATERIAL CAN BE USED IF THE SPECIFIED COMPACTION REQUIREMENTS CAN BE ACHIEVED. IF ON-SITE MATERIAL IS USED, IT SHALL BE CLEAN AND FREE OF FROZEN SOIL, ORGANICS, SOFT, OR OTHER DELETERIOUS MATERIALS.

A 6" TOPSOIL LAYER MUST BE MAINTAINED WHERE ALL PROPOSED RE-GRADING WORK IS LOCATED.

SEE SHEET C-2 AND C-6 FOR SOIL EROSION AND
SEDIMENTATION CONTROL INFORMATION.

UTILITIES

THE EXISTING UTILITIES LISTED BELOW AND SHOWN ON THESE PLANS REPRESENT THE BEST INFORMATION AVAILABLE AS OBTAINED FROM SURVEYS AND FROM UTILITY RECORD MAPS. THIS INFORMATION DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY TO NOTIFY THE PROPER UTILITIES BEFORE COMMENCING WORK. THE CONTRACTOR IS RESPONSIBLE TO VERIFY ALL EXISTING UTILITIES AND THEIR LOCATIONS AS PART OF THE CONSTRUCTION OF THIS PROJECT. ANY OMISSION OR VARIATION FROM THE LOCATIONS SHOWN PURSUANT TO ACTS OF THE CPA OF 1974 OR ANY CONDITION OF THIS CONTRACT NOTICE SHALL BE GIVEN TO MISS DIG PRIOR TO UNDERGROUND WORK TO BE PERFORMED. THE CONTRACTOR IS RESPONSIBLE TO LOCATE ALL EXISTING UTILITIES AND FIELD VERIFY BOTH LOCATIONS AND DEPTHS PRIOR TO ANY PROPOSED WORK BEING PERFORMED.

THE FOLLOWING UTILITY COMPANIES HAVE FACILITIES WITHIN THE PROJECT LIMITS:

DTE GAS
DTE ELECTRIC
DETROIT WATER AND SEWER DEPARTMENT

THE CONTRACTOR SHALL, BEFORE EACH DAYS WORK, OR WHEN MOVING TO A NEW AREA OF WORK, DETERMINE AND EVALUATE THE LOCATION OF ALL UNDERGROUND FACILITIES IN THE AREA. IF LOCATION STAKES HAVE BEEN MOVED OR DO NOT APPEAR CORRECT, THE CONTRACTOR SHALL NOT EXCAVATE UNTIL ALL UTILITIES HAVE HAD AN OPPORTUNITY TO CHECK OR RESTAKE THEIR LOCATIONS. ANY DELAYS INCURRED DUE TO CHECKING OR RESTAKING OF UTILITIES SHALL NOT BE A BASIS FOR ADDITIONAL COMPENSATION.

ALL UTILITIES SHALL BE PROTECTED DURING THE DURATION OF THE PROJECT.

PRIOR TO WORK ON FACILITIES BELONGING TO THE ABOVE AGENCIES, A MINIMUM OF 72 HOURS NOTICE MUST BE GIVEN IN ORDER TO INSURE PROPER INSPECTION BY THE RESPECTIVE AGENCIES.

THE CONTRACTOR SHALL LOCATE ALL ACTIVE UNDERGROUND UTILITIES PRIOR TO STARTING WORK, AND SHALL CONDUCT HIS OPERATIONS IN SUCH A MANNER AS TO INSURE THAT THOSE UTILITIES NOT REQUIRING RELOCATION WILL NOT BE DISTURBED.

FOR PROTECTION OF UNDERGROUND UTILITIES, THE CONTRACTOR SHALL DIAL (800) 482-7171, OR 811 A MINIMUM OF 3 FULL WORKING DAYS, EXCLUDING SATURDAY, SUNDAY, AND HOLIDAYS, PRIOR TO EXCAVATING IN THE VICINITY OF UTILITY LINES. ALL "MISS DIG" PARTICIPATING MEMBERS WILL BE ROUTINELY NOTIFIED. THIS DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY OF NOTIFYING UTILITY OWNERS WHO MAY NOT BE A PART OF THE "MISS DIG" ALERT SYSTEM.

RESTORATION

RESTORE AND STABILIZE ALL SLOPES IN ACCORDANCE WITH THE PLANS AND AS DESCRIBED IN THE CONTRACT DOCUMENTS.

ALL FINAL GRADES SHALL SLOPE TO DRAIN TOWARD CATCH BASINS, DITCHES, SWALES, CURBS, AND DRAINAGEWAYS UNLESS OTHERWISE NOTED.

THE CONTRACTOR SHALL NOT PERFORM ANY SIDE WORK
CONTRACTED PRIVATELY WITHIN THE CONSTRUCTION AREA.

SOIL EROSION AND SEDIMENTATION CONTROL GENERAL NOTES AND REQUIREMENTS:

1. CONTRACTOR SHALL NOTIFY THE WAYNE COUNTY SOIL EROSION OFFICE 48 HOURS BEFORE WORK IS TO BEGIN AT 734-326-3936.
2. ALL SOIL EROSION AND SEDIMENTATION CONTROL WORK SHALL CONFORM TO THE STANDARDS AND SPECIFICATIONS OF WAYNE COUNTY. THE CONTRACTOR SHALL OBTAIN THE SOIL EROSION CONTROL PERMIT FROM WAYNE COUNTY, AND SHALL MAINTAIN COMPLIANCE WITH THE PERMIT THROUGHOUT CONSTRUCTION.
3. CONTRACTOR SHALL PROVIDE A DETAILED SCHEDULE SHOWING DATES AND DURATION FOR EACH PHASE OF EARTH DISTURBANCE TO THE WAYNE COUNTY SOIL EROSION OFFICE FOR APPROVAL.
4. EROSION AND ANY SEDIMENT FROM WORK ON THIS SITE SHALL BE CONTAINED ON THE SITE AND NOT ALLOWED TO COLLECT ON ANY OFF-SITE AREAS OR IN WATERWAYS. WATERWAYS INCLUDE BOTH NATURAL AND MAN-MADE OPEN DITCHES, STREAMS, STORM DRAINS, LAKES, AND PONDS
5. CONTRACTOR SHALL PROVIDE AND INSTALL SOIL EROSION AND SEDIMENTATION CONTROL (SESC) DEVICES, AS SHOWN, BEFORE PROCEEDING WITH ANY OTHER SITE WORK. CONTRACTOR SHALL MAINTAIN ALL SESC DEVICES FOR THE DURATION OF THE CONSTRUCTION. AT THE END OF CONSTRUCTION, CONTRACTOR SHALL RESTORE ALL DISTURBED AREAS. ONCE GRASS IS ESTABLISHED, CONTRACTOR SHALL REMOVE AND DISPOSE OF ALL TEMPORARY SESC DEVICES AND COLLECTED DEBRIS. TEMPORARY CONTROLS SHALL BE REMOVED ONLY AFTER GETTING APPROVAL BY THE WAYNE COUNTY SOIL EROSION INSPECTOR.
6. CONTRACTOR SHALL INSPECT AND MAINTAIN SESC DEVICES ON A WEEKLY BASIS AND WITHIN 24 HOURS AFTER A STORM EVENT. THE CONTRACTOR SHALL REMOVE ACCUMULATED DEBRIS AND MAKE NECESSARY REPAIRS AS-DIRECTED BY THE ENGINEER.
7. CONTRACTOR IS TO MAINTAIN DRAINAGE OF THE SITE FOR THE DURATION OF CONSTRUCTION. DRAINAGE MATERIALS AND COLLECTED DEBRIS ARE REMOVED AT THE END OF CONSTRUCTION AND THE AREA RESTORED. ALL EXCESS EXCAVATED MATERIALS SHALL BE REMOVED FROM THE SITE AND DISPOSED OF PROPERLY. OWNER SHALL BE INFORMED OF THE DISPOSAL AREA(S), PRIOR TO ANY MATERIALS LEAVING THE SITE.
8. ALL STORM SEWERS USED TO CONVEY DISCHARGES FROM EXCAVATION DE-WATERING SYSTEMS SHALL BE FLUSHED AND CLEANED.
9. CONTRACTOR SHALL SWEEP ROADWAYS AT LEAST ONCE PER WEEK AND SCRAPE THE ROAD AT THE END OF EACH WORKDAY THROUGHOUT THE PROJECT WHILE EARTHWORK ACTIVITIES ARE IN PROGRESS. ANY MUD/DIRT TRACKED ONTO EXISTING CITY/COUNTY/STATE ROADS FROM THIS SITE, DUE TO CONSTRUCTION, SHALL BE PROMPTLY REMOVED BY THE CONTRACTOR/BUILDER. THIS WORK SHALL BE INCLUDED IN THE UNIT BID COSTS FOR SESC.
10. CONTRACTOR SHALL MAINTAIN SAFE, DUST FREE CONDITION ON EXISTING STREETS WHICH SHALL REQUIRE DAILY REMOVAL OF EARTH TRACKED OR SPILLED ON ROAD SURFACE, AND OTHER DUST CONTROL MEASURES AS REQUIRED BY THE PROJECT ENGINEER. EXCESSIVE DUST WILL NOT BE TOLERATED AT ANY TIME DURING CONSTRUCTION. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.
11. WHEN THE SITE IS READY FOR FINAL GRADING, RE-GRADE THE SITE AND COMPLETE ALL PAVEMENT WORK, THEN PERMANENTLY STABILIZE THE SITE PER CONTRACT REQUIREMENTS BY SEEDING.
12. PERMANENT SOIL EROSION AND SEDIMENTATION CONTROL MEASURES FOR ALL SLOPES, CHANNELS, DITCHES, OR ANY DISTURBED LAND AREA SHALL BE COMPLETED WITHIN 5 CALENDAR DAYS AFTER FINAL GRADING OR THE FINAL EARTH CHANGE HAS BEEN COMPLETED. WHEN IT IS NOT POSSIBLE TO PERMANENTLY STABILIZE A DISTURBED AREA AFTER AN EARTH CHANGE HAS BEEN COMPLETED OR WHERE SIGNIFICANT EARTH CHANGE ACTIVITY CEASES, TEMPORARY SOIL EROSION AND SEDIMENTATION CONTROL MEASURES SHALL BE IMPLEMENTED WITHIN 30 CALENDAR DAYS. ALL TEMPORARY SOIL EROSION AND SEDIMENTATION CONTROL MEASURES SHALL BE MAINTAINED UNTIL PERMANENT SOIL EROSION AND SEDIMENTATION CONTROL MEASURES ARE IMPLEMENTED.
13. DITCHES, SWALES, AND OTHER AREAS THAT WILL CHANNEL CONCENTRATED RUNOFF MUST BE STABILIZED WITHIN 15 DAYS OF EARTH DISTURBANCE. TEMPORARY ROCK CHECK DAMS WILL BE REQUIRED TO SLOW WATER TO NON-EROSIVE VELOCITIES IN AREAS OF CONCENTRATED FLOW.
14. AREAS OF EARTH CHANGE THAT ARE NOT STABILIZED BEFORE FALL SEEDING DEADLINE (NOV. 1) MUST BE TEMPORARILY STABILIZED WITH A STRAW MULCH SECURELY CRIMPED TO THE GROUND OR ALTERNATE METHOD APPROVED BY THE ENGINEER.

REMOVAL LEGEND

- REMOVE SIDEWALK
- REMOVE BRICK PAVERS
- REMOVE FENCE
- REMOVE CONCRETE PAVEMENT
- REMOVE ASPHALT
- CSO BASIN LIMITS

PLAN NOTES:

1. REFER TO SME ALTA SURVEY PLAN SHEET 2-LEIB FOR EXISTING ONSITE STORM SEWER INFORMATION.
2. EXISTING SITE INFORMATION NOT FOUND ON THIS SHEET CAN BE FOUND IN ALTA SURVEY PLAN SHEETS 2-LEIB AND 3-LEIB.
3. THE CONTRACTOR SHALL CONFINE ALL CONSTRUCTION OPERATIONS TO THE STAGING AREAS SHOWN ON THIS SHEET.
4. THE EXISTING UNDERGROUND CSO BASIN LIMITS ARE SHOWN ON THIS SHEET. MAXIMUM LOAD LIMIT ON THE BASIN TOP SLAB IS 300 PSF. THIS INCLUDES COMBINATIONS OF LOADS AT ANY ONE POINT IN TIME- EQUIPMENT, SOIL, ETC. THE CONTRACTOR IS RESPONSIBLE FOR THE EVALUATION OF THE EFFECTS OF ALL LOADS DUE TO CONSTRUCTION-RELATED ACTIVITIES ON THE BASIN AND OTHER EXISTING STRUCTURES ON THE SITE. SEE STRUCTURAL CAPACITY EVALUATION SPECIAL PROVISION FOR REQUIREMENTS.
5. SITE MUST BE SECURE AT THE END OF EACH WORK DAY. CONTRACTOR SHALL ONLY REMOVE AS MUCH FENCE AS HE CAN REPLACE THAT DAY. TEMPORARY FENCE SHALL MATCH OR EXCEED EXISTING FENCE.
6. UNDAMAGED BRICK PAVERS ARE TO BE SALVAGED WHERE POSSIBLE. DAMAGED BRICK PAVERS ARE TO BE REPLACED.
7. CONTRACTOR SHALL NOT EXERT ANY LOAD ON CONCRETE AREA INCLUDING ANY EQUIPMENT, DEBRIS, DIRT, ETC.

ISSUED FOR BIDS

August 14th, 2019

GENERAL

THIS PROJECT SHALL BE CONSTRUCTED IN ACCORDANCE WITH THE CONTRACT DOCUMENTS.

THE CONTRACTOR SHALL BE REQUIRED TO NOTIFY THE LOCAL FIRE AND POLICE DEPARTMENTS 24 HOURS IN ADVANCE OF PROPOSED WORK.

THE CONTRACTOR AND/OR HIS SUBCONTRACTOR SHALL NOTIFY "MISS DIG", (1-800-482-7171 OR 811).

CONTRACTOR TO PROTECT EXISTING ABOVE GROUND AND BELOW GROUND FACILITIES INCLUDING: UTILITIES, POLES, TREES, SHRUBS AND OTHER VEGETATION UNLESS NOTED FOR REMOVAL ON THE PLANS; AND SHALL REPAIR OR REPLACE DAMAGED FACILITIES AT NO COST TO THE OWNER. TREES SHALL BE NEATLY TRIMMED. IT IS THE RESPONSIBILITY OF THE CONTRACTOR TO PROTECT AND MAINTAIN EXISTING SERVICES TO EXISTING HOMES AND BUSINESSES, INCLUDING SANITARY, WATER, GAS, CABLE AND OTHER UTILITIES.

CONTRACTOR SHALL PROTECT ALL COMMERCIAL AND INDUSTRIAL SITE FEATURES SUCH AS PLANTERS, MAIL BOXES, FENCES, LANDSCAPING, WALLS, WALKS, PORCHES, ETC. AND RESTORE TO ORIGINAL CONDITION IF DAMAGED EXCEPT AS NOTED. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.

ALL CONSTRUCTION STAGING AREAS SHALL BE APPROVED BY THE GREAT LAKE WATER AUTHORITY (GLWA) PRIOR TO START OF CONSTRUCTION. ANY AREAS BEYOND CONSTRUCTION LIMITS SECURED BY THE CONTRACTOR FOR USE AS CONSTRUCTION STAGING SHALL BE AT HIS OWN EXPENSE. THE RESTORATION OF ALL STAGING AREAS SHALL BE COMPLETED PRIOR TO FINAL ACCEPTANCE OF THE WORK OF THIS PROJECT. NO ADDITIONAL PAYMENT WILL BE ALLOWED FOR THIS WORK.

THE CONTRACTOR SHALL REMOVE ALL SPRINKLER HEADS, LINES, ETC. THAT ARE WITHIN THE PROPOSED WORK AREA. THIS PIPE AND VALVE WORK SHALL BE CONSIDERED INCIDENTAL TO THE PROJECT.

UNDER CONSTRUCTION

WHEN EXCAVATING FOR CONSTRUCTION, THE CONTRACTOR SHALL TAKE ALL NECESSARY PRECAUTIONS TO PROTECT THE EXISTING UTILITIES AND STRUCTURES.

ALL SEWER TRENCHES SHALL BE BACKFILLED OR OTHERWISE PROTECTED OVERNIGHT.

STORM SEWER

SUMP DEPTH IS FROM LOWEST PROPOSED INVERT. CATCH BASIN (CB) MEANS 2 FT SUMP INCLUDED IN DRAINAGE STRUCTURE PAY ITEM. INLETS (INL) DO NOT HAVE SUMPS.

MAINTAINING TRAFFIC

CONTRACTOR SHALL MAINTAIN SAFE, DUST FREE CONDITIONS ON EXISTING STREETS WHICH SHALL REQUIRE DAILY REMOVAL OF EARTH TRACKED OR SPILLED ON ROAD SURFACE, AND OTHER DUST CONTROL MEASURES AS REQUIRED BY THE PROJECT ENGINEER. EXCESSIVE DUST WILL NOT BE TOLERATED AT ANY TIME DURING CONSTRUCTION. PAYMENT FOR DUST CONTROL SHALL BE INCLUDED IN THE COST OF THE PROJECT.

EARTHWORK AND GRADING

ONSITE FILL MATERIAL CAN BE USED IF THE SPECIFIED COMPACTION REQUIREMENTS CAN BE ACHIEVED. IF ON SITE MATERIAL IS USED, IT SHALL BE CLEAN AND FREE OF FROZEN SOIL, ORGANICS, SOFT, OR OTHER DELETERIOUS MATERIALS.

A 6" TOPSOIL LAYER MUST BE MAINTAINED WHERE ALL PROPOSED RE-GRADING WORK IS LOCATED.

SEE SHEET C-2 AND C-6 FOR SOIL EROSION AND SEDIMENTATION CONTROL INFORMATION.

UTILITIES

THE EXISTING UTILITIES LISTED BELOW AND SHOWN ON THESE PLANS REPRESENT THE BEST INFORMATION AVAILABLE AS OBTAINED FROM SURVEYS AND FROM UTILITY RECORD MAPS. THIS INFORMATION DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY TO NOTIFY THE PROPER UTILITIES BEFORE COMMENCING WORK. THE CONTRACTOR IS RESPONSIBLE TO VERIFY ALL EXISTING UTILITIES AND THEIR LOCATIONS AS PART OF THE CONSTRUCTION OF THIS PROJECT. ANY OMISSION OR VARIATION FROM THE LOCATIONS SHOWN, PURSUANT TO ACT 53 OF THE PA OF 1974 AS A CONDITION OF THIS CONTRACT NOTICE SHALL BE GIVEN TO MISS DIG PRIOR TO UNDERGROUND WORK TO BE PERFORMED. THE CONTRACTOR IS RESPONSIBLE TO LOCATE ALL EXISTING UTILITIES AND FIELD VERIFY BOTH LOCATIONS AND DEPTHS PRIOR TO ANY PROPOSED WORK BEING PERFORMED.

THE FOLLOWING UTILITY COMPANIES HAVE FACILITIES WITHIN THE PROJECT LIMITS:

DTE GAS
DTE ELECTRIC
DETROIT WATER AND SEWER DEPARTMENT

THE CONTRACTOR SHALL, BEFORE EACH DAYS WORK, OR WHEN MOVING TO A NEW AREA OF WORK, DETERMINE AND EVALUATE THE LOCATION OF ALL UNDERGROUND FACILITIES IN THE AREA. IF LOCATION STAKES HAVE BEEN MOVED OR DO NOT APPEAR CORRECT, THE CONTRACTOR SHALL NOT EXCAVATE UNTIL ALL UTILITIES HAVE HAD AN OPPORTUNITY TO CHECK OR RESTAKE THEIR LOCATIONS. ANY DELAYS INCURRED DUE TO CHECKING OR RESTAKING OF UTILITIES SHALL NOT BE A BASIS FOR ADDITIONAL COMPENSATION.

ALL UTILITIES SHALL BE PROTECTED DURING THE DURATION OF THE PROJECT.

PRIOR TO WORK ON FACILITIES BELONGING TO THE ABOVE AGENCIES, A MINIMUM OF 72 HOURS NOTICE MUST BE GIVEN IN ORDER TO INSURE PROPER INSPECTION BY THE RESPECTIVE AGENCIES.

THE CONTRACTOR SHALL LOCATE ALL ACTIVE UNDERGROUND UTILITIES PRIOR TO STARTING WORK, AND SHALL CONDUCT HIS OPERATIONS IN SUCH A MANNER AS TO INSURE THAT THOSE UTILITIES NOT REQUIRING RELOCATION WILL NOT BE DISTURBED.

FOR PROTECTION OF UNDERGROUND UTILITIES, THE CONTRACTOR SHALL DIAL (800) 482-7171, OR 811 A MINIMUM OF 3 FULL WORKING DAYS, EXCLUDING SATURDAY, SUNDAY AND HOLIDAYS, PRIOR TO EXCAVATING IN THE VICINITY OF UTILITY LINES. ALL "MISS DIG" PARTICIPATING MEMBERS WILL THUS BE ROUTINELY NOTIFIED. THIS DOES NOT RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY OF NOTIFYING UTILITY OWNERS WHO MAY NOT BE A PART OF THE "MISS DIG" ALERT SYSTEM.

RESTORATION

RESTORE AND STABILIZE ALL SLOPES IN ACCORDANCE WITH THE PLANS AND AS DESCRIBED IN THE CONTRACT DOCUMENTS.

ALL FINAL GRADES SHALL SLOPE TO DRAIN TOWARD CATCH BASINS, DITCHES, SWALES, CURBS, AND DRAINAGEWAYS UNLESS OTHERWISE NOTED.

THE CONTRACTOR SHALL NOT PERFORM ANY SIDE WORK CONTRACTED PRIVATELY WITHIN THE CONSTRUCTION AREA.

ELEVATION = 139.46

NOTE:
VERTICAL DATUM REFERENCED TO THE HISTORICAL CITY OF DETROIT VERTICAL CONTROL DATUM FOR PRECISE BENCH MARKS - CITY ENGINEERING DEPARTMENT. THE CONVERSIONS FACTOR OF 479.25 FEET IS ADDED TO THE HISTORICAL CITY VERTICAL DATUM TO DEFINE THE NAVD88 VERTICAL DATUM.

SOIL TYPES ON SITE

BrmubB - Brems-Urban land complex, dense substratum, 0 to 4 percent slopes

(SOIL INFORMATION TAKEN FROM THE UNITED STATES DEPARTMENT OF AGRICULTURE SOIL SURVEY)

FLOODPLAIN NOTE

THE SUBJECT SITE IS WITHIN ZONE "X" PER THE FEMA FIRM MAP OF CITY OF DETROIT, WAYNE COUNTY MICHIGAN, PANEL NUMBER 0285E, MAP NO. 26163C0285E, EFFECTIVE DATE: FEBRUARY 2, 2012.

LEGAL DESCRIPTION

LAND SITUATED IN THE CITY OF DETROIT, COUNTY OF WAYNE, STATE OF MICHIGAN:

THE NORTH 9 FEET OF LOT 33 AND ALL OF LOTS 34 THROUGH 40, HUNTS SUBDIVISION, ACCORDING TO THE RECORDED PLAT THEREOF, AS RECORDED IN LIBER 14, PAGE 92 OF PLATS, WAYNE COUNTY RECORDS.

COMMONLY KNOWN AS: 2198 MT. ELLIOTT, DETROIT, MI 48207

PARCEL ID NUMBER: WARD 15, TAX ITEM NO. 0139348

SURVEYORS NOTES:

- THE BEARING BASIS FOR THE SITE IS NAD83 MICHIGAN STATE PLANE, SOUTH ZONE, INTERNATIONAL FEET.
- DATE OF SURVEY: JANUARY 22, AND 23 2019.
- SOME FEATURES SHOWN ON SURVEY MAY BE OUT OF SCALE FOR CLARITY.
- DIMENSIONS ON THIS SURVEY ARE EXPRESSED IN FEET AND DECIMAL PARTS THEREOF UNLESS OTHERWISE NOTED.
- ACTUAL PROPERTY ACREAGE EQUALS 0.77 ACRES.
- THE LOCATION OF THE EXISTING UTILITIES AS SHOWN WERE OBTAINED FROM MUNICIPAL AND UTILITY COMPANIES RECORDS. NO GUARANTEE CAN BE MADE REGARDING THE COMPLETENESS OR EXACTNESS OF THE UTILITIES LOCATION. IT IS THE CONTRACTORS RESPONSIBILITY TO VERIFY IN THE FIELD THE LOCATION OF ALL UTILITIES.
- STRUCTURES HAVE BEEN LOCATED WITHIN THE ALLEY THAT FALL OUTSIDE OF THE LOCATION SHOWN ON THE PLAN.

\\PROJECTS\9805\CIVIL\LC-01.DWG 02/26/99 JPF

GENERAL NOTES

1. ALL SEWER CONSTRUCTION SHALL BE PERFORMED WITH MATERIALS AND WORKMANSHIP OF THE HIGHEST QUALITY FOR THE PARTICULAR PURPOSE AND SHALL STRICTLY CONFORM TO THE CURRENT STANDARDS AND SPECIFICATIONS OF THE DETROIT WATER AND SEWERAGE DEPARTMENT.
2. PAVEMENT REMOVAL, EXCAVATION, BACKFILLING AND REPLACEMENT OF THE PAVEMENT FOR THE ENTIRE WORK SHALL BE DONE BY THE CONTRACTOR.
3. ELEVATIONS OF EXISTING SEWERS ARE NOT KNOWN. APPROXIMATE ELEVATIONS SHOWN ON THE PROFILES ARE BASED ON AVAILABLE RECORD DRAWINGS FROM THE DETROIT WATER AND SEWERAGE DEPARTMENT. ELEVATIONS OF THE PROPOSED SEWERS ARE SUBJECT TO CHANGE TO SUIT ACTUAL ELEVATIONS OF EXISTING SEWERS. CONTRACTOR SHALL VERIFY LOCATIONS AND ELEVATIONS OF EXISTING SEWERS. CONTRACTOR SHALL SUBMIT SHOP DRAWINGS SHOWING PROPOSED SEWERS CONNECTION LOCATIONS AND ELEVATIONS (IF ANY) FOR ENGINEERS REVIEW AND APPROVAL PRIOR TO START OF WORK.
4. THE LOCATIONS AND ELEVATIONS OF EXISTING UTILITIES ARE SHOWN IN ACCORDANCE WITH THE SURVEY REFERENCE DRAWINGS ATTACHED). THE CONTRACTOR SHALL EXPOSE THESE UTILITIES, WHERE REQUIRED, TO DETERMINE ACTUAL LOCATIONS.
5. A MINIMUM CLEARANCE OF 18 INCHES VERTICALLY AND THREE AND ONE HALF FEET HORIZONTALLY SHALL BE MAINTAINED BETWEEN THE OUTSIDE SURFACE OF SEWERS AND OTHER UTILITIES, UNLESS OTHERWISE APPROVED BY THE ENGINEER AND D.W.S.D. IF A CONFLICT EXISTS BETWEEN THE SEWERS AND ANY OTHER UTILITY, THAT UTILITY AND ENGINEER SHOULD BE CONSULTED IMMEDIATELY. THE MINIMUM HORIZONTAL DISTANCE BETWEEN WATERMAIN AND SEWER SHALL BE 10 FEET UNLESS OTHERWISE APPROVED BY THE ENGINEER.
6. ELEVATION DATUM IS CITY OF DETROIT DATUM. COORDINATE SYSTEM IS CITY OF DETROIT HORIZONTAL SYSTEM.
7. IN COMPLIANCE WITH PUBLIC ACT 53 OF THE STATE OF MICHIGAN (EFFECTIVE AUG. 1, 1974). THE CONTRACTOR SHALL NOTIFY IN ADVANCE OF CONSTRUCTION ALL PUBLIC AND PRIVATE OWNERS HAVING EXISTING FACILITIES IN OR NEAR THE IMMEDIATE WORKING AREA. FOR CONVENIENCE THE KNOWN UTILITY OWNERS ARE LISTED ON THIS SHEET. THIS LISTING DOES NOT, HOWEVER, RELIEVE THE CONTRACTOR OF THE RESPONSIBILITY OF VERIFYING LOCATIONS AND NOTIFYING ALL UTILITY OWNERS AND MISS DIG (PHONE 482-7171 IN AREA CODE 800). IN EMERGENCY CASES, CONTRACTOR SHALL NOTIFY UTILITIES AS FOLLOWS:

DETROIT EDISON COMPANY	235-8892
DETROIT PUBLIC LIGHTING DEPT.	224-0500
DETROIT WATER AND SEWERAGE DEPT.	267-7401
AMERITECH TELEPHONE COMPANY	221-2121
COMCAST CABLE COMPANY	934-1608
MICHCON	577-7236
8. BIDDER SHALL VERIFY TYPES AND LOCATIONS OF PAVEMENTS AND CURBS OF STREETS AND ALLEYS (ESPECIALLY AT INTERSECTIONS) WITH RESPECT TO THEIR INTERFERENCE WITH THE SEWER RELOCATION AND/OR INSTALLATION AND SHALL INCLUDE COST OF CROSSING AND RESTORATION IN HIS BID PRICE.
9. ALL SIDEWALKS, DRIVEWAYS, SERVICE WALKS, CURBS, UTILITY POLES, TRAFFIC SIGNAL POLES, LIGHT POLES, TREES, LAWNS, D.S.R. TRACKS, ETC. ARE BASED ON THE PROJECT SURVEY AND MAY NOT ALL BE SHOWN ON ALL THESE DRAWINGS. THE BIDDER SHALL VISIT THE PROJECT SITE AND MAKE HIS OWN DETERMINATION OF THE SITUATION AND INCLUDE ALL WORK AND RESTORATION INVOLVING THESE IMPROVEMENTS IN HIS BID PRICE.
10. SEWER CONSTRUCTION OR REPLACEMENT IN CLOSE PROXIMITY TO UTILITY POLES, CATCH BASINS, TREES, ETC., MAY REQUIRE TUNNELING AND/OR THE USE OF CARRIER PIPES AS DIRECTED BY THE ENGINEER. CONTRACTOR SHALL INVESTIGATE THE PROPOSED ROUTES OF THE SEWER AND SHALL SATISFY HIMSELF THAT HIS BID IS INCLUSIVE OF ALL COSTS FOR THE EXECUTION OF THE CONTRACT WORK INCLUDING SUCH TUNNELING AND/OR THE USE OF CARRIER PIPES.
11. DAMAGE TO EXISTING MANHOLES AND SEWERS OCCURRING DURING PIPE INSTALLATION SHALL BE REPAIRED BY THE CONTRACTOR, AS DIRECTED BY THE ENGINEER, AT NO ADDITIONAL COST TO THE OWNER.
12. THE CONTRACTOR SHALL COMPLY AS APPLICABLE WITH THE REQUIREMENTS SET FORTH BY THE CITY OF DETROIT DEPARTMENT OF PUBLIC WORKS (D.P.W.) TRAFFIC ENGINEERING DIVISION, THE WAYNE COUNTY DEPARTMENT OF PUBLIC SERVICES (WCDPS) AND THE MICHIGAN DEPARTMENT OF TRANSPORTATION (M.D.O.T.).
13. IF A CRANE, BACKHOE OR A BOOM WILL BE USED IN THE VICINITY OF DETROIT EDISON OVERHEAD LINES, THE DETROIT EDISON COMPANY MUST BE NOTIFIED THREE WORKING DAYS PRIOR TO SUCH USE.
14. THE CONTRACTOR SHALL BE RESPONSIBLE FOR AVOIDANCE AND CLEANUP OF MUD TRACKED ONTO ADJACENT CITY STREETS FROM VEHICLES LEAVING THE JOBSITE. CLEANUP SHALL BE COMPLETED DAILY AND TO THE FULL SATISFACTION OF THE CITY OF DETROIT AUTHORITIES AND CONSTRUCTION MANAGER.
15. THE CONTRACTOR SHALL BE RESPONSIBLE FOR AVOIDANCE AND CLEANUP OF STREET SPILLAGE OF EXCAVATED OR BACK FILL MATERIALS ENTERING OR LEAVING THE SITE. CLEANUP OF MAJOR SPILLS SHALL BE COMPLETED IMMEDIATELY. OTHER SPILLS SHALL BE CLEANED, CONTINUALLY. ALL CLEANUP SHALL BE COMPLETED TO THE FULL SATISFACTION OF THE CITY OF DETROIT AUTHORITIES.
16. THE CONTRACTOR SHALL USE ALL MEANS NECESSARY TO PROPERLY MOISTEN ALL SURFACES AS REQUIRED TO PREVENT SOILS FROM BECOMING AIRBORNE AND CREATING A NUISANCE TO NEIGHBORING FACILITIES, THE PUBLIC, AND ANY CONCURRENT WORK ACTIVITIES. THE FINAL DETERMINATION OF THE SUCCESS OF THESE DUST CONTROL MEASURES SHALL BE BY THE CITY OF DETROIT AUTHORITIES.
17. ANY SITE DEWATERING NECESSARY TO MAINTAIN A SAFE AND EFFICIENT WORKING ENVIRONMENT.
18. ALL CONSTRUCTION WORK SHALL BE EXECUTED AND INSPECTED IN ACCORDANCE WITH ALL LOCAL, STATE AND FEDERAL CODES, RULES, ORDINANCES AND REGULATIONS.
19. ALL EXCAVATED MATERIALS SHALL BE REMOVED FROM THE SITE AND PROPERLY AND LEGALLY DISPOSED OF AT AN APPROVED OFF SITE LOCATION. NO EXCAVATED MATERIALS SHALL BE UTILIZED FOR ANY ON-SITE FILL REQUIREMENTS.

SEWER CONSTRUCTION NOTES

1. ALL SEWER WORK PERFORMED BY THE CONTRACTOR SHALL REQUIRE INSPECTION BY THE DETROIT WATER AND SEWERAGE DEPARTMENT (D.W.S.D.).
2. THE CONTRACTOR SHALL MAINTAIN FLOWS IN ALL EXISTING SEWERS DURING CONSTRUCTION. METHODS OF REROUTING OF FLOWS, PUMPING, OR TEMPORARY BLOCKING SHALL BE SUBMITTED BY THE CONTRACTOR FOR REVIEW AND APPROVAL BY THE ENGINEER.
3. CONTRACTOR SHALL PROVIDE EARTH SUPPORTING STRUCTURES WHERE REQUIRED TO PERFORM HIS OPERATION. CONTRACTOR SHALL SUBMIT DRAWINGS FOR THE PROPOSED EARTH SUPPORTING SYSTEM SIGNED AND CERTIFIED BY A REGISTERED PROFESSIONAL ENGINEER FOR THE REVIEW AND APPROVAL OF THE ENGINEER.
4. UTILITY SERVICES TO REMAIN IN SERVICE SHALL BE ADEQUATELY SUPPORTED DURING CONSTRUCTION TO MAINTAIN UNINTERRUPTED SERVICES. INTERFERENCE WITH OTHER UTILITIES REQUIRING RELOCATION SHALL BE COORDINATED WITH PARTICULAR UTILITY. CONTRACTOR SHALL RELOCATE SUCH UTILITY TO THE SATISFACTION OF ENGINEER AND THE UTILITY COMPANY.
5. THE CONTRACTOR SHALL CUT AND PLUG OR OTHERWISE MODIFY EXISTING SEWERS TO REMAIN IN SERVICE WHERE REQUIRED. THIS WORK IS TO BE DONE TO THE SATISFACTION OF THE ENGINEER AND DWSD.
6. THE CONTRACTOR SHALL INSTALL ALL PIPE AND FITTINGS NECESSARY TO COMPLETE THE CONNECTIONS SHOWN.
7. SEE "STANDARD SPECIFICATIONS FOR PAVING RELATED CONSTRUCTION" DATED JUNE, 1984 AS AMENDED, AND "SPECIFICATIONS FOR UTILITIES CUTS, PAVEMENT REMOVAL AND REPLACEMENT", DATED MAY 1984 OR CURRENT REVISION, CITY OF DETROIT ENGINEERING DIVISION, DEPARTMENT OF PUBLIC WORKS.
8. ALL EXCAVATED TRENCHES, SHAFTS OR PITS SHALL BE BACKFILLED WITH STRUCTURAL FILL IN ACCORDANCE WITH DWSD STANDARDS AND SPECIFICATIONS AS SHOWN ON THE DRAWINGS.
9. PLACE SAND BACKFILL WITHIN THREE FEET OF ALL STRUCTURES UNLESS SPECIFIED OTHERWISE.
10. THE SEWER PIPE BEDDING AND PIPE ENVELOPE SHALL BE AS PER DWSD'S SPECIFICATIONS
11. ALL PRECAST PRODUCTS SHALL CONFORM TO THE REQUIREMENTS OF ASTM C-478 UNLESS OTHERWISE NOTED ON THE PLANS.

GEOTECHNICAL REPORT

REFER TO THE SOILS REPORT PREPARED BY NTH CONSULTANT FOR INFORMATION RELATED TO THE EXISTING SUBSURFACE SOIL CONDITIONS ON THIS SITE.

TOPOGRAPHICAL AND BOUNDARY SURVEY

PREPARED BY METCO SERVICES AND CAN BE AVAILABLE TO BIDDERS UPON REQUEST.

SOIL EROSION AND SEDIMENTATION CONTROL NOTES

1. THE CONTRACTOR'S ATTENTION IS DIRECTED TO THE SPECIFICATIONS, SECTION 01110 ARTICLE 3.01, "EROSION CONTROL", WHERE REFERENCE IS MADE TO THE CONTRACTOR'S RESPONSIBILITIES CONCERNING THIS MATTER.
2. THE CONTRACTOR SHALL ARRANGE HIS CONSTRUCTION OPERATIONS IN SUCH A MANNER THAT THE CONSTRUCTION AREA WILL NOT BE SUSCEPTIBLE TO SOIL EROSION AND THAT THE CONSTRUCTION OPERATIONS WILL NOT CREATE ANY SILTATION PROBLEMS.
3. THE CONTRACTOR SHALL EMPLOY NECESSARY MEANS AND METHODS TO PREVENT EXCAVATED AND LOOSE SOIL MATERIAL FROM BEING COLLECTED ON TIRES OF TRUCKS AND OTHER EQUIPMENT AND BEING DEPOSITED ON STREETS AND ROADS TO AND FROM THE CONSTRUCTION SITE.
4. THE CONTRACTOR SHALL CONTROL DUST AT THE CONSTRUCTION SITE AND ON ALL PUBLIC STREETS USED AS HAUL ROADS.
5. THE DISTANCE BETWEEN THE POINT OF COMPLETE BACKFILLING AND THE PIPE LAYING SHALL NOT EXCEED 40 FEET.
6. THE CONTRACTOR SHALL EMPLOY POSITIVE MEANS TO PREVENT SOIL AND OTHER DEBRIS FROM ENTERING THE EXISTING STREET DRAINAGE SYSTEM. IT IS THE CONTRACTOR'S RESPONSIBILITY TO MAINTAIN THE EXISTING CATCH BASIN AND DRAIN SYSTEM TO AT LEAST THE CONDITIONS PRIOR TO CONSTRUCTION. IN ADDITION TO THE ABOVE REQUIREMENTS, THE CONTRACTOR'S ATTENTION IS DIRECTED SPECIFICALLY TO DIVISION 146, "EROSION CONTROL PROGRAM" OF THE CITY OF DETROIT DEPARTMENT OF PUBLIC WORKS (D.P.W.) CITY ENGINEERING DIVISION'S CURRENT "STANDARD SPECS FOR PAVING AND RELATED CONSTRUCTION."
7. THE CONTRACTOR SHALL PERFORM ALL ACTIVITIES NECESSARY TO COMPLY WITH THE SOIL EROSION AND SEDIMENTATION CONTROL PROGRAM AT NO ADDITIONAL COST TO THE OWNER.

SITE PLAN NOTES

1. THE CONTRACTOR SHALL COORDINATE GAS SERVICE CONNECTION WITH MICHCON GAS CO.
2. NEW 6" WATER SERVICE SHALL BE INSTALLED PER CURRENT "DWS" AND PLUMBING STANDARDS.
3. ON SITE STORM SEWERS, CATCH BASINS, AND MANHOLES SHALL BE IN ACCORDANCE WITH THE CURRENT "DWS" AND PLUMBING STANDARDS.
4. THE CONTRACTOR SHALL SECURE ALL NECESSARY PERMITS FROM LOCAL AND STATE AUTHORITIES FOR WATER SERVICE, STORM SERVICE, GAS SERVICE, CURB CUTS AND DRIVEWAYS.
5. THE CONTRACTOR SHALL PROVIDE ALL SIGNS AND PAVEMENT MARKINGS AS SHOWN ON THE SITE PLAN AND IN THE SPECIFICATIONS.
6. THE CONTRACTOR SHALL CALL "MISS DIG" AT LEAST 72 HOURS BEFORE STARTING ANY EXCAVATION WORK.
7. ALL WORK WITHIN MT. ELLIOTT AVE RIGHT OF WAY (R.O.W.) SHALL BE IN ACCORDANCE WITH THE CITY OF DETROIT DEPARTMENT OF PUBLIC WORKS (DPW) STANDARDS.
8. THE CONTRACTOR SHALL PROVIDE A SIGN FOR PHYSICALLY HANDICAPPED PARKING SPACE.
9. THE CONTRACTOR SHALL COORDINATE HIS WORK WITH ALL UTILITIES FOR WORK WITHIN THE R.O.W.
10. LOCATIONS OF UNDERGROUND UTILITIES SHOWN ARE APPROXIMATE AND BASED ON BEST AVAILABLE DRAWINGS. THE CONTRACTOR SHALL FIELD VERIFY SIZE, DEPTH AND LOCATION OF UTILITIES PRIOR TO START OF WORK.
11. ALL SOIL EROSION AND SEDIMENTATION SHALL BE IN ACCORDANCE WITH DETAILS SHOWN ON SHEET D-98-10-010.
12. THE CONTRACTOR SHALL INSTALL 6" HIGH CHAIN LINK FENCE AROUND PERIMETER OF THE SITE INCLUDING A 3' WIDE MAN GATE AT ALLEY AND 30' CANTILEVER AUTOMATIC VEHICLE ENTRY CHAIN LINK GATE AT MT. ELLIOTT DRIVEWAY. THE CONTRACTOR SHALL COORDINATE WITH GATE MANUFACTURER FOR LOCATION OF ACCESS KEYS PEDESTALS AND GUIDES. THE PROPOSED GATE INSTALLATION SHALL BE AS PER DWS SECURITY SECTION GUIDELINES.

- MANHOLE STEP NOTES:
- MANHOLE STEPS SHALL BE INSTALLED IN WELL WALL WHERE HEIGHT FROM TOP OF PIPE TO TOP OF WELL EXCEEDS 5'-0".
 - MANHOLE STEPS SHALL CONFORM TO THE REQUIREMENTS FOR "ALUMINUM ALLOY EXTRUDED BARS, RODS, SHAPES AND TUBES", A.S.T.M. B-221 (CURRENT), ALLOY 6061, TEMPER T-6 OR APPROVED EQUAL.
 - EITHER THE FLARED LEG OR PARALLEL LEG STEP MAY BE USED FOR POURED IN PLACE CONCRETE CONSTRUCTION OR IN WETCAST MANHOLE UNITS.
 - THE PARALLEL LEG STEP SHALL BE USED IN EXISTING STRUCTURES BY PLACING IN DRILLED HOLES AND GROUTING WITH NON-SHRINK GROUT.
 - FLARED LEGS SHALL BE RADIAL TO THE MANHOLE WALL.

- IN LIEU OF GROOVES, ALTERNATE FOOTHOLD CONFIGURATION WILL BE CONSIDERED FOR APPROVAL.
- THE VERTICAL SPACING BETWEEN INSTALLED STEPS SHALL NOT BE MORE THAN SIXTEEN INCHES.
- ALL MANHOLE STEPS SHALL COMPLY WITH SAFETY STANDARDS (PART 3 FIXED LADDERS) AS ESTABLISHED BY THE OCCUPATIONAL SAFETY STANDARDS COMMISSION OF THE MICHIGAN DEPARTMENT OF LABOR.

- GENERAL NOTES:**
- APPROXIMATE LOCATION OF KNOWN EXISTING UTILITIES ARE MARKED ON THE DRAWING FOR INFORMATION ONLY. IT IS THE RESPONSIBILITY OF THE CONTRACTOR TO VERIFY UTILITY LOCATIONS AND NOTIFY ALL UTILITY OWNERS AND MISS DIG (PHONE 1-800-482-7171) 72 HOURS BEFORE DIGGING AS REQUIRED BY PUBLIC ACT 53 OF STATE OF MICHIGAN EFFECTIVE AUGUST 1, 1974. HAND DIG OVER GAS MAIN, SHALLOW ELECTRICAL AND TELEPHONE CABLES. SUPPORT GAS MAIN, ELECTRICAL AND TELEPHONE CABLES OVER SEWER TRENCH.
 - CONTRACTOR SHALL RESTORE ALL AREAS AFFECTED BY THE SEWER CONSTRUCTION PROCESS. RESTORATION INCLUDE REMOVAL OF CONSTRUCTION MATERIAL, PLACEMENT OF TOPSOIL, SEEDING, MULCHING, AND REPLACEMENT OF ALL TREES REMOVED HAVING A STUMP DIAMETER OF 6" OR MORE. NEW TREES SHALL BE PLACED IN ACCORDANCE WITH THE CITY OF DETROIT'S REQUIREMENTS.
 - THE CONTRACTOR SHALL REMOVE PAVEMENT AS NEEDED TO PERFORM HIS WORK. THE CONTRACTOR SHALL INSTALL NEW PAVEMENT IN ACCORDANCE WITH CITY OF DETROIT STANDARDS. THE MINIMUM PAVEMENT REPLACEMENT THICKNESS SHALL BE 9" OF REINFORCED CONCRETE PAVEMENT. THE EXISTING PAVEMENT ON KERCHEVAL, BELLEVUE, AND JEFFERSON ROADS IS 8" TO 9" NON-REINFORCEMENT CONCRETE WITH 6" MINIMUM BITUMINOUS SURFACING. THESE ROADS HAVE BEEN RESURFACED A FEW TIMES. ALL THE ABOVE INFORMATION HAS BEEN BASED ON AVAILABLE INFORMATION FROM THE CITY OF DETROIT. THE CONTRACTOR SHALL FIELD VERIFY THE THICKNESS AND TYPE OF EXISTING PAVING.
 - UNLESS NOTED OTHERWISE EXISTING STRUCTURES, UTILITIES, INCLUDING CONCRETE DRIVES, CURBS, WALKS, FENCES, POLES, PIPES, CATCH BASINS, ETC., REMOVED DURING CONSTRUCTION OF NEW SEWER SHALL BE REPLACED BY THE CONTRACTOR.
 - THE CONTRACTOR SHALL BE RESPONSIBLE TO PROVIDE ADEQUATE EARTH SUPPORT SYSTEM AS REQUIRED. FOR ALL THE EXCAVATION DURING CONSTRUCTION ENSURING THE INTEGRITY OF ALL THE EXISTING STRUCTURES, PAVEMENTS AND UTILITIES. EXISTING FACILITIES DAMAGED AS A RESULT OF CONTRACTOR'S OPERATIONS SHALL BE REPAIRED TO ITS ORIGINAL CONDITION AT NO COST TO THE OWNER.
 - THE CONTRACTOR SHALL SUBMIT SHOP DRAWINGS, CERTIFIED BY PROFESSIONAL ENGINEER REGISTERED IN MICHIGAN, FOR THE EARTH SUPPORT SYSTEM FOR ENGINEER'S REVIEW. THESE DRAWINGS SHALL ALSO INCLUDE THE SEQUENCES OF CONSTRUCTION.
 - THE CONTRACTOR SHALL BE RESPONSIBLE TO PROVIDE ADEQUATE PROTECTION TO CONTROL SEDIMENTATION INTO THE EXISTING DRAINAGE SYSTEM DURING CONSTRUCTION.
 - THE CONTRACTOR SHALL BE RESPONSIBLE FOR PROVIDING TRAFFIC CONTROL MEASURES AROUND THE WORK AREAS. THESE MEASURES SHALL BE SUBMITTED TO THE ENGINEER FOR REVIEW AND APPROVAL PRIOR START OF WORK.
 - SOIL BORING PROFILES SHOWN ON SEWER PROFILES ARE FOR INFORMATION PURPOSES ONLY. CONTRACTOR SHALL SATISFY HIMSELF TO THE ACCURACY OF THE SOIL CONDITIONS PRIOR TO START OF CONSTRUCTION.
- BENCH MARKS**

22-OCT-2021

Revised 09-30-2015 by Data Integrity/Mapping Tech
File: Png_Des_Bdry_w_Emails_Sept_2015.mxd

Please note:

All documentation to be reviewed at the Utility Coordination Meeting must be received at least 10 business days prior to the meeting date: Send all information to the Regional Planning Office where your project is located. **See Planning and Design Service Area Map.**

For all future correspondence on this request, please contact the Regional Planning Office for your project.

To help facilitate timely electric utility coordination, please note the following:

Provide conflict list and associated drawings.

Specifically identify conflicts and provide locations of conflicts.

Poles and/or wire conflicts.

Street lighting posts and/or underground cable.

Underground facilities, i.e. cable, conduit, manholes and ground mounted equipment.

Send documents to the Regional Planning Office.

Documents must be received no less than 10 days before the Utility Coordination Meeting.

Requesting Company / Owner Agency to conduct Utility Coordination Meeting

The purpose of this meeting is to confirm design conflicts and discuss design options and/or relocation options.

Meeting should occur as soon as possible, but after the following have been completed.

Utilities have been plotted on Requesting Company / Owner Agency's design documents.

Conflicts have been identified by Requesting Company / Owner Agency.

Conflict list has been created by Requesting Company / Owner Agency.

Requesting Company / Owner Agency to conduct Pre-Construction Meeting

The purpose of this meeting is to confirm or coordinate the resolution of conflicts/relocations identified at the Utility Coordination Meeting.

Conflict information must be communicated prior to the Utility Coordination Meeting. Failure to do so will likely prevent DTE from meeting the project's utility relocation time line.

Things to Remember

Designers should be instructed to make every effort to avoid utility relocations.

Underground relocations can take up to 18 months or longer.

Overhead relocations can take 6 months or longer depending on the facilities involved.

TRUE COPY CERTIFICATE

Form C of D-16-CR

STATE OF MICHIGAN, }
City of Detroit } ss.

CITY CLERK'S OFFICE, DETROIT

I, Janice M. Winfrey, City Clerk of the City of Detroit, in said
State, do hereby certify that the annexed paper is a TRUE COPY OF Resolution
adopted (passed) by the City Council at session of

November 23, 2021

and approved by Mayor

November 29, 2021

as appears from the Journal of said City Council in the office of the City Clerk of Detroit, aforesaid;
that I have compared the same with the original, and the same is a correct transcript therefrom, and of the
whole of such original.

In Witness Whereof, I have hereunto set my hand
and affixed the corporate seal of said City, at

Detroit, this 6th

day of January A.D. 2021

November 4th, 2021

Honorable City Council:

RE: Petition No. 1584 – Great Lakes Water Authority request to vacate to utility easement the public alleys bounded by Waterloo Avenue, Meldrum Avenue, Kercheval Avenue, and Mt. Elliot Street.

Petition No. 1584 – Great Lakes Water Authority request to vacate to utility easement the public alleys bounded by Waterloo Avenue, 50 ft. wide, Meldrum Avenue, 60 ft. wide, Kercheval Avenue, 80 ft. wide, and Mt. Elliot Street, 66 ft. wide.

The petition was referred to the City Engineering Division – DPW for investigation (utility review) and report. This is our report.

The request is made as part of a consolidation of property by adjacent owners.

The request was approved by the Solid Waste Division – DPW, and Traffic Engineering Division – DPW, and City Engineering – DPW.

Detroit Water and Sewerage Department (DWSD) has no objection to the vacation and conversion to utility easement provided certain provisions are met. The DWSD provisions are a part of the attached resolution.

All other involved City Departments, and privately owned utility companies have reported no objections to the vacation and conversion to utility easement of the alley. Provisions protecting utility installations are part of the attached resolution.

I am recommending adoption of the attached resolution.

Respectfully submitted,

Richard Doherty, P.E., City Engineer
City Engineering Division – DPW

/JK

Cc: Ron Brundidge, Director, DPW
Mayor's Office – City Council Liaison

BY COUNCIL MEMBER

Benson

RESOLVED, the public alleys bounded by Waterloo Avenue, 50 ft. wide, Meldrum Avenue, 60 ft. wide, Kercheval Avenue, 80 ft. wide, and Mt. Elliot Street, 66 ft. wide; further described as land in the City of Detroit, Wayne County, Michigan being:

1. The north-south alley, 20 ft. wide, lying easterly of and adjacent to lots 1 through 4 and lying westerly of and adjacent to lot 5 of "DuPont's Subdivision" as recorded in Liber 3, Page 49 of Plats, Wayne County Records.
2. The east-west alley, 10 ft. wide, lying southerly of and adjacent to lot 5 through 11 of "DuPont's Subdivision" as recorded in Liber 3, Page 49 of Plats, Wayne County Records.
3. The north-south alley, 20 ft. wide, lying easterly of and adjacent to lots 31 through 40 and lying westerly of and adjacent to lots 21 through 30 of "Hunt's Subdivision" as recorded in Liber 14, Page 92 of Plats, Wayne County Records.
4. The north-south alley, 20 ft. wide, lying easterly of and adjacent to lots 1 through 6 and lying westerly of and adjacent to lots 17 through 22 of "Traugott Schmidt's Subdivision" as recorded in Liber 9, Page 86 of Plats, Wayne County Records.
5. The east-west alley, 20 ft. wide, lying southerly of and adjacent to lots 6 and 17 and lying northerly of and adjacent to lots 7 through 16 of "DuPont's Subdivision" as recorded in Liber 3, Page 49 of Plats, Wayne County Records.

Be and the same is hereby vacated as public right-of-way and converted into a private easement for public utilities of the full width of the right-of-way, which easement shall be subject to the following covenants and agreements, uses, reservations and regulations, which shall be observed by the owners of the lots abutting on said right-of-way and by their heirs, executors, administrators and assigns, forever to wit:

First, said owners hereby grant to and for the use of the public an easement or right-of-way over said vacated public alley herein above described for the purposes of maintaining, installing, repairing, removing, or replacing public utilities such as water mains, sewers, gas lines or mains, telephone, electric light conduits or poles or things usually placed or installed in a public right-of-way in the City of Detroit, with the right to ingress and egress at any time and over said easement for the purpose above set forth.

Second, said utility easement or right-of-way in and over said vacated alley herein above described shall be forever accessible to the maintenance and inspection forces of the utility companies, or those specifically authorized by them, for the purpose of inspecting, installing, maintaining, repairing, removing, or replacing any sewer, conduit, water main, gas line or main, telephone or light pole or any utility facility placed or installed in the utility easement or right-of-way. The utility companies shall have the right to cross or use the driveways and yards of the adjoining properties for ingress and egress at any time to and over said utility easement with any necessary equipment to perform the above mentioned task, with the understanding that the utility companies, other than that specifically prohibited by this resolution, shall restore the easement surface to a satisfactory condition,

*Subject: TM-24 Site-Civil Design
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

As a part of the scope of work, the Design Team has evaluated alternatives and design criteria which apply to the site improvements described as OKW-SITE-1, and LEIB-SITE-1 in the Engineering Services Agreement for the Combined Sewer Overflow (CSO) Facilities Improvements Project.

The Design Team's recommendation for site improvement LEIB-SITE-1 is to provide fencing and security for the new access drive and relocated parking spaces as shown in fencing and security Alternative 2, and to provide drainage as shown in drainage Alternative 4. The recommended alternatives will increase the construction cost which was initially estimated in the CS-299 report.

The Design Team's recommendation for site improvement OKW-SITE-1 is to provide the pavement cross section as identified in the CS-299 report, with shoulder on the outer edge of the road and bioswales to provide improved drainage around the facility. The recommended alternatives will increase the construction cost which was initially estimated in the CS-299 report.

1.0 Introduction and Purpose

The purpose of this technical memo is to support the design of the site improvements described as OKW-SITE-1, and LEIB-SITE-1 in the Engineering Services Agreement for the CSO Facilities Improvements Project. These improvements are also referenced in the CS-299 CSO Facility Needs Assessment Report dated April 9, 2021 (CS-299 Report). The improvements are intended to improve facility reliability, flexibility, operation, maintenance, and safety to support planned increases in utilization for the Oakwood and Leib CSO facilities upon completion of other projects

that are being planned for implementation. The Oakwood Facility is located at 12220 Pleasant Street, Detroit, MI 48217. The Leib Facility is located at 2198 Mt Elliot Street Detroit Michigan.

OKW-SITE-1 consists of paving an existing gravel drive that goes around the CSO basin, fixing drainage issues and damaged concrete around the CSO basin area, sealing the existing concrete driveway areas, and removing the overgrowth of vegetation in the surge basin area.

The above items are to be addressed by incorporating the following items into the design at this site:

- Add paved road around the basin – Engineer shall replace the gravel service road with new reinforced concrete pavement that will extend around the perimeter of the basin connecting with the existing concrete service road on either side of the basin. See CS-299 Report Figure OKW-SITE-1- ALT-2 in Volume 6 – Appendices, Appendix B (Attachment B), for the location of new pavement. The concrete pavement should have a minimum 16-foot. width. Engineer shall provide all design services including roadway design, pavement design, drainage, and other design required to implement this improvement.
- Address drainage around CSO basin – Engineer shall address the existing poor drainage around the CSO basin from the basin roof runoff and address any necessary drainage improvements as a result of paving the gravel roadway. Engineer shall ensure proper drainage and detailed grading are performed to direct drainage away from the buildings and away from site vaults or electrical manholes.
- Swale expansion - For drainage improvements, Engineer shall consider, amongst other things, the existing drainage swale be excavated to increase its volume to accept the flow that is discharged from the west side of the basin roof during wet weather. CS-299 Report Figure OKW-SITE-1-ALT-2 in Volume 6 – Appendices, Appendix B, (Attachment B) presents the proposed layout for these improvements. The flat area between the basin and existing service drive is recommended to be regraded away from the basin, and new catch basins and a storm sewer be added to capture the surface runoff and direct the flow under the service drive to discharge into the new bioswale.
- Replace site concrete (drive and sidewalk) – Engineer shall provide engineering services to replace damaged concrete sidewalk or driveway sections, and to establish proper sealing against the building, expansion joints and/or other type of joints to ensure longevity of improvements.
- Remove vegetation from surge basin area – Engineer shall perform necessary engineering services to clear out the surge basin area.
- Seal site concrete drive areas – Engineer shall provide engineering services to seal existing concrete driveway.

LEIB-SITE-1 consists of confirming the size, configuration, and geometry of a new access drive from Meldrum St. and associated changes to the Leib parking lot, parking lot striping, protection of the transformer with bollards, fencing, motorized vehicle gate, security badge access, and necessary electrical needed to facilitate the improvements. Three parcels in which the driveway is intended to cross are owned by Detroit Water and Sewerage Department (DWSD). The alley in between the existing Leib Facility parcel and these three parcels has been vacated. Electrical and telecommunications providers have utilities in the influence of the proposed driveway.

The above items are to be addressed by incorporating the following items into the design at this site:

- Perform all appropriate utility coordination with associated utilities to permit the improvements to be constructed. This includes, but may not be limited to, filling out permits, holding meetings, providing drawings, responding to utility requests for information, and any other coordination necessary to successfully coordinate with them for the proposed improvements.
- Engineer shall provide all design services to construct the alternate access to the site, as shown in Attachment B, Figure LEIB-SITE-1- ALT-2, in Volume 6 Appendices, Appendix B and also make improvements along Mount Elliot at the Leib influent and effluent structures where pavement has settled. Engineer shall confirm the size, configuration, and geometry of the new access and associated changes to the parking lot, parking lot striping, protection of the transformer with bollards, fencing, motorized vehicle gate, security badge access, and necessary electrical needed to facilitate the improvements. Engineer shall perform design services to construct all necessary improvements to facilitate the new driveway. Engineer's Work shall include, at a minimum, the following:
 - Engineer shall provide necessary property boundary surveys and land acquisition services as requested by Owner. Work performed under acquisition (if necessary) shall be billed in accordance with, hourly rates and a not-to-exceed (NTE) Allowance for this Work.
 - Engineer shall provide all services required to obtain right-of-way (ROW) permits and properly coordinate with DWSD and City of Detroit departments on improvements in the road rights of way and required maintenance of traffic during construction of the improvements along Meldrum St.
 - Engineer shall provide site design, road design, pavement design, electrical design, security design (for gate badge access), and maintenance of traffic services required to construct a new entrance at the rear of the site, as shown and described in Attachment B. This includes all services required to complete the design.

- Engineer shall evaluate impact/traffic protection requirements around the existing building transformer and incorporate into the design Drawings/Specifications.
- Engineer shall coordinate with Owner's Security team for additional cameras (see LEIB-I&C-1A), and site security fencing and associated security systems.

2.0 Existing Systems Description and Conditions

Existing conditions at both sites are described and presented in Technical Memorandum (TM) -11 Survey and Site Constraints. TM – 11 provides pictures taken from site visits at both sites. The appendix of TM -11 documents the draft base map surveys, utility investigations, and geotechnical reports which have been recently completed at both sites, as well as relevant record drawings and property information which are relevant to the proposed paving and drainage at each site.

Topographic surveys of the Oakwood and Leib sites, as well as adjoining ROWs and parcels were performed in Fall of 2022 utilizing aerial imagery and conventional ground surveying methods. Digital terrain models were computed, and contours developed at one-foot intervals. Facility records and third-party utility information obtained from MISS DIG requests were obtained and checked against the survey field information to develop site base maps of existing conditions to be used for conceptual design. Underground utilities are shown based upon a combination of record information along with actual field measurements for above-ground manifestations of underground utilities. Mapping in both pdf and CAD formats is provided and a set of base map drawings have been produced for each site using Civil 3D.

Two Draft Geotechnical Reports have been prepared, one for each site. At the Oakwood Site, the field exploration program consisted of six hand-auger probes which were extended to depths approximately 4 to 6 feet below existing grades to support the design of new pavement and a potential bioswale feature. At the Leib Site, the field exploration program consisted of two soil borings which extended to 10 feet below existing grades to support the design of new concrete pavement. Geotechnical recommendations for the proposed pavement section are provided in the geotechnical reports.

The Oakwood and Leib CSO facilities, both have established stormwater management systems in place. Both facilities are proposed to undergo paving projects that will require new stormwater management systems to handle the additional runoff generated.

Figures 2-1 and 2-2 show the existing storm sewer layout and storm catchment area delineations at the Oakwood facility.

Figure 2-1
Oakwood CSO Facility Site Plan – Existing Storm Sewer Conveyance Map

Figure 2-2
Oakwood CSO Facility Site Plan – Existing Stormwater System Catchment Area Delineation

Generally, the storm water collection system carries flows from the north end of the Oakwood facility to the south end. All on-site collected storm water is routed to the head of the facility where it is outletted into Junction Chamber 1. This storm water, as well as the combined wastewater from

the entirety of the Oakwood facility's service area, enters Junction Chamber 1 before it is pumped by either the sanitary or storm pumps at the facility.

The area around the CSO basins is the primary area of concern at the Oakwood facility, as this will be the site of the new paving. Presently, runoff from the roof of the CSO basin is evenly distributed to the east and west sides of the facility. Rain that falls on the CSO basin roof travels to the east or west edge and falls through scuppers that drop the flow on to concrete splash blocks on the ground at the base of the building. As overland flow, the runoff generally travels over the gravel road, to an earthen swale, and into the stormwater collection system. A swale exists on both the east and west sides of the building.

The overland flow from the basin roof across the gravel road has led to scouring of the road causing potholes and reduced accessibility around the CSO basin building. This issue has presented the need for the proposed paved road and updated stormwater management system.

Figures 2-3 and **2-4** show the existing storm sewer layout and storm catchment area delineations at the Leib facility.

Figure 2-3
Leib CSO Facility Site Plan – Existing Storm Sewer Conveyance Map

Figure 2-4
Leib CSO Facility Site Plan – Existing Stormwater System Catchment Area Delineation

There are two separate storm water management systems in place at the Leib facility. **Figure 2-3** shows one system in the Leib parking lot and one system in the grass pavers. All parking lot runoff and runoff from the north end of the facility roof flows into a storm sewer system that outlets via a drop manhole into the influent box at the head of the facility’s screening and disinfection operations. Runoff from the south side of the roof and on the grass pavers flows into a drainpipe system that outlets at the Toward Treatment Sewer junction chamber in the facility below. All other rainfall on the facility’s property is infiltrated into the ground or flows off of the site.

Runoff generated on the vacant lots adjacent to the Leib facility flows to either the alley between Leib and the vacant lots or to Meldrum Street. The direction of the runoff is determined by a highpoint that generally runs north-south. Flow to the alley is captured by catch basins that direct flow into a 10-inch combined wastewater sewer. Flow to Meldrum Street is captured by catch basins in the road at the Waterloo Street and Kercheval Avenue intersections.

Figure 2-5 shows the existing catch basin drainage structures in the alley. **Figure 2-6** shows a map of the existing DWSD combined sewer system near the Leib Facility site. Based on the latest survey by the Design Team, there are no direct sewer connections to either of the catch basin structures shown in the **Figure 2-5** images . It is assumed by the surveyor that the 6-inch PVC trap elbow ends in each catch basin structure lead to a blind tap into the 10-inch sewer line that runs through the alley, as shown in the **Figure 2-6**.

Drainage Structures in Alley Adjacent to Leib Facility. Catch basin north (top) and south (bottom) of TTS

Figure 2-6
Combined Sewer System Near Site of Leib Facility

3.0 System Evaluation

The drainage, paving, and security system design requirements are discussed in the following sections.

3.1 Oakwood and Leib Site Paving & Access Requirements

The proposed pavement section at both the Leib and Oakwood CSO Sites call for 9-inch-thick reinforced concrete over a minimum 8-inch thick aggregate MDOT 21AA base with HS-20 loading. Based on the recommendations provided in the geotechnical report, the existing gravel and granular fill under the gravel road at the Oakwood CSO site will be removed prior to construction of the new concrete pavement and replaced with 8" thick MDOT 21AA base. Additional MDOT 21AA gravel needs to be imported if additional unsuitable existing material is found below the proposed profile of the new concrete pavement. The proposed pavement, loading, soils were evaluated in the geotechnical report for each site, and found to be adequate to support the proposed HS-20 Loading. The proposed access roadway at the Leib Site will need to be configured to provide for 5,000-gallon tanker truck deliveries of chemical to the CSO Basin. A WB-50 design vehicle was utilized for the analysis. A service drive width of 28 feet was found to be adequate to allow for the turning movements of this design vehicle. In addition, wider radius will be provided to allow wider turns for the trucks entering driveway. **Figure 3-1** shows this analysis. The proposed access roadway at the Oakwood Site will need to be configured to provide for a boom truck with crane to remove the scrubber units at the Odor Control Facility on the north side of the site. A Terex Boom Truck was utilized for the analysis, and a concrete drive width of 16 feet was found to be adequate to allow for

the turning movements of this design vehicle. Signs will be posted along the new paved road to prevent the semi-trailers or larger vehicles from entering the paved road around the north side of the Oakwood CSO facility. In addition, bollards will be provided to prevent existing electrical vault/panels and existing structures near the new paved road. **Figure 3-2** shows this analysis.

Figure 3-1
Leib CSO Facility Proposed Access Drive – WB-50 Design Vehicle Turning Movements

Figure 3-2
Oakwood CSO Facility – Boom Truck Turning Movements

3.2 Oakwood and Leib Site Drainage Requirements

As described above, both the Oakwood and Leib CSO facilities are proposed to undergo paving projects that will introduce new impervious area to the sites. At the Oakwood facility, a paved road will replace an existing gravel road that wraps around the Oakwood screen facility, CSO basin, and odor control building. The new paved road is proposed to have the same footprint as the existing gravel road. At the Leib facility, a new paved driveway is proposed that provides access to the facility from previously vacant lots. The vacant lots are presently grass covered. The paving at Leib includes an access driveway as well as an area for three parking spaces.

Per DWSD's Stormwater Management Design Manual (2019), any development site with regulated construction activity that involves the replacement or creation of one-half acre (21,780 square feet) or more of impervious surface is subject to the Post-Construction Stormwater Management Ordinance (PCSWMO). DWSD may require that any construction activity meeting certain conditions, as specified in Section 5-63-101 in Chapter 56 Article 4 of the Detroit Municipal Code, also comply with the PCSWMO.

The Detroit Municipal Code states that the PCSWMO applies to a site if any construction activity may create a condition that would result in runoff that would:

1. Exceed the safe capacity of the receiving public sewer or body of water as determined by the Department;
2. Cause undue channel erosion;
3. Increase water pollution by scouring or transport of particulate matter;
4. Endanger property; or
5. Endanger public safety.

Figure 3-3 provides a visual flowchart for understanding the applicability of the PCSWMO.

Figure 3-3
PCSWMO Applicability Flow Chart

The additional impervious area added by the Oakwood paving project is approximately 16,400 square feet. The additional impervious area added by the Leib paving project is approximately 5,630 square feet. Neither of these sites involve the creation of greater than one-half acre of impervious area or meet the additional criteria for PCSWMO applicability. Therefore, the Oakwood and Leib sites are not required to comply with the regulatory requirements of the PCSWMO.

Although not bound by the PCSWMO, the Design Team recommends implementing stormwater runoff infrastructure guided by the PCSWMO at both the Oakwood and Leib sites to ensure proper conveyance and drainage of stormwater runoff resulting from the paving projects.

3.3 Oakwood and Leib Electrical and Security Requirements

- Gate power requirements are expected to be minimal and can be powered from the existing CSO Facility
- Parking Areas must be secured with fencing, and card readers and security cameras provided.
- Alley Encroachment Easements will need to be obtained from impacted underground utilities.
- Existing AT&T utility will need to be raised to provide clearance, and existing underground DTE electric service will need to be installed per DTE standards beneath the proposed service drive pavement.

4.0 Description of Alternatives

4.1 Oakwood Facility Site Drainage Alternatives

The site drainage alternative to support the new paving around the CSO basin focuses on improving the swales on the east and west sides of the facility. The runoff generated from the roof of the CSO basin will still be routed down the east and west sides of the building via the existing scuppers. New splash blocks located under the scuppers will catch the flow and convey stormwater directly to the newly paved road. Existing splash blocks will be replaced to assure all the drainage reaches the stormwater system. The proposed pavement design does not implement a curb on the side of the road nearest to the facility, allowing for the drainage from the splash blocks to flow over the road. The outward facing edge of the new pavement will have a shoulder. The shoulder will be graded to drain the water off the road and towards the bioswales. This design is common to both the east and west sides of the facility.

The bioswales are examples of bioretention. Bioretention practices are landscaped, shallow depressions that capture and temporarily store stormwater runoff. Runoff intercepted by the practice is then filtered through the soil (often engineered soil filter media). Bioretention practices usually consist of a pretreatment system, surface ponding area, mulch layer, soil filter media, aggregate storage layer, vegetation, and subsurface drainage system.

A drainage pipe located in the bioswale will route the collected runoff to the stormwater collection system as the swale fills. From there, the stormwater will be routed through the existing stormwater collection system on site.

Based on the recommendations provided in the geotechnical report for the Oakwood CSO site, the existing granular fill at the proposed bioswale area will be removed (minimum 18" from finished

grade of the proposed swale) and replaced with a sandy-loam or loamy-sand bioretention soil with 6% organic content and pH of 6-7.

Figure 4-1 shows plan view sketch of the proposed runoff drainage system.

Figure 4-1
Oakwood CSO Facility – Plan View of Proposed Runoff Drainage System

In addition to routing runoff over the new pavement, this design will include work to raise the rims of multiple meter and electrical vaults on the west side of the CSO basin, as well as waterproofing of the manhole chimneys. This will be done to prevent runoff from spilling into manholes and flooding the vaults.

Figures 4-2 and **4-3** show the conceptual roadway profiles and cross sections along the proposed pavement. Due to large buried electrical duct banks on the west side of the facility, underground conduits conveying flow from the roof downspouts to the proposed bio-swale were not considered feasible.

Figure 4-2
Oakwood CSO Facility – Conceptual Roadway Profile

Figure 4-3
Oakwood CSO Facility – Conceptual Roadway Cross Sections

4.2 Leib Facility Site Paving and Security Fencing Alternatives

The new access drive to the Leib Site will eliminate three existing parking spaces from the existing parking lot. These parking spaces are proposed to be relocated adjacent to the new access driveway on the lots owned by DWSD. The CS-299 report indicated that additional storage space may be desired in the future outside the existing CSO Facility, so an area for this is included in the concept plans. Two conceptual fencing alternatives were developed to provide for security and access for the newly configured service drive entrance, parking, and potential storage area. Both developed alternatives will require an existing AT&T cable to be raised to provide adequate clearance for tanker trucks using the new access drive. The existing DTE underground service lead which runs through the vacated alley will need to be field located and modified to DTE standards so it can be maintained beneath the proposed concrete pavement in the vacated alley. Subsections 4.2.1 and 4.2.2 provide a description of the alternatives analyzed by the Design Team.

4.2.1 Alternative 1 No Fencing in the Vacated Alley

This alternative proposes to install a new 30-foot-wide motorized double swing gate along the existing fence line at the point where the new service drive enters the parking lot. An interior and exterior card reader would be located on either side of the swing gate. Ideally, power would be provided by a private underground electric service from the existing CSO Facility and would need to extend across the vacated alley. A new security camera would also be installed within the parking area to monitor the relocated parking spaces and potential future storage area. The parking and storage area would be fenced and accessed by a second 30-foot-wide motorized double swing gate. Alternative 1 is presented in **Figure 4-4**

Figure 4-4
Leib CSO Facility Proposed Access Drive – Fencing & Security Alternative 1

4.2.2 Alternative 2 Fencing in the Vacated Alley

This alternative proposes to install a new 30-foot-wide motorized rolling gate approximately 50 ft to the north of the existing fence line at the point where the new service drive enters the parking lot. An interior and exterior card reader would be located on either side of the rolling gate. Ideally power would be provided by a private underground electric service from the existing CSO Facility and would need to extend across the vacated alley. A new security camera would also be installed inside the fence line to monitor the relocated parking spaces and potential future storage area. Two fenced areas of the vacated alley would have 20-foot-wide double swing gates which are normally

SERVICE DRIVE - ALTERNATIVE #2

Figure 4-5
Leib CSO Facility Proposed Access Drive – Fencing & Security Alternative 2

The Design Team developed four alternatives to facilitate drainage of runoff generated by the addition of a new driveway to the Leib CSO facility. Subsections 4.3.1 through 4.3.4 provide a description of the alternatives analyzed by the Design Team.

- Connection to DWSD Owned Sewer, Alternative 1 (Section 4.3.1)
- Connection to Toward Treatment Sewer (TTS) via Alley, Alternative 2 (Section 4.3.2)
- Connection to Onsite Stormwater System in Facility Parking Lot, Alternative 3 (Section 4.3.3)
- Surface Drainage and Bioswale, Alternative 4 (Section 4.3.4)

TM-24 Site-Civil Design.docx

Additionally, a low point will be established between the new driveway high point and the eastern edge of the alley adjacent to the Leib facility. There will be a catch basin on both the north and south edges of the new driveway at this low point. Runoff from the driveway east of the existing parking lot and west of the driveway high point will flow to this low point and be captured in the new catch basins. From here, the flow will be directed according to one of the three alternatives described in Sections 4.3.1 through 4.3.4.

This configuration of the driveway will have a slope at or near 1%. This will allow for sufficient drainage of the runoff off the driveway and will be ideal for routing the flow towards the proposed drainage structures. **Figure 4-6** shows the conceptual profile of the access drive.

Figure 4-6
Leib CSO Facility Proposed Access Drive – Conceptual Profile

4.3.1 Alternative 1 - Connection to DWSD Owned Sewer

One alternative proposed by the Design Team is to route the captured runoff from the new driveway towards an existing DWSD combined sewer in the alley located north of the facility and driveway. This would involve the installation of a new storm sewer between the catch basins in the driveway and the manhole in the northern alley. From here, the flow would join the combined wastewater effluent in DWSD's combined sewer system. **Figure 4-7** illustrates this alternative.

Figure 4-7
Plan View Sketch of the Proposed Alternative 1 Utilizing a Nearby DWSD Owned Sewer for Drainage

4.3.2 Alternative 2 - Connection to Toward Treatment Sewer via Alley

Another alternative proposed by the Design Team is to route the captured runoff from the new driveway towards the control gate chamber in the Leib facility. This would involve the installation of a new storm sewer between the catch basins in the driveway and the control gate chamber located in the alley adjacent to the Leib site. This connection would drop the flow in to the control gate chamber within the Leib Facility. From the control gate chamber, the stormwater would flow into the Toward Treatment Sewer. **Figure 4-8** illustrates this alternative.

Figure 4-8
Plan View Sketch of the Proposed Alternative 2 - Utilizing the Toward Treatment Sewer for Drainage

4.3.3 Alternative 3 - Connection to the Onsite Stormwater System in Facility Parking Lot

Another alternative proposed by the Design Team is to route the captured runoff from the new driveway towards the existing onsite stormwater system in the Leib facility parking lot. This would require installing a new section of sewer between the catch basins in the driveway and the catch basin on the north end of the facility parking lot. From here, the runoff would be integrated into the existing stormwater system and outlet via a drop manhole into the influent box at the head of the facility's S&D operations. **Figure 4-9** illustrates this alternative.

Figure 4-9
Plan View Sketch of the Proposed Alternative 3 - Utilizing the Onsite Stormwater System for Drainage

4.3.4 Alternative 4 - Surface Drainage and Bioswales

A final alternative considered the possibility of utilizing surface runoff from the newly paved road and surface draining the stormwater through bioswales adjacent to the road. This alternative was designed with minimal impact in mind. The design would allow runoff to flow off the road and into the grass lots with the bioswale improvements, increasing the infiltration capacity already present on site. Flow would be diverted off the road by paving a pronounced crown along the entire span of the access road to route sheet flow to either side. No new structures would be constructed to capture or route stormwater runoff.

This design would also allow for greater flexibility in grading the access road. Implementing curb for the road would not be an option under this alternative. **Figure 4-10** illustrates this alternative.

Figure 4-10
Plan View Sketch of the Proposed Alternative 4 – Surface Drainage and Bioswale

4.3 Alternatives Evaluation Criteria

Per Petition No. 1584 (Nov. 4, 2021) the City of Detroit reserves utility easement for the full extent of the vacated right-of-way. This easement requires ingress and egress at any time. Additionally, the standard permitting process for improvements within the limits of a vacated alley requires City Engineering permitting review and approval.

For the three parking spaces across the alley, parking lots are an allowable land use in an M3 (General Industrial) district.

The City of Detroit Engineering Division (CED) will need to approve the new driveway curb cut. The parcels 2207-2219 Meldrum St. will need to be combined and submitted for a separate Buildings, Safety, Engineering, and Environmental Department (BSEED) permit.

Outdoor storage sheds within manufacturing districts have been subject to a moratorium and most likely will require enclosure whether located on the present project site or adjacent lot. Further information about the present status of the moratorium should be confirmed with BSEED.

The design of the stormwater management systems at both the Oakwood and Leib facilities are guided by the DWSD's Stormwater Management Design Manual. Calculations of runoff flows and bioswale storage volume are developed based upon the 10-year, 24-hour storm event.

Peak runoff flow rates are calculated using the rational method. The formula for this method is seen in **Figure 4-11**. Runoff coefficients and rainfall intensity are derived from standard tables in the Stormwater Management Design Manual.

$$Q_p = CiA$$

where Q_p = Peak Flow, ft³/s
 C = Dimensionless runoff coefficient (Table 4-9)
 i = Rainfall intensity, in/hr.
 A = Drainage area, acre

Figure 4-11
Rational Method for Peak Runoff Flow Rate

Storage volume calculations for the proposed bioswales at Oakwood are also based on methodology described in the Stormwater Management Design Manual.

Sewer connections to existing DWSD owned sewers will require coordination and permitting from DWSD.

5.0 Alternatives Analysis

5.1 Oakwood Facility Roadway Geometrics and Cross-Section

The proposed Roadway cross section and width are adequate to provide for access to the Odor Control Facility. A shallow mountable curb may need to be utilized at the northwest corner of the facility where there is an existing rolling gate opening in the existing fence line.

5.2 Oakwood Facility Site Drainage

The drainage alternative at the Oakwood site will be designed with the assumption that roughly 16,400 square feet of impervious area will be added to the area surrounding the CSO Bains due to the newly paved service road. 0.1 cfs of additional runoff generated from the new paving over the existing gravel road will be considered when designing the stormwater management system.

To meet PCSWMO standards, the bioswales on either side of the CSO basin will be sized to manage the 10-year, 24-hour storm event. The bioswales on both sides of the basin will be sized to store the computed stormwater runoff for the associated drainage area.

Routing the CSO basin roof drainage over the road and shoulder has the benefit of requiring no additional structures to route the flow across the road.

The disadvantage of this alternative is that the road must be designed to accommodate runoff passing across it and must prevent water from becoming stagnant on the road. This alternative presents more limitations on the design and grading of the new paved road.

5.3 Leib Facility Fencing and Access

5.3.1 Alternative 1 - No Fencing in the Vacated Alley

The benefit of this alternative is that it allows free access to other utilities which presently occupy the vacated alley including AT&T communications lines, the buried DTE Electric Service, and the buried DWSD sanitary sewer. The disadvantage of this alternative is that swing gates need to be utilized at the existing fence line due to the limited clearance around the existing DTE transformer to allow for a roll gate which is what is preferred by GLWA. Another disadvantage is that a second set of swing gates would need to be maintained and used to access the relocated parking spaced on the DWSD owned lots. If additional parking spaces are required, a roll gate fencing configuration would need to be implemented on the lots owned by DWSD.

5.3.2 Alternative 2 - Fencing the Vacated Alley

The benefit of this alternative is that only one gate is needed to provide security and access to the new concrete access drive and relocated parking spaces. A roll gate across the access drive entrance can be provided in this arrangement because there are no clearance restrictions as it is located away from the existing fence line and existing DTE transformer. The disadvantage of this alternative is the normally locked swing gates providing shared access to other utilities restrict their access more than Alternative 1. Additionally, a fence across the vacated alley may present another issue with regard to permit approval from the City of Detroit.

5.4 Leib Facility Site Drainage

All alternatives will be analyzed with the assumption that roughly 5,630 square feet of impervious area will be added to the Leib facility site because of the implementation of the new driveway and three parking spaces. For Alternatives 1-3 discussed in Sections 4.3.1 through 4.3.3, the runoff generated will be considered when designing the new sewer system.

5.4.1 Alternative 1 - Connection to DWSD Owned Sewer

The connection to the existing DWSD combined sewer has the benefit of using an existing outlet near the site. It also has the benefit of requiring the shortest length of additional sewer compared to the next three alternatives.

This alternative has the disadvantage of requiring permitting from DWSD to tie into their sewer. Additionally, the DWSD sewer services homes in the area. Adding storm flow to the combined sewer raises the concern of increasing the peak hydraulic grade lines in this sewer during large storm events. DWSD stormwater permitting staff provided indications that they had no concerns with tapping the rear yard sewer at this location. Staff indicated a connection directly to an existing manhole structure or a blind tap to the existing sewer is permissible. Another disadvantage to this alternative is that this route would cross an existing electrical duct bank owned by DTE.

5.4.2 Alternative 2 - Connection to Toward Treatment Sewer via Alley

The connection to the TTS also has the benefit of using an existing outlet near the site. The TTS is already used as an outlet for the runoff generated over the grass paver and roof on the south side of

the facility and adding additional flow to this sewer should pose no issues. This alternative would also feature an additional one or two catch basins in the alley between the facility and the vacant lots. This would provide the added benefit of improving drainage in the alley.

This alternative has the disadvantage of requiring the construction of more structures compared to the other alternatives.

5.4.3 Alternative 3 - Connection to the Onsite Stormwater System in Facility Parking Lot

The connection to the onsite stormwater sewer system has the benefit of integrating into the already existing stormwater management system on site. The additional runoff added to the outlet at the head of the facility should pose no conveyance issues.

This alternative has the disadvantage of requiring a large section of the existing parking lot to be demolished and repaved to lay out the new sewer line and connect to the existing sewer system. This sewer alternative would also route through a DTE easement, which would require going through a DTE release of ROW process.

5.4.4 Alternative 4 – Surface Drainage and Bioswales

Allowing runoff from the new access road to freely flow onto the grassy lots and into bioswales has the benefit of not requiring the construction of new structures to capture and convey stormwater flow. Additionally, the expected runoff generated by the new driveway is expected to be minimal. This alternative does not provide the direct drainage that the prior three alternatives provide. However, this alternative does promote positive drainage from the vacant lot areas surrounding the new driveway. Overall, the installation of bioswales is expected to capture the runoff from the new driveway and improve the drainage in the vacant lots.

6.0 Life Cycle Cost Analysis

Not used.

7.0 Summary, Recommendations, and Key Decisions

Leib Site

The Jacobs CS-299 report estimated the construction cost for a new access drive and cantilever gate at the Leib Site of \$138,000. This cost did not include relocated parking spaces, underground drainage, or security fencing for the new access drive. The recommended alternatives will increase the estimated construction costs at this site.

Fencing Alternative 2 is recommended. This alternative provides secure access to the Owners' facilities with one rolling gate, and two normally locked swing gates for shared access where proposed fencing crosses the vacated alley. The rolling gate would be similar to the one which is presently in use at the site and meets the Owners (GLWA) security standards. The design team will coordinate with GLWA security staff to ensure the proposed improvements meet GLWA security standards. This alternative would be easier for the Owner to operate and maintain and provides

space for additional parking spaces to be added should this be required in the future. Shared access to utilities in the vacated alley is also provided for.

The preferred drainage alternative at the Leib site is Alternative 4 which allows runoff to flow across the driveway and into bioswales adjacent to the new driveway. This alternative does not require the construction of any additional structures on the site.

This alternative has the benefit of utilizing green infrastructure to infiltrate the runoff generated by the new driveway. There is little concern of the bioswales being able to capture the entirety of the runoff due to the small volume of runoff generation expected from the implementation of the new driveway. This alternative also has the benefit of avoiding crossing or connecting to other existing utilities on the site. Drainage Alternative 4 is also likely to be the least expensive alternative.

Oakwood Site

The CS-299 Report estimated the construction cost for a new concrete access drive and drainage at the Oakwood Site at \$497,000. The recommended alternative at this site includes the items considered in the CS-299 cost estimate.

The preferred drainage alternative at the Oakwood site is to route CSO basin roof drainage over the newly paved road. This alternative has the benefits of requiring no additional structures to route the flow across the road and being easier to maintain than an underground system. This alternative also avoids conflicts with existing utilities on the west side of the CSO basin.

The installation of improved bioswales on both the east and west sides of the CSO basin would complement this design for either routing alternative chosen. The bioswales will be sized to provide retention of the runoff generated at and around the CSO basin.

7.1 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

7.1.1 Leib Site

- For Leib site drainage, GLWA is against the implementation of drainage infrastructure. Instead, GLWA prefers that the Design Team utilizes drainage swales and the existing drainage system for the recommended alternative.
- For Leib site, GLWA prefers the Alternative 2 Fencing in the Vacated Alley. This alternative proposed 30 ft wide motorized rolling gate, an interior and exterior card reader, a new security camera, and 2-20 ft wide swung gates with lock for utility access, bollard for protection of transformer.

7.1.2 Oakwood Site

- For Oakwood CSO Facility, GLWA prefers the improvements including a paved road with shoulder on one side, bollard to protect electrical vault and other structure along the paved road, signs for semi-trailers, and waterproof covers/rims for existing manholes.

8.0 Next Step

This section provides a list of additional investigations to be performed to support the final recommendations for each alternative that will proceed into detailed design, or additional information and coordination needs for early in detailed design for advancement of this task.

- The design team will have to coordinate with Jonathan Farrugia to replace damaged concrete drive and sidewalk at the Oakwood CSO facility.
- The design team will discuss the quantities and unit prices of the base material with GLWA during design phase.
- During detailed design, truck turning analysis will be performed with a wider turning radius at the proposed driveway at the Leib CSO facility to provide sufficient clearance for the trucks and ensure no damage to the proposed improvements and ground.
- The grades and cross-section details of the proposed bioswale at the Oakwood CSO facility will be provided during design phase.
- During design phase, team will coordinate with GLWA security to ensure the proposed improvements meet GLWA standards.

2.2 Architectural, Plumbing, and HVAC, TM-8 and TM-9

Leib SDF

- Removal and reinstallation of chemical facility wall to accommodate hypo storage tank replacement
- Wall modification, door removal and new double door for SF-1 access
- East and West vestibule modifications for NFPA 820 area isolation
- Potential modifications to the chemical storage/feed room (TBD)
- New thermostat in office
- Floor drain modification in garage

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Dan Martel, METCO
Pulanith Egodaheewa, METCO*

Date: June 1, 2023

*Subject: TM-8 Leib HVAC Improvements
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) has been developed to address two of the HVAC related issues at the Leib CSO Screening and Disinfection Facility (SDF) identified as part of the Leib HVAC-1 task and identified in the CS-299 Report. The memo reviews the existing built conditions related the maintenance accessibility for the supply fan SF-1 and the temperature controls for the Office (Control Room). Based on the Design Team's evaluations discussed in this TM, the Design Team is recommending the following for the two HVAC related issues.

- To provide more adequate maintenance access to the supply fan (SF-1), the Supply Fan Room shall be enlarged by creating an opening in the east wall of the room, and adding a room extension with a ceiling, and adding a set of double exterior doors to allow for future replacement of SF-1.
- For the Office HVAC system temperature controls issue noted in the scope of work, it was determined through review of the CIP No. 260611, Great Lakes Water Authority (GLWA) Contract No. 1803718, Leib Combined Sewer Overflow (CSO) SDF HVAC Improvements, completed in 2021, that the temperature controls have already been separated from the Toilet and Jan Room, and the Sampler Room. However, according to discussions with the Operator, the Design Team recommends to replace the existing wall mounted thermostat that does not have a temperature readout screen, with a similar model that includes the LCD for displaying the temperature.

1.0 Introduction and Purpose

GLWA CSO Facilities Improvements Project – Contract No. 2101475 - Leib HVAC-1 Task requires the Design Team to review the issues related to the Leib facility's existing HVAC system as identified in the CS-299 Report. Two issues from the report were identified for review, analysis, and evaluation for implementation in to the GLWA CSO improvements Project.

1. The lack of maintenance access to the Supply Fan SF-1, located in the Supply Fan Room that supplies ventilated fresh air to the Screening and Disinfection area below grade. The size of the SF-1 unit and its physical position in the Supply Fan Room only allows for less than 12 in. of maintenance clearance on the east side of the room to maintain the supply fan's belt, sheeves, motor, and grease fittings.
2. The HVAC system temperature controls for room Office. The referenced CS-299 Report identified improvements that have been made to improve operator comfort, however, the Office HVAC system is still shared with Toilet and Jan Room, and Sampler Room. The report indicated that separate temperature controls are desired for the Office.

2.0 Existing System(s) Description (and/or Conditions)

Descriptions of the existing systems and conditions related to the two issues, lack of maintenance access to the Supply Fan SF-1, and HVAC system temperature controls for the Office are noted in Section 2.1.

2.1 Supply Fan SF-1 Lack of Maintenance Clearance in Supply Fan Room

Supply fan SF-1 for the Leib CSO SDF is located in the Supply Fan Room and supplied fresh air to the Screening and Disinfection area below grade through a below grade concrete duct/pipe connected to the metal supply ductwork in the Screening and Disinfection space. The supply fan pulls air from the air intake R13 – Plenum room to the west of the Supply Fan Room. The Supply Fan Room is considered by NFPA 820 as a Class 1, Division 1 hazardous classification space due to the room's connectivity to the Screening and Disinfection space below that also has the Class 1, Division 1 hazardous classification. The room has an open ceiling to the trussed roof system above, but is physically separated from all other spaces on the main level with continuous walls that separates the attic space, and precast concrete ceiling over spaces within the connected attic space. See **Figure 2-1**.

The current position of the supply fan SF-1 only allows for limited access to the maintain the supply fan's belt, sheeves, motor, and grease fittings. The position of the supply fan is dictated by the location of the concrete duct that it connects to, which appears to be shifted too far east to allow for suitable maintenance access on the east side of the room. **Figure 2-2** shows the limited access space.

Figure 2-1
Supply Fan Room Plan Showing Adjacent Rooms and Physical Separation Method.

Figure 2-2
Northeast Corner of Supply Fan Room Showing Minimal Maintenance Access for SF-1.

2.2 Office HVAC System Temperature Controls

The Office HVAC system was originally installed under Detroit Water and Sewerage Department (DWSD) Contract PC-732 – Leib CSO SDF, and completed in 2004. The HVAC system for the Office consists of unitary split AC unit (Trane 4TXCB003DS3HCAA indoor unit and 2 Ton nominal capacity TTB024C100A outdoor condensing unit) and a natural gas fired furnace unit (Trane TUD1B080A9361BB) which has 80MBH input and 64 MBH output heating capacity. This single stage heating and cooling up-flow air handling unit has 766 CFM airflow. Supply and return ducts run directly to the Office with supply diffuser and return grille in the acoustical drop ceiling.

The Office HVAC system controls were recently upgraded under the CIP No. 260611, GLWA Contract No. 1803718, Leib CSO Facility HVAC Improvements, completed in 2021. The controls were updated to connect to a new HVAC control panel with BACnet MSTP control panel that adjusts the room temperature set points based on the user's definable schedule to determined Occupied Mode or Unoccupied Mode.

- Occupied Mode: The unit shall maintain 75 deg. F. (adjustable) cooling setpoint and a 68 deg. F. (adjustable) heating setpoint. The occupant shall be able to adjust the zone temperature heating and cooling set points at the zone sensor.
- Unoccupied Mode: The unit shall maintain 85 deg. F. (adjustable) cooling setpoint and a 55 deg. F. (adjustable) heating setpoint to achieve night setback temperature.

While the CS-299 Report indicates that Office's HVAC system also services the Toilet and Jan Room and Sampler Room, the current HVAC-1 unit only provides conditioned air to the Office. (**Figure 2-3**) The controls for the Office are already separated from other spaces, allowing the operator to adjust the temperature to their desired setting while the room is occupied.

Figure 2-3
HVAC Plan M-100 from GLWA Contract No. 1803718, Leib CSO Facility HVAC Improvements showing dedicated HVAC unit for Office.

3.0 Evaluation

Evaluation of the existing systems and conditions related to the two issues, lack of maintenance access to the supply fan SF-1, and HVAC system temperature controls for Office are noted in Section 3.1.

3.1 Supply Fan SF-1 Lack of Maintenance Clearance in R9 – Fan Room

Evaluation of the supply fan SF-1 maintenance requirements listed in the Leib CSO SDF Operation and Maintenance Manual calls for maintaining the grease bearings, inspection of all bolts and screws, inspection of the belt, and a recommended dismantling and checking of the motor. The maintenance schedule taken from the manual is shown in **Table 3-1**.

Table 3-1 Supply Fan SF-1 Maintenance Schedule

Frequency	Item	Maintenance and Operation Task
Bi-monthly	Fan	1. Grease bearings
Semi- annually	Fan and Motor	1. Inspect bolts and screws. 2. Inspect belt. 3. Inspect for cleanliness.
Every 3 years	Motor	1. Recommended to pull apart. 2. Check and re-grease bearings

Note: Taken from Table 12-1 Maintenance and Operations Schedule

Additional maintenance recommended for centrifugal fans include:

- When inspecting bolts and screws, tighten if necessary.
- When inspecting the belt, check the tension of belt to meet manufacturer's requirements.
- Inspect bearings for excessive vibration, wear, and overheating.
- Check impeller and housing for build-up of foreign parts and/or overheating.
- Check sheaves for worn grooves or other damage, and for cleanliness. Replace as needed.

Typical required maintenance clearances needed for inspection and maintenance of the fan unit is 30 to 36 in. The current maintenance clearance provided between the motor housing and the north wall is about 24 in., while the maintenance clearance between the fan belt guard and the east wall is only about 6 in. While the 24 in.-clearance between the north wall and the motor housing is less than desired, the clearance is enough to allow for maintaining the motor under less-than-ideal clearance conditions. The 6 in.-clearance between the belt guard and the east wall is not suitable for maintaining the belt and proper inspection of the fan unit, belt, and sheaves.

3.2 Office HVAC System Temperature Controls

The current controls for the HVAC-1 unit servicing the Office provide the dedicated temperature control noted to be evaluated and modified as part of Leib HVAC-1 Task. Heating and cooling setpoints are adjustable, but are set up for efficiency to reduce the heating and cooling requirements during the evening when the facility is typically unoccupied.

During a site visit, the Design Team interviewed the Operator regarding the environmental conditions of the Office. The Operator indicated that the temperature level was fine, and felt that no adjustments were needed. The Operator showed the Design Team that they could press up or down on the button on the wall-mounted thermostat to raise or lower the temperature. **Figure 3-2** shows an image of the wall mounted thermostat.

Figure 3-2
Adjustable Wall Mounted Thermostat.

Further discussions with the Operator indicated that they were not able to see the temperature of the room in the Ovation SCADA system. This is confirmed by the GLWA Contract No. 1803718, Leib CSO Facility HVAC Improvements As Built Drawings, dated March 15, 2021. Sht. M-502 shows the requirement for temperature and temperature alarm monitoring through the existing Ovation SCADA system has been crossed out. The HVAC-1 unit is connected to a BACnet MSTP control panel and Jace controller that connects to a PC running the BACnet software to monitor and control the unit's settings, varying temperature points, and alarms.

4.0 Description of Alternatives

Alternatives that address the two issues, lack of maintenance access to the supply fan SF-1, and HVAC system temperature controls for the Office are discussed in this section.

4.1 Supply Fan SF-1 Maintenance Access

As part of the scope of the Leib HVAC-1 Task, The Design Team is tasked to resolve the maintenance access issues with supply fan SF-1. The CS-299 Report provided an evaluation of an approach that relocated the east wall of the Supply Fan Room that is shared with the Garage. Additional alternatives for providing maintenance access are also discussed in this section.

4.1.1 SF-1 Maintenance Access Alternative 1 - Enlarge Room by Moving the East Wall of Supply Fan Room:

To provide the maintenance access to the supply fan SF-1, a possible solution previously explored as part of the CS-299 Report was to enlarge the room by demolishing the east wall of the room and

constructing a new wall within the footprint of the Garage to provide the needed maintenance clearance. With the north side the fan's motor support skid less than 16 inches (motor housing about 24 inches) from the north wall, access to the enlarged maintenance area would require and an added man-door access to the exterior north wall. **Figure 4-1** shows a plan for the relocation of the Supply Fan Room east wall. Additional considerations include the current use of the space in the Odor Control Room (Garage) as an area for storage. **Figure 4-2** shows an image of the Garage space where the proposed wall would be relocated.

Alternative 1 modifications include the following:

- Shutdown of SF-1 temporarily for work for an extended period requiring temporary ventilation.
- Protect SF-1 during demolition work.
- Demo and remove 12-in. CMU wall that extends to the bottom of the sloped roof deck. This will require review from a Structural Engineer to confirm that the wall is not supporting any loads. The clear span roof truss appears to be supporting the roof deck.
- Items to be rerouted/relocated on north and west walls of the Garage
 - Sanitary vent pipe that runs through the roof.
 - Cold water piping.
 - Fire sprinkler riser and backflow preventer and associated piping.
 - Fire alarm system strobe device, associated conduit and wiring.
 - Conduit and wire with an unidentified pullbox.
 - Wall receptacles with associated conduit and wiring.
 - Disconnect switch for the air compressor located nearby.
 - Wall switch for lights above.
 - Partial of ductwork in the northwest corner, and relocation of supply grille.
 - Relocate hung lights in the Garage, and add additional lighting inside the Supply Fan Room extension and at the exterior door.
 - The floor drain in NW corner of the Garage will be relocated. Cannot be connected to the floor drain system in the Garage that remains, as this would violate NFPA-820 physical separation requirements.
- Sawcut and remove existing floor slab in the Garage to place new reinforced concrete foundation grade beam. Grade beam would be two ft 6-inch-wide and constructed to a depth of 5 ft, 9 in. below top of floor slab to match existing conditions under the existing wall being removed. Replace slab that was removed.

- Construct new 12 in. CMU wall to the underside of the roof deck located 4 ft from the existing location to allow for a new 36 in wide door into expanded room Supply Fan Room for maintenance access to the east side of SF-1.
- Clean entire Supply Fan Room space.
- Paint walls and ceiling. Touch-up paint all ferrous metals.
- Add additional storage racks as needed.
- Perform needed maintenance and inspections.

Figure 4-1
Leib CS SDF Removal of Supply Fan Room east wall and construct new east wall – Alternative 1.

Figure 4-2
Leib CSO SDF – north-west corner of Garage area

4.1.2 SF-1 Maintenance Access Alternative 2 - Enlarge Room by Creating an Opening in the East Wall of Supply Fan Room, and Adding Room Extension with Ceiling:

To provide the maintenance access to the Supply Fan SF-1, a possible solution would be to enlarge the room by opening the east wall of the room and constructing a new shorter wall with a ceiling deck within the footprint of the Garage to provide the needed maintenance clearance. The room extension would be enlarged only enough to provide the needed clearance, and avoid relocation of critical fire protection and domestic water systems. The newly constructed room extension could be constructed of 8-inch-thick CMU, with a new ceiling deck at about 10 ft above the finished floor.

Figure 4-3 shows the room extension of the Supply Fan Room through the east wall.

While similar in footprint to Alternative 1, this alternative would avoid the need for deep large foundations, where a thickened slab could be used, and avoids the difficult masonry work of coping around roof truss members and bridging. This alternative does require a new structural beam be installed in the mating wall for the Supply Fan Room and the Garage, which will require structural design and evaluation. To allow for replacement of SF-1 in the future without temporary shoring and removal of walls, a set of double doors sized to allow for the removal of SF-1 is included in the design. Additional considerations include the current use of the space in the Garage as an area for

storage. **Figure 4-3** show an image of the Garage space where the proposed wall would be relocated.

Alternative 2 modifications include the following:

- Shutdown of SF-1 temporarily for work.
- Protect SF-1 during demolition work.
- Temporarily shore 12" CMU wall to allow for new beam to be installed to create new opening in the wall.
- Demo and remove portion of 12 in. CMU wall below the new beam.
- Temporarily shore exterior bearing wall to allow for new lintel to be installed over new opening in the wall for a set of double doors.
- Items to be rerouted/relocated on north and west walls of the Garage.
 - Sanitary vent pipe that runs through the roof.
 - Fire alarm system strobe device, associated conduit and wiring.
 - Conduit and wire with an unidentified pullbox.
 - Wall receptacles with associated conduit and wiring.
 - Disconnect switch for the air compressor located nearby.
 - Wall switch for lights above.
- Relocate hung lights in the Garage, and add additional lighting inside the Supply Fan Room extension and at the exterior door.
 - The floor drain in NW corner of the Garage will be relocated. Cannot be connected to the floor drain system in the Garage that remains, as this would violate NFPA-820 physical separation requirements.
- Sawcut and remove existing floor slab in the Garage to place new thickened concrete slab to support shorter wall and tributary width of ceiling deck. Thickened slab would be 2- ft-wide at the bottom and angle up to the underside of existing 10-inch slab thickness, and be an extra 9 in. thicker than the slab to match the existing thickened slab details for similar configurations at the station.
- Construct new 8 ft CMU wall to a height of 8 ft, 8 in., with a new light gauge joists framed ceiling deck with $\frac{3}{4}$ rated plywood decking, and gypsum boards ceiling covering in the Supply Fan Room. This will allow for an open deck that can be used for storage in the Garage.
- Install new doors.
- Clean entire Supply Fan Room space.

- Paint walls and ceiling, existing roof structure if needed. Touch-up paint all ferrous metals.
- Add additional storage racks as needed.
- Perform needed maintenance and inspections.

Figure 4-3
Leib CSO SDF – Removal of Supply Fan Room east wall and construct new east wall – Alternative 2.

4.1.3 SF-1 Maintenance Access Alternative 3 - Reposition the Existing SF-1 to Allow for Additional Maintenance Access:

To provide the maintenance access to the supply fan SF-1 and limit the encroachment on the Garage and the rerouting of piping and ductwork associated with the previously discussed Alternatives 1 and 2, repositioning the SF-1 supply fan was explored. The position of the supply duct pipe that penetrates the floor has dictated the position of SF-1 fan unit, with the supply discharge of the fan directly over the top of the pipe penetration. There is room however to lift up the supply fan unit and skid and shift to the west wall to provide the needed clearance on the east side of the fan unit at the belt, motor, and sheeves.

To accomplish this, the fan unit would need to be lifted and shifted approximately 30 in. The supply air intake opening into the Plenum Room is an 80" square opening that can be lifted 24 in. with 16

in, left for a new lintel to support the precast concrete ceiling deck of the plenum room. The fan unit skid would need to be supported on vibration isolators bearing on a new structural steel frame and posts to support the skid. To allow for clearance in front of the existing door, the fan's skid would need to be cut short, and with the structural support also designed to allow for the needed clearance in front of the door. The supply discharge of the fan unit would then connect to an angled duct section with a flexible connector. The angled duct section would then connect to the existing transitional duct section stubbing out of the duct pipe. Additionally, to provide better access to the east side of the fan unit, a new exterior door wall be added on the north wall at the east end of the wall, providing the needed access. **Figure 4.4** shows a plan showing the proposed modifications. **Figure 4.5** shows a sectional sketch showing the existing position and **Figure 4.6** shows a sectional sketch showing the proposed repositioning.

Alternative 3 modifications include the following:

- Shutdown of SF-1 temporarily for work.
- Disconnect SF-1 from supply and discharge ductwork.
- Temporarily shore R8-Plenum room precast concrete ceiling to allow demo of CMU wall at opening.
- Add new lintel and reposition opening.
- Modify existing skid to allow for clearance in front of the door.
- Temporarily lift SF-1 to assemble and install new structural steel support frame.
- Place SF-1 on the support frame, replace vibration isolators.
- Relocate controls and explosion proof enclosures as needed.
- Add new door and door opening in the exterior wall.
- Install new duct sections for connection to Plenum Room and the supply discharge ducts with new flexible duct connectors.
- Perform needed maintenance and inspections.

Leib CSO SDF – Repositioning of supply fan SF-1– Alternative 3.

Figure 4-5
Leib CSO SDF – Sectional View of SF-1 – Existing Position.

Figure 4-6
Leib CSO SFD – Sectional View of SF-1 – Repositioned

4.2 R1 – Office HVAC System Temperature Controls

As part of the scope of the Leib HVAC-1 Task, The Design Team is to improve the Operator's comfort level and provide separate temperature controls for the Office. As noted above in the Section 2.2 – Office HVAC System Temperature Controls, the Office currently has controls separate from the Toilet and Jan Room. and the Sampler Room. The recent upgrade to the HVAC controls completed in 2021 under the CIP No. 260611, GLWA Contract No. 1803718, Leib CSO SDF HVAC Improvements, has provided the dedicated controls and control of the Office temperature by using the wall mounted adjustable thermostat. Alternatives discussed in this section include leaving the system as is with the dedicated controls, or replacing the wall mounted adjustable thermostat with a wall mounted adjustable thermostat that includes a digital temperature readout.

4.2.1 Office HVAC System Temperature Controls Alternative 1 – Leave As Is:

With the temperature controls for the Office already dedicated to that room only, no further work related to these HVAC Controls is required under the scope of the Project. The Design Team would recommend that the HVAC Control setpoints, monitoring points, and occupied/unoccupied schedule are reviewed with the Operator, and adjustments be made accordingly using the BACnet connected system.

4.2.2 Office HVAC System Temperature Controls Alternative 2 – Replace Wall Mounted Thermostat:

As noted above, with the temperature controls for the Office already dedicated to that room only, no further work related to these HVAC Controls is required under the scope of the Project. However, per the noted interview with the Operator, the desire to know the temperature of the room and make adjustments as needed exists. To allow this added monitoring, the wall mounted thermostat can be replaced with same NS Series type sensor, but with a model that offers a LED display that allows the user to view zone temperature, relative humidity, and CO2 monitoring, with functionality of adjusting setpoints if needed. This replacement will not alter the current monitoring and control thru the BACnet MSTP control panel and Jace controller connected to a PC running the BACnet software.

4.3 Evaluation Criteria and GLWA Input when discussing alternatives.

4.3.1 Evaluation Criteria:

The above noted SF-1 related alternatives will be analyzed in the subsequent section using the following criteria.

- Improved Operation and Maintenance
- Costs

The above noted Office Temperature Controls related alternatives will be analyzed in the subsequent section using the following criteria.

- Improved Comfort Level
- Costs

4.3.1 GLWA Input:

During the Design Team's site visit to the Leib facility, The Design Team discussed Alternatives 1 and 2 with the facility's Operator who had concerns mostly about loss of space for storage in the Garage.

The operator also discussed a functionality issue with the operation of the supply fan SF-1. Prior to a recent upgrade, if there was a scheduled visit that required entry into the Screening and Disinfection area, which SF-1 supplies fresh air to, then the Operator would be able to press a "START" button located in the West Vestibule. The recent upgrade has reconfigured the controls so that SF-1 will start only after an occupancy sensor that turns the lights on to stairwells senses movement. The Operator would like the ability to start the SF-1 with a push button, rather than relying on the stairwell occupancy sensor.

5.0 Alternatives Analysis and Evaluation

To analyze the alternatives noted above for the two Leib HVAC-1 task issues, each alternative is analyzed for advantages and disadvantages listed, and evaluated based on the evaluation criteria for each issue.

5.1 Supply Fan SF-1 Maintenance Access Alternatives

The three alternatives to be analyzed and evaluated for supply fan SF-1 maintenance access are discussed in this section.

5.1.1 SF-1 Maintenance Access Alternative 1 - Enlarge Room by Moving the East Wall of Supply Fan Room – Advantages and Disadvantages:

Advantages:

- Provides the needed maintenance access for SF-1.

Disadvantages:

- Many items identified to be relocated, including fire main and possibly water BFP lineup.
- 12 in. CMU wall will require larger foundations to be constructed vs. Alternative 2
- 12 in. CMU wall difficulties coping around roof truss members and bridging.
- Loss of valuable floor space in garage currently being used for Storage.

5.1.2 SF-1 Maintenance Access Alternative 2 - Enlarge Room by Creating an Opening in the East Wall of Supply Fan Room, and Adding Room Extension with Ceiling – Advantages and Disadvantages:

Advantages:

- Provides the needed maintenance access for SF-1.
- Limits added foundations to thickened slab only.

- Limits difficult overhead masonry work to cope around roof truss members.
- Allows existing ductwork in Odor Garage to remain in place without modification.
- Allows fire main and BFP lineup in Garage to remain in place without modification untouched.

Disadvantages:

- Many items identified to be relocated (less HVAC duct, fire main, BFP lineup, compared to alternative 1)
- Need to add beam for opening in the 12 in. CMU east wall
- Loss of valuable floor space in garage currently being used for Storage, takes up 8-inch- wider space.

5.1.3 SF-1 Maintenance Access Alternative 3 - Reconfigure the Existing SF-1 to Allow for Additional Maintenance Access – Advantages and Disadvantages:

Advantages:

- Provides the needed maintenance access for SF-1.
- Leaves the existing storage area in the Garage alone.
- Relocation of several pipes and conduits along the shared wall with the Garage is not needed.
- Limits demo work of CMU walls to only repositioning opening through wall shared with Plenum Room.
- Limits difficult overhead masonry work to cope around roof truss members.
- Allows existing ductwork in Garage to be untouched.

Disadvantages:

- Limited space in Supply Fan Room to work and lift the fan unit.
- While maintenance access is improved. Some maintenance locations will be elevated, possibly requiring a step stool.
- Relocation of electrical enclosures needs to be reviewed further to ensure NEC required clearances are met.

5.1.4 SF-1 Maintenance Access Alternative Evaluation:

Table 5-1 Supply Fan SF-1 Maintenance Access Alternative Evaluation:

Alternative	Improved Operation and Maintenance Access: 1-5	Costs: 1-5	Total Score: 1-10
Alternative 1 - Enlarge Room by Moving the East Wall of Supply Fan Room	5	2	7
Alternative 2 - Enlarge Room by Creating an Opening in the East Wall of Supply Fan Room, and Adding Room Extension with Ceiling	5	4	9
Alternative 3 - Reconfigure the Existing SF-1 to Allow for Additional Maintenance Access	4	4	8

Based upon the alternative evaluation, Alternative 1 should be eliminated from consideration based on the costs being excessive related to the other two alternatives, which provide similar or equal improvement to operation and maintenance access.

5.2 Office HVAC System Temperature Controls

The two alternatives to be analyzed and evaluated for the Office HVAC System Temperature Controls discussed in this section.

5.2.1 Office HVAC System Temperature Controls Alternative 1 – Leave As Is – Advantages and Disadvantages:

Advantages:

- No further Costs
- Dedicated controls remain for the Office HVAC System

Disadvantages:

- Operator unable to confirm actual temperature in Office.

5.2.2 Office HVAC System Temperature Controls Alternative 2 – Replace Wall Mounted Thermostat – Advantages and Disadvantages:

Advantages:

- Operator able to confirm actual temperature in Office.
- Operator able to make adjustments to setpoints if allowed on thermostat.
- Dedicated controls remain for the Office HVAC System

Disadvantages:

- Additional Costs
- Setpoint adjustments by the Operator may not be desired by GLWA.

5.2.3 Office HVAC System Temperature Controls Alternative Evaluation:

Table 5-2 Office HVAC System Temperature Controls Alternative Evaluation:

Alternative	HVAC Controls Accessibility: 1-5	Costs: 1-5	Total Score: 1-10
Alternative 1 – Leave As Is	1	5	6
Alternative 2 – Replace Wall Mounted Thermostat	2	4	6

Based upon the above alternative evaluation, both alternatives should be reviewed with GLWA to confirm whether replacement of the existing wall mounted thermostat would be a benefit to the operations of the facility, and comfort level of the Operator.

6.0 Summary and Recommendations

Section 7.0 provides a summary and recommendations for the two HVAC issues, lack of maintenance access to the Supply Fan SF-1, and HVAC system temperature controls for Office discussed in this TM-8.

6.1 Supply Fan SF-1 Maintenance Access

For the supply fan SF-1 maintenance access issue noted in the scope of work as part the Leib HVAC-1 Task, three alternatives were described, evaluated, and analyzed above. As noted in the Leib HVAC-1 Task requirements one of the alternatives was taken from the CS-299 Report. As determined in the CS-299 Report, the cost associated with relocating the entire CMU wall, which extends to the bottom of the sloped roof deck, the additional requirements for relocating critical fire protection and domestic water services, and the requirement for a deeper foundations would outweigh the benefit gained versus the other two alternatives. Costs noted to relocate the wall in the CS-299 Report from 2021 were estimated at \$126,000.

Alternative 2 enlarges the Supply Fan Room to provide access similar to Alternative 1, but limits demolition of the wall, eliminates relocation of the fire main and BFP lineup, and limits the volume displaced in the Garage. Alternative 3 repositions the supply fan SF-1 inside the Supply Fan Room to allow for needed access. Both of the Alternatives 2 and 3 are feasible, however Alternative 2 allows for the needed access without raising the maintenance location points to require a step stool. Alternative 3 would also require modification of the existing equipment skid, which would likely result in an atypical fan unit installation. This would lead to additional modification of the skid when the fan unit is eventually replaced. In addition, the electrical enclosure required NEC clearance would need to be resolved. Alternative 2's main disadvantage is the loss of space used for

storage in the Garage. The Design Team would recommend that the stored materials and equipment be reviewed and evaluated for continued storage at the facility, and a layout of the space that better organizes the stored materials can be developed to assist in this review and evaluation, for adding additional storage racks as needed.

The Design Team's recommendation is to proceed with preliminary design with the modifications described in SF-1 Maintenance Access Alternative 2 to enlarge the room by creating an opening in the east wall of supply fan room, adding a room extension with a ceiling that can be designed to offer space for elevated storage in the Garage as well , and adding a set of double exterior doors to allow for future replacement of SF-1.

6.2 Office HVAC System Temperature Controls

For the Office HVAC system temperature controls issue noted in the scope of work, it was determined through review of the CIP No. 260611, GLWA Contract No. 1803718, Leib CSO Facility HVAC Improvements, completed in 2021, that the temperature controls have already been separated from the Toilet and Jan Room, and the Sampler Room. The Design Team's site visit and interview determined that the Operator would like the ability to see the temperature in the Office. The Design Team recommends to replace the existing wall mounted thermostat that does not have a temperature readout screen, with a similar model that includes an LCD for displaying the temperature.

6.3 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

6.3.1 SF-1 Maintenance Access:

- Add a set of double doors to the exterior wall of the Supply Fan Room to allow for the removal of SF-1 in the future, as discussed in the TM Workshop.
- Alternate 2 - Enlarge Room by Creating an Opening in the East Wall of Supply Fan Room, and Adding Room Extension with Ceiling was selected during the TM Workshop as the best alternate. This alternate has been revised to include the double doors requested during the Workshop.
- The existing floor drain in the Garage located in the footprint of the Supply Fan Room extension shall be relocated and not abandoned per direction from GLWA provided in the review of the Draft TM-08.

6.3.2 Office HVAC System Temperature Controls:

- Alternate 2 - Replace Wall Mounted Thermostat was selected during the TM Workshop as the best alternate.

7.0 Next Steps

This section provides a list of items which require advancement/further development as the design process advances for the two recommended paths previously discussed for providing additional maintenance access to the Supply Fan SF-1, and modifying HVAC system temperature controls for Office.

7.1 Supply Fan SF-1 Maintenance Access Room Extension with Ceiling

- Further detailed review of items listed to be relocated. Adjustments to the width and height of the opening can be made to further limit needed relocations.
- Recommended survey of existing stored materials, and planned organized layout for storing materials in the Garage.
- Structural analysis and design for adding new opening in the wall for the room extension, added foundation, and new door lintel.
- Coatings for the floor, walls and new ceiling will be determined during the design process.

7.2 Replacement of Office Wall Mounted Thermostat.

- Further discussions with GLWA is needed to determine if a new wall mounted thermostat with the temperature display shall have limits on controls of setpoint adjustments and scheduling adjustments.

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Dan Martel, METCO
Pulanith Egodaheewa, METCO*

Date: June 1, 2023

*Subject: TM-9 Leib NFPA 820 Analysis
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) has been developed to analyze the Leib CSO Screening and Disinfection Facility (SDF) and how the current layout meets the National Fire Protection Association (NFPA) 820 requirements for classifying areas. Based on the Design Team's evaluations discussed in this TM, the Design Team is recommending the following for the two NFPA 820 connectivity issues.

- For the East and West Vestibules, the most cost-effective solution that meets the requirements of the issue is to remove the exterior vestibule walls and egress door for each vestibule, and replace with a new security gate with and exterior overhead canopy.
- For the Odor Control Duct, the preferred solution is to abandon the odor control duct between the Screening and Disinfection area and the Odor Control Room, (Garage) and fill, seal, and cut below the Garage's floor slab, with a new slab placed.

1.0 Introduction and Purpose

The Great Lakes Water Authority (GLWA) Combined Sewer Overflow (CSO) Facilities Improvements Project – Contract No. 2101475 requires the Design Team as part of the design process, to review NFPA 820 Hazardous classification for the Leib CSO SDF and analyze whether there are any issues with the facilities classifications for specific spaces.

Additionally, the Design Team's scope includes analyzing a hazardous classification connectivity issue with both of the east and west entrance vestibules, as part of the Leib HVAC-1 Task, and also reported in the reference CS-299 Report. This technical memorandum will also analyze the connectivity issues, propose alternate solutions, and evaluate the alternatives for inclusion in the project's design modifications.

2.0 Leib Screening and Disinfection Facility NFPA 820 Classifications

Table 2.1 lists of all areas in the Leib CSO SDF and the classification of each area as designed under the original PC-732 Contract that constructed the facility. These classifications will be analyzed under Section 3.0 of this memorandum. Refer to **Figure 2-1** for a floorplan of the main level of the facility showing the hazardous classifications as designed under PC-732. The below grade areas (plan not shown) are all considered Class I, Division I, Group D classification.

Table 2-1 Leib Screening and Disinfection Facility – NFPA 820 Classification Table

Area	NFPA 820 Classification as designed under PC-732
Main Level Areas	
Chemical Room	Unclassified
Maintenance Area	Unclassified
Generator Room	Unclassified
Supply Fan Room	Class 1, Division 2, Group D
Plenum	Class 1, Division 2, Group D
Electrical Equipment Room	Unclassified
Office	Unclassified
Toilet and Jan Room	Unclassified
Sampler Room	Unclassified
Odor Control Room (Garage)	Unclassified
HVAC Equipment Room	Unclassified
Corridor	Unclassified
West Vestibule	Unclassified
Stair 1	Class 1, Division 1, Group D
East Vestibule	Unclassified
Stair 2	Class 1, Division 1, Group D
Exhaust Shaft 1	Class 1, Division 1, Group D
Exhaust Shaft 2	Class 1, Division 1, Group D
Below Grade Areas	
Influent Diversion Chamber	Class 1, Division 1, Group D
Influent Channel	Class 1, Division 1, Group D
Screening Area (upper level)	Class 1, Division 1, Group D
Screening Chamber (lower level)	Class 1, Division 1, Group D
Mixing Chamber	Class 1, Division 1, Group D
Disinfection Chamber	Class 1, Division 1, Group D
Effluent Channel	Class 1, Division 1, Group D
Effluent Diversion Chamber	Class 1, Division 1, Group D
Control Gate Chamber	Class 1, Division 1, Group D

Note: Classifications assumed based on designed layout and elements as shown on the PC-732 As-built documents.

Figure 2-1
Leib CSO SDF – NFPA Hazardous Classifications Main Level Plan – as Designed Under PC-732

3.0 Analysis of Leib Screening and Disinfection Facility NFPA 820 Classifications

The Leib CSO SDF areas can be separated into two categories. Areas that fall under the NFPA 820 classification for sanitary and storm sewer liquid collection systems and treatment processes and the areas connected to them are classified as having explosion hazards, and are required to adhere to design standards that meet NFPA 820 Class 1, Division 1 or 2 (see **Table 2-1**), Group D.

3.1 Description of PC-732 Designed NFPA-820 Area Classifications

For the Leib facility, all areas below grade which serve the sewer collection and treatment systems are classified NFPA 820 Class 1, Division 1, Group D. This classification also applies to connect areas that include the stairwells that lead to and the exhaust shafts that serve the below grade areas. The Supply Fan Room and Plenum that supply fresh air to the below grade classified areas are classified by NFPA 820 as Class 1, Division 2, Group D. Design standards for this classification included explosion proof and rated electrical fixtures, equipment, and installation methods, as well certain ventilation and physical separation requirements.

Areas in the facility that are located on the main level and considered interior spaces that are not connected to the below grade areas that have the hazardous classification are considered Unclassified by NFPA 820.

3.2 Identified Connectivity Issues

Through the Design Team's analysis of the Leib CSO SDF, as constructed, the Design Team has identified two connectivity issues that require further evaluation and modifications to adhere to the NFPA requirements and provide a safe working environment. One connectivity issue, identified in the CS-299 Report and noted under the Leib HVAC-1 Task is typical for both the West and East Vestibules that are connected to the stairwells leading to the below grade sewer collection and treatment areas. The other connectivity issue identified during the analysis was the existing odor control duct installed for future use that is connected to the Garage. Both of these connectivity issues are described in further detail in the following sections.

3.2.1 East and West Vestibule Connectivity Issue

The GLWA CSO Facilities Improvements Project – Contract No. 2101475 - Leib HVAC-1 Task requires the Design Team to review the issues related to the Leib facility's existing HVAC system as identified in the CS-299 Report. One of the issues identified was the as-built configuration of the two vestibules on either side (east and west) of the building. The original design of the building as depicted in the Record Drawings show the small exterior courtyards without a roof. The current as-built condition has each courtyard with its own sloped roof de-attached from the building's main roofing system, and the opening above the courtyard wall and roof is covered with an insect screen. This current configuration of the courtyards with less than 50% free area results in these spaces being defined as interior spaces. The courtyards, now defined as interior spaces, are referred to in this memorandum as the East and West Vestibules. With each of the stairwells connected to the vestibules without physical separation to the Screening and Disinfection process area (Influent Channel, Screening, and Disinfecting Area,) the stairwells and interior spaces they are connected to share the same NFPA 820 Classification. (See **Figure 3-1** Leib CSO SDF West Vestibule and East Vestibule Enlarged Plans – Existing Conditions below).

Figure 3-1
Leib CSO SDF – West and East Vestibules Enlarged Floorplans – Existing Conditions

The HVAC system for the Screening and Disinfection area is not run continuously (24/7) based on discussions with GLWA staff (on when staff is present, off when not staffed). Per NFPA 820-2020, Table 5.2.2, Row 2.a, the screening portion of the room is Class 1I, Division I with no ventilation or less than 12 air changes per hour (ACH). The influent channel is classified as Class 1, Division 1 also per NFPA 820, Table 4.2.2, Row 14.a with no ventilation or less than 12 ACH. When 12 ACH are introduced into the space, the area is classified as Class I, Division II per NFPA 820 Table 5.2.2, Row 2.b and Table 4.2.2, Row 14.b. Since the ventilation does not run continuously, the worst-case classification applies which is Class 1, Division 1 in the Screening and Disinfection area which will also classify other areas of the building depending on the connectivity of the Screening and Disinfection area to the other areas. It should be noted that current 10 State Recommended Standards for Wastewater Facilities – 2014 recommends 12 ACH for ventilating wet wells when continuous ventilation is used, and 30 ACH for intermittent ventilation,

The vestibules are connected to the main interior space of the facility, thus also making this space the same hazardous classification. Additionally, the West Vestibule is connected to the Generator Room with an intake louver, also making the Generator Room a classified space. As currently configured/connected, the building has areas that are classified with equipment that is not designed for those classifications. See **Figure 3-2** showing the floorplan of the main level of the facility with hazardous classifications shown that represents the Design Team's analysis and

interpretation of the as-built condition and the Classifications of these spaces. The below grade areas (plan not shown) are all considered Class I, Division I, Group D classification.

Figure 3-2
Leib CSO SDF – NFPA Hazardous Classifications Main Level Plan – as interpreted by the Design Team

3.2.2 Odor Control Duct for Future Use

During the Design Team’s facility walkthroughs of Leib the Design Team discovered that an existing 48-inch diameter concrete pipe was installed between the Garage and the Screening and Disinfection area as an odor control exhaust duct to be used for a future odor control system.

The duct creates a connection point between the Screening and Disinfection area, which is classified Class I Division I per NFPA 820, Tables 5.2.2, Row 2.a and Table 4.2.2, Row 14.a with no ventilation or less than 12 air changes per hour (ACH), as described in Section 3.1.1, and the Garage which was designed to be Unclassified. However, the end of the duct is only covered with a removable metal plate (see portion of **Figure 3-3** PC-732 D-98-10-125 HVAC Diagram and **Figure 3-4**).

NFPA 820 requires that for an area to remain unclassified when adjacent to a classified hazardous area, the areas shall be physically separated. NFPA 820 defines physical separated as “A gastight partition between two adjacent spaces, or two nonadjacent spaces, with no means of gas communication between the spaces and where personnel entry into the spaces is by individual, exterior access ports with no physical connection, or an airlock.” In the Design Team’s engineered opinion the metal cap, strapped down, does not provide the gastight separation needed to de-rate

the Garage and all connected spaces in the Leib CSO SDF, particularly due to the maintenance requirements for the duct. GLWA Staff has informed the Design Team that maintenance on the unused odor control duct includes removal of the sealed metal cap on the duct or pump out infiltration water in the below grade pipe, and intermittent manned inspection of the duct. When the physical separation (metal cap) is removed, the Garage and the entire main level that is connected to the space, even if there is a man door separation, will match the same classification as the Class 1, Division 1, Group D, hazardous classification areas below grade, as defined by NFPA - 820.

Additionally, If an odor control unit were to be installed on top of this concrete duct, the NFPA classification would need to be considered. With no ventilation or less than 6 ACH, the entire room the odor control equipment is in would be classified as Class 1, Division 2 as per NFPA 820, Table 4.2.2, Row 18.a. This would classify the whole first floor as Class 1, Division 2. Nothing on the first floor is rated for this area classification at this time. Per NFPA 820, Table 4.2.2, Row 18.b and c, 6 ACH would need to be constantly running to make the area within 3 ft of leakage sources such as fans, dampers, flexible connections, flanges, pressurized unwelded ductwork, and odor-control vessels Class 1, Division 2 and the areas beyond the 3 ft unclassified. There would still be a possibility of hazardous gases getting to the other portions of the building. However, this does meet the NFPA 820 requirements.

Figure 3-3

Leib CSO SDF – Existing Odor Control Duct (Not Used, for Future Use)

Figure 3-4
Leib CSO SDF – Existing Odor Control Duct penetrating the Odor Control Room (Garage) floor (not used)

4.0 Description of Alternatives

Alternatives that address the two connectivity issues at the two vestibules and the odor control duct connection are noted in this section.

4.1 East and West Vestibule Connectivity Issue Alternatives

As part of the scope of the Leib HVAC-1 Task, the Design Team is to resolve the connectivity issues identified in the CS-299 Report by designing modifications to the building such that an Operator is still protected from the weather when traveling from the unclassified portions of the building to the classified portions of the building, while meeting current NFPA 820 code requirements. As the CS-299 Report has noted, the original design for the vestibules was to provide an open to above courtyards, enclosed only by the surrounding walls. However, the constructed facility includes canopy shed roofs over the courtyards, with any openings between the walls and roof structure covered with insect screens. This technically results in the courtyards becoming interior spaces, now defined as vestibules, and creating the connectivity issue described above. The Design Team has developed two alternatives described in this section that include modifications that provide protection from weather, and eliminate the connectivity issue. The two alternatives are typical for both the East and West Vestibules. The West Vestibule was used in both alternatives to define the proposed modifications, due to the additional restriction of an air intake louver for the Generator Room being located in the vestibule.

4.1.1 Vestibule Connectivity Issue Alternative 1 - Relocate Stairwell Entrances, Add Partially Enclosed Exterior Connecting Vestibule:

Relocate the stairwell/vestibule shared wall to allow for the relocation of the door entrance to the stairwells from the vestibule to the exterior of the building to provide NFPA 820 required physical separation, relocate the vestibule exterior door to allow for the wall to be relocated. With the stairwell entrance moved out of the enclosed (as defined by the international Building Code (IBC)) vestibule, to protect GLWA staff from weather and provide a desired level of security, an exterior partially unenclosed (openings exceed 50% of wall area as defined by the IBC) vestibule with fence panels over the openings, and an egress gate/door constructed of the fence panel material will allow staff to access the stairwells safely, securely, and protected from weather elements, while eliminating the NFPA 820 connectivity issue for the vestibules. See **Figure 4-1** for a sketched plan, and **Figures 4-2** and **4-3** for sketched elevations showing the modifications and added vestibule. Note that the new added vestibule egress at the sidewalk at the top of the ADA ramp (West Vestibule only). This alternative, applies to both the East and West Vestibules.

Alternative 1 requires the following alterations:

- Temporary shoring of the existing stairwell roof/ceiling
- Demo of existing stairwell north wall with door, frame, electrical and controls.
- Placing new concrete footing for new wall location.
- Shifting the north wall of the stair well to allow for enough clearance on the stairs top landing for a door exit directly to the exterior.
- Adding a new stairwell exit door and frame.
- Modifying the masonry entrance wall at the existing Vestibule entrance to relocate the door opening, and add a new Vestibule door and frame.
- Extending the roof over the relocated wall.
- New Exterior Unenclosed Vestibule:
 - Sawcut and removal of sidewalk as required.
 - Placing new foundation for new masonry west wall.
 - Adding new shed roof structure with standing seam metal roof to match existing, with new gutter and downspout.
 - Adding new fence panels.
 - Adding a new egress gate/door made with fence fabric.

- Adding new lighting inside new exterior unenclosed vestibule.
- Adding new lighting at exterior of egress door/gate.
- Adding card reader at exterior of egress door /gate.
- Adding bollards in the parking lot to protect new vestibule.

Figure 4-1

Leib – West Vestibule courtyard proposed modifications – Alternative 1: shifting stairwell wall, and adding new stairwell exterior door, adding new exterior unenclosed vestibule.

Figure 4-2
Leib – West Vestibule courtyard proposed modifications – Alternative 1: West Elevation

Figure 4-3
Leib – West Vestibule courtyard proposed modifications – Alternative 1: North Elevation

Figure 4-4
Leib – Conceptual Site Plan with Vestibule Extensions shown

4.1.2 Vestibule Connectivity Issue Alternative 2 - Remove Courtyard Wall and Entrance Door Entrances:

Remove the vestibule exterior wall and entrance door and provide a security gate in its place to provide enough free area of opening for the vestibule to be considered an exterior space. Per NFPA 820, Annex A, Figure a.4.2(b) (See **Figure 4-5**), a three-ft envelope around a door to a wet well or basin serving separate or combined sanitary sewer shall be considered Class 1, Division 2, when the Screening and Disinfection area has ventilation under 12 ACH. Per the Design Team’s discussions with the facility staff, when staff is present at the building the ventilation in the Screening and Disinfection area is on, and when the site is unstaffed, the ventilation to the Screening and Disinfection area is turned off, creating the Class 1, Division 2 envelope at the door. The envelope, however, does not encroach on the building’s door area or the Generator Room’s intake louver.

During the February 10, 2023 workshop, the discussion of needing a panic bar to the security gate was discussed. After further review and evaluation, the new security gate that will provide egress from the building will not require a panic bar. The security gate will be required to have a “passage” type lock that is always unlocked from the inside, and will only lock from the outside, similar to the existing lockset on the existing egress doors at the facility (see **Figure 4.6** for an image of the typical egress door and hardware at the existing vestibules). The passage lock will be electrified and connected to the security system’s credential reader, to allow secured access. A panic bar is only

required when the Michigan Building Code (MBC) or the NFPA Life Safety Code has determined that the space a person is egressing from is a Use Group H - High-Hazard, or Use Group A-Assembly and Use Group E - Educational when the occupant load exceeds 50 people. For the Leib CSO SDF, the MBC Use Group is F-2: Factory Low-Hazard, where there is a low risk of a fire hazard.

This alternative can apply to both the East and West Vestibules.

Figure 4-5
Wet Well or Basin Serving Separate or Combined Sanitary Sewer from NFPA-820; Illustration of Table 4.2.2
Rows 14 and 32

Figure 4-6
Existing egress doors at the West Vestibule and West Stairwell with Passage type lockset (typical for the East Vestibule and Stairwell).

Alternative 2 requires the following alterations:

- Removal of the exterior wall at the entrance courtyards and entrance doors.
- Removal of exterior light fixture at the entrance door, add additional new lighting.
- Removal of insect screening above wall to be removed, and replace with a bird screen or screen that allows the free open area of the combined gate and screen to exceed 50% of the area. An insect screen may not allow for this required percentage.
- Rework wall coping.
- Adding security gate with egress hardware.
- Adding exterior Canopy for additional weather protection at the gate.
- Adding credential reader at new location.

See **Figure 4-7** marked drawing with proposed reconfiguration. **Figure 4-8** shows the current open area provided above the exterior partial wall with the entrance door below, currently covered with a bug screen. This open area above will contribute to the required 50% open area needed at the exterior wall. Both the West and the East Vestibules share this condition.

Figure 4-7
Leib CSO SDF – West Vestibule courtyard proposed modifications – Alternative 2: Removal of Vestibule Exterior Wall and Door, and Install a Security Gate with Egress Hardware.

Figure 4-8
Leib CSO SDF – Showing Open Area above West Vestibule partial wall, currently with a bug screen. Similar to the condition at the East Vestibule.

4.2 Odor Control Duct for Future Use Connectivity Issue Alternatives

As described in Section 3.1.2, during the Design Team's facility walkthroughs of Leib and NFPA 820 analysis the Design Team discovered that the existing 48-inch diameter concrete pipe installed between the Garage and the Screening and Disinfection area as an odor control exhaust duct to be used for a future odor control system creates a connectivity issues point between the hazardous classified spaces below grade and the intended to be Unclassified spaces on the main level. The Design Team has developed two alternatives to address the connectivity issue.

4.2.1 Odor Control Duct for Future Use Connectivity Alternative 1 - Abandon Duct, Fill, Seal:

The provisions constructed for a future odor control system at the Leib CSO SDF have never been utilized. The Design Team has confirmed with GLWA that the odor control duct can be abandoned, provided that the concrete pipe/duct is filled with a material that could be removed in the future, if

GLWA or permitting agencies require use of it. Discussions with the facility staff indicate that the concrete pipe duct experiences ground water infiltration and occasionally needs to be dewatered and inspected. The location of the duct penetration through the floor of the Garage limits the flexibility for uses for this room, which includes an overhead door for deliveries, and is used as a storage space. The concrete pipe duct can be abandoned, cut below the existing slab, filled, and the floor opening replaced with a new slab to open the area in the room for other uses. Per the Design Team's discussion during the February 10, 2023 workshop with GLWA, prior to abandoning the duct, the associated ductwork in the Screening and Disinfection area shall be disconnected and can be partially left in place for future use or removed. The wall opening in the Screening and Disinfection area where the odor control pipe/duct penetrates shall be filled with concrete that is doweled into existing wall with two rows of water stop to prevent future leakage. Also, prior to abandoning the pipe/duct, it shall be inspected for observed infiltration, repaired accordingly, leak tested for at least 90 days, then filled with a material that can be removed in the future should GLWA or a permitting agency require that the duct/pipe be needed for an odor control system. The pipe shall then be capped in the Garage with a concrete slab, rated for vehicle loads, doweled into the existing slab and sealed at the perimeter,

Alternative 1 requires the following alterations:

- Removal of odor control ductwork, or a portion of, in the Screening and Disinfection area.
- Inspection, repair and testing for infiltration.
- Cutting the pipe duct below the existing slab.
- Filling the Screening and Disinfection wall opening and seal.
- Filling the concrete pipe with a fill material that can be removed in the future (possibly sand or polyurethane foam).
- Placing subgrade and vapor barrier.
- Placing concrete slab, tied into existing slab.
- Repair floor coating.
- Renaming the Garage as Delivery/Storage.

4.2.2 Odor Control Duct for Future Use Connectivity Alternative 2 – Duct Remains, Seal Duct Openings in Screening and Disinfection Area:

Should GLWA elect to keep the existing concrete pipe duct for a future odor control system, the odor control duct in the Screening and Disinfection area has grilles that expose the ductwork to the classified environment. The grilles can be removed and replaced with duct opening caps with

gasketed seals and the ductwork can be inspected, sealed and pressure tested to verify a gastight physical separation to meet the requirements of a NFPA 820. Sealing the ductwork in the classified area will allow the sealed cap to be removed for maintaining the duct making the Garage and all other spaces connected to it a NFPA 820 Class I, Division I, Group D classified space.

Alternative 2 requires the following alterations:

- Remove the existing grilles on the odor control duct located in the Screening and Disinfection area.
- Replace grilles with blanks that are sealed to prevent gasses from entering the duct.
- Confirm any other penetrations in the ductwork or at the thru-wall duct penetration in the Screening and Disinfection area is sufficiently sealed.
- Perform a pressure test on the ductwork to confirm the gastight physical separation.

4.3 Evaluation Criteria and GLWA Input when discussing alternatives.

4.3.1 Evaluation Criteria:

Alternatives for the vestibule connectivity issue discussed in Section 4.1 will be analyzed in the subsequent section using the following criteria.

- Protection from Weather
- Security
- Costs

Alternatives for the odor control duct for future use connectivity issue discussed in Section 4.2 will be analyzed in the subsequent section using the following criteria.

- GLWA future considerations
- Costs

5.0 Alternatives Analysis and Evaluation

To analyze the alternatives noted above for the two NFPA 820 connectivity issues, each alternative is analyzed for advantages and disadvantages listed, and evaluated with based on the listed evaluation criteria for each issue.

5.1 East and West Vestibule Connectivity Issue Alternatives

This section discusses the two alternatives to be analyzed and evaluated for the East and West Vestibule connectivity issues.

5.1.1 Vestibule Connectivity Issue Alternative 1 - Relocate Stairwell Entrances, Add Partially Enclosed Exterior Connecting Vestibule: – Advantages and Disadvantages:

Advantages:

- Eliminates connection from the Screening and Disinfection area and Stairway to the remainder of the building, allowing the building main level hazardous classification to be Unclassified.
- Provides covered and partially enclosed connectivity between the Main Level and the Stairwells leading to the Screening and Disinfection level.
- Compared to Alternative 2, allows the entrance courtyards to remain covered with a bug screen, providing protection Employees.
- Maintains or improves the level of security.

Disadvantages:

- Relocating bearing walls and adding new support beam
- Relocating exterior courtyard door which will require adjustments to multi-wythe wall.
- Will need to extend roof above the stairwell.
- Encroachment on existing sidewalk.

5.1.2 Vestibule Connectivity Issue Alternative 2 - Remove Courtyard Wall and Entrance Door Entrances: – Advantages and Disadvantages:

Advantages:

- Reclassifies the courtyard as an exterior space, thus eliminating the classified connection between the Screening and Disinfection Area Stairwell and the main level of the building.
- Less modifications to the building as compared to Alternative 1.

Disadvantages:

- The Entrance Courtyard is unprotected from bugs and wind or driving rain. A roof overhead still exists.

5.1.2 Vestibule Connectivity Issue Alternative Evaluation:

Table 5-1 Vestibule Connectivity Issue Alternative Evaluation:

Alternative	Protection from Weather 1-5	Security: 1-5	Costs: 1-5	Total Score: 1- 15
Alternative 1 - Relocate Stairwell Entrance, Add Exterior Canopy.	3	4	1	8
Alternative 2 – Replace Courtyard Wall and Entrance Door Entrances with a Security Gate, Add Exterior Canopy.	3	4	5	12

The numbers shown in **Table 5-1** are based on the Design Team’s evaluation of the criteria identified in Section 5.1.2, 1 being the lowest score and 5 being the highest based on comparison of both alternatives. The total score is an accumulation of the scores shown.

Based upon the above alternative evaluation, and previous discussions with GLWA during the February 10, 2023 workshop, Alternative 2 that includes removal of the exterior vestibule wall and egress door, and replacing with a new security gate with an exterior overhead canopy is the preferred alternative.

5.2 Odor Control Duct for Future Use Connectivity Issue Alternatives

This section discusses the two alternatives to be analyzed and evaluated for the odor control duct for future use connectivity issue.

5.2.1 Odor Control Duct for Future Use Connectivity Alternative 1 - Abandon Duct, Fill, Seal Advantages and Disadvantages:

Advantages:

- Creates a NFPA 820 required gastight physical separation between the Screening and Disinfection area and Garage.
- Eliminates the water infiltration inside the pipe duct issue and associated maintenance and inspection.
- Provides more usable space in the Garage.

Disadvantages:

- Analysis is needed to confirm subgrade can support additional weight of filled duct.

5.2.2 Odor Control Duct for Future Use Connectivity Alternative 2 – Duct Remains, Seal Duct Openings in the Screening and Disinfection Area – Advantages and Disadvantages:

Advantages:

- Creates a NFPA 820 required gastight physical separation between the Screening and Disinfection area and Garage.
- Allows for the future installation of an odor control system with the ventilation requirement summarized above to avoid hazardous classification for the entire floor.
- Lower cost than Alternative 1

Disadvantages:

- Requires maintenance to inspect and dewater the concrete pipe duct.
- Pipe remains an obstacle in the middle of the room.
- A future odor control system will require additional modifications to the existing building's HVAC system and odor control ductwork to come in compliance with NFPA 820.
- Existing ductwork work needs to be inspected, sealed and pressure tested.

5.2.3 Odor Control Duct for Future Use Connectivity Issue Alternative Evaluation:

Table 5-2 Odor Control Duct for Future Use Connectivity Issue Alternative Evaluation:

Alternative	GLWA Future Considerations 1-5	Costs: 1-5	Future Storage/Maintenance: 1-5	Total Score: 1-15
Alternative 1 - Abandon Duct, Fill, Seal	1	2	5	8
Alternative 2 – Duct Remains, Seal Duct Openings in Screening and Disinfection Area	3	3	1	7

The numbers shown above are based on the Design Team's evaluation of the criteria identified in Section 5.1.2, 1 being the lowest score and 5 being the highest/best based on comparison of both alternatives. The total score is an accumulation of the scores shown.

Based upon the alternative evaluation, Alternative 1 has the higher score. Considering the above alternative evaluation and previous discussions with GLWA during the February 10, 2023 workshop, GLWA would like the Design Team to pursue Alternative 1 that provides more flexibility in the area used for storage and eliminates the maintenance component for the duct work.

6.0 Summary and Recommendations

Section 7.0 provides a summary and recommendations for the two NFPA 820 connectivity issues identified and discussed in the description, evaluation, analysis above.

6.1 East and West Vestibule Connectivity Issue Alternatives

After discussions with GLWA, the primary criteria when evaluating the alternatives include resolving the NFPA 820 connectivity issue, and providing connectivity from the main level to the Screening and Disinfection level below that is protected from weather and is secured. While both alternatives technically resolved the NFPA-820 connectivity issue, Alternative 2 provides the weather protection and security desired by GLWA. The Design Team recommends that for both the East and West Vestibule, that the least costly solution that meets GLWA's requirements for security and weather protection is removal of the exterior vestibule wall and egress door, and replacing with a new security gate with an exterior overhead canopy.

6.2 Odor Control Duct for Future Use Connectivity Issue

With the Leib CSO SDF operating over 20 years without any significant odor issues requiring an odor control system be installed, the GLWA and the facility will benefit by abandoning, filling, and sealing the existing unused below grade odor control duct. As described in Sections 4.2 and 5.2, the current physical separation method does not meet the NFPA 820 requirements. The Design Team recommends that GLWA take immediate steps to temporarily seal the duct in a manner that provides a gastight separation between the duct and the Garage, with no means of gas communication between them. This will bring the current connection through the odor control duct into compliance with NFPA 820.

As part of the GLWA CSO Facilities Improvements Project – Contract No. 2101475 work, The Design Team is recommending the abandonment of the odor control duct between the Screening and Disinfection area and the Garage. The duct would be filled, sealed, and cut below the Garage's floor slab, with a new slab placed. This allows for more flexibility in the space, currently being used for storage and deliveries. The additional benefit to GLWA is the maintenance and difficult inspection of the duct is eliminated from the facilities maintenance requirements.

6.3 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

6.3.1 East and West Vestibule Connectivity Issue:

- Per the discussions that took place at the TM Workshop and with the CSO Manager, Alternative 2 was selected as the best solution, that provides adequate security and the desired weather protection.
- A bird screen is acceptable for the desired protection. A bug screen is not needed per discussions with the CSO Manager.

6.3.2 Odor Control Duct for Future Use Connectivity Issue:

- Per the discussions that took place at the TM and Preliminary Review Workshops, the Odor Control Duct shall be abandoned as noted above in this Technical Memorandum.

7.0 Next Steps

The following list of items will require advancement/further development as the design process advances for the two recommended paths summarized in Section 7.0 for resolving the NFPA 820 connectivity issues for the East and West Vestibules and the odor control duct for future use noted above.

7.1 East and West Vestibule Connectivity

- Further detailed review and design to evaluate different types of screens to be used with the security gate so that the complete gate and screen assembly allows for the required 50% free area.
- Coatings for the floor, walls and new ceiling will be determined during the design process.

7.2 Odor Control Duct for Future Use Connectivity

- Structural analysis needed to confirm subgrade can support additional weight of filled duct.
- Review material options for filling the duct that allows for removal in the future and can support the transferred loads from the new slab added above.

2.3 Structural, TM-3 and Embedded in Various TM's

Oakwood RTB, TM-3 and embedded in various TM's

- Screen Facility, core drills of floor slab for conveyor drains
- Storm PS, removal of cast in place concrete covers over sanitary flow trench
- Sanitary PS influent channel, removal of top of stairs and replace with concrete sloped slab
- Concrete equipment pads for new chemical recirculation pumps
- Openings and hatches for sample pumps in CSO basins

Leib SDF, and embedded in various TM's

- Modifications to concrete
 - Stepped bottom slab in screen inlet channels to be sloped
 - Screen channel walls at each existing Romag screen to be lowered 1-ft
 - Screen channel walls at COPA screen channels modified to accommodate new Romag screens
 - Remove conc duct above garage floor
- Modifications associated with Architectural improvements at entrances and supply fan
- Fill below grade duct with sand
- Provide water proofing on the inside of the concrete duct
- Provide reinforced concrete wall or slab at each end of duct to isolate from room
- Removal and reinstallation of chemical facility wall to accommodate tank replacement
- Concrete equipment pedestals for new chemical recirculation pumps
- Exterior wall modifications to accommodate SF-1 improved access

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

From: Steve Fehniger, CDM Smith

Date: June 1, 2023

*Subject: TM-3 Sanitary PS Concrete Stair Modification Evaluation (OKW-PUMP-2)
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) summarizes the evaluation conducted to address the condition in which the wastewater is aerated as it flows down the concrete stairs entering the sanitary pump station wet well (east and west) to minimize or eliminate air entrainment/odor release.

Recommendation: the recommended modification to minimize the aeration of the wastewater and minimize associated maintenance is to replace the stair with a sloped concrete fillet.

Two alternatives were included in the evaluation:

- The first removes the concrete stair immediately upstream of the bar screen and replaces it with a sloped fillet (sloping from the storm wet well bottom slab [approximately 50.3'] to the influent channel at the base of the stair [41.0']) to minimize cascade affect and aeration if the sanitary flow trench is blocked and flow is conveyed over the stair as approach the sanitary influent channel.
- The second uses an inlet chute connected to a discharge pipe to funnel flow conveyed toward the stair into a closed conduit discharging at the base of the stair. The configuration of the inlet chute and pipe would be developed to contain the majority of the flow conveyed over the stair.

Alternatives evaluation criteria were grounded in the guiding principles for the project with an emphasis on ability to meet the goal to minimize or eliminate air entrainment/odor release coupled with enhanced reliability, maintenance reduction and simplicity.

1.0 Introduction and Purpose

TM-3 is focused on evaluation of the sanitary pump station (east and west) concrete stairs to minimize or eliminate the condition in which the wastewater is aerated as it flows down the concrete stairs entering the wet well.

This TM will not answer questions related to the obstruction of flow through the sanitary flow trench located beside the top of concrete stair.

2.0 Existing System(s) Description (and/or Conditions)

The sanitary wet wells are each configured with three flights of stairs cast into the concrete floor slab or fillets (45-degree sloped concrete in corners and between pumps) as shown in **Figure 2-1**.

Figure 2-1
East Sanitary Wet Well Plan with Concrete Stairs Identified (west wet well similar)

The stairs can be identified by location:

- Stair A: downstream of underflow baffle wall
- Stair B: beside watertight door
- Stair C: sanitary influent channel upstream of screen

As clarified at TM workshop No. 1 held on April 5, 2023, the aeration of the wastewater has occurred only at stair C. It appears that this has been caused by debris accumulation in the sanitary flow trench to the extent that flow through the trench was fully or partially obstructed resulting in flow being conveyed over the storm wet well floor to the top of Stair C rather than discharged to the sloped concrete surface at termination of the trench adjoining the stair. This has resulted in aerating the wastewater at times. The same condition can exist in the approach to both wet wells.

For reference, the intended approach flow for this wet well type is represented in **Figures 2-2 and 2-3**.

Figure 2-2
East Sanitary Wet Well – Intended Flow Path to Provide Optimal Approach Flow Conditions

Figure 2-3
East Sanitary Wet Well Section – Intended Flow Path to Provide Optimal Approach Flow Conditions

From discussion with the Great Lakes Water Authority (GLWA) the Design Team also understands that the stairs have not been utilized historically when staff have been working in the wet well since the stairs remain slippery even after cleaning.

3.0 System Evaluation

The evaluation of the concrete stair has focused initially on determination of which stair (A, B or C) has wastewater flowing down it leading to aeration. This evaluation has determined that only stair C has been of concern for this operating condition as described in Section 2.

The second portion of the evaluation was focused on how to prevent the aeration from occurring in the future. The path forward for evaluation was based on addressing the flow down the stair and two alternatives are discussed in Section 4.

The evaluation also considered if there would be value to remove stair A or B as part of the proposed modifications.

Stair A provides a means of transitioning from the significant elevation change from the channel upstream of the vertical underflow baffle and the bottom of the sanitary wet well. This stair is not causing aeration of the wastewater. Therefore, the stair is not recommended for modification as part of this project.

Stair B is not typically utilized by operations or maintenance staff for wet well entry due the slippery condition of the stairs, even after cleaning. However, if the watertight door is utilized this stair would be an improvement over traversing a 45-degree fillet which would replace this stair to match the sidewall fillet slope. Therefore, since stair B is not causing aeration of the wastewater and provides a more accessible means to the watertight door than a 45 degree slope the stair is not recommended for modification as part of this project.

4.0 Description of Alternatives

There were two alternatives considered to address the aeration of wastewater as cascades down stair C which are described in this section.

4.1 Remove concrete stair C and replace with concrete fillet

This alternative (Alternate 1) removes the concrete stair immediately upstream of the bar screen and replaces it with a sloped fillet. The fillet would slope from the storm wet well bottom slab (approximately 50.3') to the influent channel at the base of the stair (41.0') to minimize cascade affect and aeration if the sanitary flow trench is blocked and flow is conveyed over the stair as approach the sanitary influent channel.

4.2 Add piping to bypass the concrete stair C

This alternative (Alternate 2) uses an inlet chute and pipe to funnel flow conveyed toward the stairs into a closed conduit discharging at the base of the stair. It is assumed that the configuration of the inlet chute and pipe would contain a portion of the flow conveyed toward the top of stair. It would be a challenge to capture all the flow.

The alternative includes an initial concern for the potential to passively bypassing the pipe (if spill over inlet chute) resulting in continued aeration. In addition, the design team is concerned that

debris may catch on the chute inlet or within the pipe leading to an additional maintenance requirement at a difficult to access location.

4.3 Alternatives Evaluation Criteria

The alternatives evaluation criteria are grounded in the guiding principles for the project with an emphasis on ability to meet the goal to minimize or eliminate air entrainment/odor release coupled with enhanced reliability, maintenance reduction and simplicity.

5.0 Alternatives Analysis

Alternate 1, which replaces the stair with concrete fillet, is superior on a technical basis to the chute/pipe alternative for all evaluation criteria. Therefore, recommend the concrete fillet based on evaluation of non-cost factors given the importance to align with guiding principles (minimize maintenance, enhanced reliability, simple) with an alternative which will address the concern to the maximum extent feasible.

5.1 Conceptual Structural Modifications to Accommodate Alternate 1

From structural perspective, the existing stairs can be modified by jackhammer or saw cutting to remove the steps including the embedded rebars down to the surface to accommodate the new sloped concrete surface described above. The contractor will then remove and scarify to two inches below the exposed sloping surface. Once the contractor has prepped the surface new concrete repair mortar will be applied in approximately a two-inch thick layer. At the bottom of the existing stair a groove will be chipped out to avoid a feather edge at the low point of the fillet. The repair mortar will be troweled smooth to match the adjacent surface. **Figure 5-1** generally illustrates this approach.

Figure 5-1
Conceptual Structural Modifications to Stair C

6.0 Summary, Recommendations and Key Decisions

The evaluation concluded that the only concrete stair which requires modification as part of this project is Stair C as shown in **Figure 6-1**. The recommended modification to minimize the aeration of the wastewater and minimize maintenance is to replace the stair with a concrete fillet with a slope to transition from storm wet well bottom slab to the sanitary influent channel bottom slab.

Figure 6-1
East Sanitary Wet Well – Recommended Concrete Stair Modification (west wet well similar)

6.1 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

- Stair C modification to remove concrete steps and replace with sloped concrete fillet/ramp as conceptually shown in Section 5.
- No modifications required to Stair A or Stair B.

7.0 Next Steps

Not Used.

2.4 Security, TM-24

Leib SDF

- Add camera for new entrance to site
- Key card/intercom panel for badge access at new entrance
- New fencing security provisions

TM-24 can be found in Section 2.1.

2.5 Process Mechanical, TM-2, TM-4, TM-5, TM-15, and TM-22

Oakwood RTB, TM-2, TM-4, TM-15, and TM-22

- Rehabilitation/modification of Storm Pumps
 - Modify (water lube bearings changed to grease lube) for each storm pump
 - *Modify support grating over opening at storm pump motor room to support grease lube system skid (one corner of opening)*
 - Small & Large Pumps, 66x54 WCA and 88x72 WCA included (total of eight)
 - Disassembly, Removal and shipping to factory
 - Factory witness test (TBD)
 - Installation, startup, training and return shipping
 - Modify existing seal/lube/cooling water system (1 dedicated per storm pump) to serve the only remaining load: motor thrust bearing cooling
- Clean both storm wet wells, both sanitary wet wells and influent tunnels - vactor or submersible slurry pump removal, fillets and splitters
- Changes to Ovation programming controlling and monitoring storm & sanitary pump systems
- Modify screenings conveyor to include three drain sections (drain boxes)
- Relocate flushing valves in CSO Basin
- Add conditioning pump and flushing water nozzle system in each CSO basin drainage sump
- Modify storm wet well flushing system in each wet well

Leib SDF, TM-5 and TM-22

- Rehabilitate existing Romag screens
- Replace all COPA screens in the two screen channels with Romag screens
- Replace the two SS hydraulic lines to each Romag screen (TBD)
- Replace screen control panels
- Add flushing water system to screen inlet channels and screenings channel

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

From: Steve Fehniger, CDM Smith

Date: June 1, 2023

*Subject: TM-2 Storm Pump Rehab and Wet Well Cleaning (GLWA OKW-PUMP-1B)
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The problem statements incorporated and addressed in this technical memorandum (TM) include how to approach wet well cleaning (short and long term), several elements of rehabilitation of the storm pumps and evaluation of a separate contract for the storm pump specific work items.

Recommendations

Cleaning: Near-term cleaning evaluation was conducted to determine the major elements of a wet well cleaning specification which will be developed in final design phase to define the requirements for cleaning the two storm and two sanitary wet wells as part of this project. For long-term cleaning, the evaluation defined the path forward to develop Standard Operating Procedures (SOP) which will incorporate the storm wet well flushing system/sanitary pump operation cleaning after each wet weather event as well as recommended intermittent cleaning procedures.

Storm pump rehabilitation:

Storm pump rehabilitation recommendations included the following:

- Pump manufacturers to list in the storm pump rehabilitation specification: Johnston/Sulzer, Xylem Flygt AC-Custom Pump and Fairbanks Nijhuis.
- Scope of rehabilitation includes replacement of the shaft sleeves, line shaft bearings and bowl bearings.
- Proceed with grease lubrication system which was determined to be technically feasible for the application.
- Grease lubrication system configuration, redundancy, location and other recommendations listed in Section 7.

- Reconfigure cooling water system for motor thrust bearing to be connected to the intermediate level process drain system and replace the sump pump to meet new conditions of service.

Storm pump as separate contract: Proceed with a separate contract for the storm pump rehabilitation/modification due to the construction phase duration being insufficient to incorporate the time required to perform the work.

The evaluations performed to determine the above recommendations were divided into the three focus areas as follows:

The evaluation for wet well cleaning focused on development of core requirements and constraints to include in the cleaning specification coupled with how much the sanitary pumps could be utilized as part of this activity. The long-term cleaning evaluation included qualitative benefit assessment to modify wet well access capabilities relative to clearances available for cleaning equipment. In addition, a list of items to include in SOP which summarizes the future cleaning activities utilizing the storm wet well flushing system and intermittent wet well entry.

The storm pump rehabilitation evaluations were subdivided to determine which pump manufacturers could perform the required work, summarize the anticipated pump rehabilitation requirements based on findings from ST-5 2022 rehabilitation, assess feasibility to field modify ST-5 to add grease lubrication in the field, and technical feasibility of pumps to be modified to convert water lubed bearings to grease lubrication. The evaluation included a related determination of the modifications of the seal/cooling/lube water system to be coordinated with the grease lubrication system including associated disposal method for spent motor cooling water.

The evaluation of separation of the storm pump work from the remainder of the project as a stand-alone set of contract documents, to be bid before the remainder of the project, focused on feasibility to separate this work from the remainder of the project, potential cost, and schedule efficiencies.

1.0 Introduction and Purpose

TM-2 is focused on evaluation/investigation of two distinct pump system elements: storm pump rehabilitation/modification (rehab) and cleaning of the storm and sanitary wet wells contained within the Oakwood Pump Station.

The TM is structured to first cover the wet well cleaning and then storm pump rehab within each section.

The cleaning evaluation considers both the near-term (work to be performed as part of this project) and long-term (operations/procedures to be performed after this project). The storm pump rehabilitation evaluation focus is on required improvements to restore the pumps to full functionality, assess technical feasibility of line shaft and bowl bearing conversion to grease lubrication, maximize reliability while reducing maintenance to the extent feasible.

This TM will not answer all storm pumping system related questions. Refer to technical memoranda/reports developed on the topics of storm pump control philosophy revisions (TM-15), storm wet well physical model study, and storm wet well flushing system improvements (TM-22) for coverage of those topics.

2.0 Existing System(s) Description (and/or Conditions)

The existing Oakwood storm pump station is configured with a split modified trench wet well as the intake for the storm pumps. Downstream of each trench is a solids handling type wet well equipped with a total of four submersible sanitary pumps as shown in **Figure 2-1**. The wet wells are connected only at the upstream junction chamber which is located near the southern limit of the facility site.

Figure 2-1
Oakwood Storm and Sanitary Wet Well Configuration (PC-755 Record Drawing D-04-08-405)

2.1 Wet Well Debris Accumulation/Cleaning

Debris accumulation in the storm and sanitary wet wells occurs regularly. This requires periodic manual cleaning. The deposited debris is primarily composed of a heavy sediment/sand/sludge mixture. The rate of deposition varies as a function of the number of wet weather events, operation of the storm and sanitary pump stations, and the frequency of sanitary pump station screen manual cleaning. The 3-inch clear coarse bar racks tend to accumulate rags which lead to blinding over time and a resultant significant (presently 10-ft where full screen field height is installed) differential head across the screen. This condition likely limits debris transport to the sanitary pumps.

At the time of this writing, as part of a separate project, a contractor was preparing for a second attempt to clean the wet wells. In addition, at the time of the cleaning the Great Lakes Water Authority (GLWA) may decide to remove the lowest portion of the complete sanitary pump station screen to avoid the blinding and associated backup of debris accumulation in the storm wet well and sanitary flow trench based on performance with the modification of the other sanitary pump station screen completed more than a year ago.

The quantity of debris accumulation is substantial over time with a present cleaning frequency of approximately every third year as noted by operations staff. Based on observations from the storm wet well expansion zone in Fall 2022 (during first recent attempt to clean wet well), there is significant debris accumulation in the wet well. Discussions with operations staff identified that one of the single most valuable improvements to the facility would be to increase the cleaning frequency to annual.

There is an existing flushing system in each storm wet well and at the beginning of the sanitary flow trench which is utilized infrequently at best and has not demonstrated effective cleaning performance over the service life of the facility. This system is described and evaluated in TM-22 titled Flushing Systems.

2.1 Storm Pumping System

The Oakwood storm pump system is comprised of eight vertical mixed flow storm pumps positioned within the two wet wells with “small” variable speed-controlled pumps at the upstream end of each wet well followed by “large” vertical-mixed flow pumps. The pumping units were all furnished and installed as part of the original construction. The pumps were manufactured by ITT Flygt (now Xylem Flygt AC-Custom Pump) and the motors were manufactured by Hyundai Ideal (now Ideal Electric). The pump station has a firm pumping capacity of 1675 cfs (1.1 BGD) at the design total head with one of the large pumps off-line.

No major modifications have been made to the pumping units since placed into service in 2012. One pump (ST-5) was rehabilitated by Kennedy Industries in 2022. Major component replacement included line shaft and bowl bearings and shaft sleeves as described in Section 3.

Pump details are included in **Table 2-1**.

Table 2-1 Storm Pumping Units Summary

Pump Nos.	Pump Description	Design Point Total Head, ft	Design Point Flow Rate, cfs (mgd)	Motor Full Speed, rpm	Motor HP	VFD speed controlled, Y/N	Present Speed Range, % speed	Discharge Size, in.
ST-1 and 2	Small Pump	48	150 (97)	594	1500	Y	75 - 100	54
ST-3, 4, 7 and 8	Large Pump	48	275 (178)	446	2000	N	NA	72
ST-5 and 6	Large Pump	48	275 (178)	446	2000	Y	75 - 100	72

2.1.1 Present Storm Pump Station Operations

The storm pump station is normally operated manually from the Ovation workstation in the pump station control room. The station is commonly left in auto mode when facility is not staffed to facilitate system operation during wet weather event as triggered by wet well level setpoints. On average the station operates about 25 times per year. Each station operation involves at least one

storm pump running.. This operational frequency was based on review of downstream equipment systems which are required to be running before any storm pump will start (screenings conveyor data utilized) as determined through review of operational data from September 2019 – November 2022, excluding conveyor starts for post-event cleaning.

Present wet well level-based pump setpoints (Detroit datum):

- Lead pump start: 73 ft
- Lag pump start: 76 ft
- Maximum level: 78 ft
- Last pump in operation stop: 65 ft

Based on observations and discussions with operations staff as part of ride-along site visits, the selection of the first pump to start is an operator preference and can be a small pump or large pump (constant or variable frequency drive [VFD]). This decision is guided in part by desire to distribute the runtime between the storm pumps. In addition, some operators favor starting an event with a large pump as they feel the ability to dose a high concentration of sodium hypochlorite at beginning is greater with the corresponding larger metering pump than the small pumps. Most events require only one storm pump to operate at a time with fill/draw approach with a resultant varied number of pump operation cycles per event.

The speed of the VFD speed-controlled pumps is automatically controlled “behind the scenes” via Ovation programming as the operations staff do not modify the VFD speed. Operators indicated the speed ramps up when the wet well level increases. For the events observed these pumps remained at minimum speed as the flow rate did not continue to rise after the pump was turned on. This results in operation outside the Allowable Operating Region (AOR) with associated reduced service life and lower pump efficiency. However, for the ride along witnessed events the pumps were able to convey the combined sewage required to meet the needs of the application in this operating condition.

The subsequent pumps turned on is an operator decision with consideration of not starting a pump which has recently been shut down to allow the motor to cool down.

2.1.2 Present Pump Line Shaft and Bowl Bearing Lubrication System Operation

The pump line shaft and bowl bearing water lubrication system operation has been a reliability challenge due largely to debris in the combined or sanitary sewage entering the enclosing tube and plugging the bearing lubrication grooves when the level in wet well is above the impeller if the cooling/seal/lube water is not providing a clean water purge of the enclosing tube during this operating condition. The plugging has resulted in the inability to convey water out the enclosing tube. If this occurs storm pump operation is suspended until the flow path is reestablished to allow water to serve all intended functions. This plugging has also led to seizing of the pump in some

cases. Both of these conditions (plugging and seizing) have resulted in pump downtime and substantial maintenance efforts to return pumps to operational condition.

As a result, the present operation of the cooling/seal/lubrication water system is to run continuously (every day) independent of whether a storm pump is in operation or if the wet well level is above the pump bell. This operating practice has resulted in reliable operation of the storm pumps. However, the continuous use of water also creates a high associated operating cost for the secondary water supplied to these systems (potable water downstream of a backflow preventer). At present water rate, approximate water cost of \$846,000 per year at Oakwood facility which as far as the Design Team is aware is predominately utilized for this system demand as detailed in Section 3.2.10.3.

3.0 System Evaluation

The evaluation of the cleaning system/approach for the storm and sanitary wet wells summarized in the following section has been divided into two, time horizons (near-term and long-term). The evaluation of storm pump rehab is first focused on ST-5 rehab findings as relate to rehab needs of all pumps followed by feasibility evaluation for conversion of the bearing lubrication system from water to grease.

3.1 Cleaning System/Approach Evaluation

3.1.1 Cleaning System/Approach Evaluation - Near-term cleaning activities

As described in Section 2, the storm and sanitary wet wells tend to accumulate debris over time. From discussions with operations staff the Design Team learned that the flushing system for the storm wet well is infrequently utilized in part due to one of the system motorized isolation valve requiring service. However, given the depth of debris in the wet well observed in the fall it is unlikely that the flushing system would be able to clear the present quantity of debris.

Evaluation and effectiveness of the flushing system is discussed in TM-22 thus not a focus herein. In addition, the Design Team does not plan to use the flushing system in the cleaning activity performed by the contractor as part of this project.

The near-term cleaning activities are independent of the cleaning contract as part of a separate project at the time of this writing.

The focus of the near-term cleaning is to develop a cleaning specification to require the contractor to clean all sludge and debris from the two storm and two sanitary wet wells as part of construction phase activities.

The wet well cleaning specification will define the requirements including the following:

- Scope of cleaning as shown in **Figure 3-1**.
 - Both storm and both sanitary wet wells

- Installed portion of both sanitary influent channel screens
- 18-foot diameter approach tunnels and sanitary trenches up to the junction chamber (up to stop plate)

Figure 3-1
Oakwood Storm and Sanitary Wet Well Areas to be Cleaned (PC-755 Record Drawing D-04-08-405)

- Constraints
 - Access through intermediate level, if storm pump is removed, will not be allowed due to separation requirements to not interconnect hazardous and unclassified areas.
 - Limitations on use of the sanitary pumps to convey water above the debris and, if GLWA approved, fluidized debris.
 - Limited clearance around pumps, fillets, splitters and sanitary flow trench
 - No heavy machinery (weight to be defined) will be operated or moved across the sanitary trench covers (6-inch" thick reinforced concrete) provided near each pump bell.
- Allowable points of access as shown in **Figure 3-2**.
 - Hatch at top of each expansion zone (6 ft x10 ft)
 - Sanitary wet well openings above influent channel and floor hatches (19 ft x 5 ft with screen below)
 - Potentially the water-tight doors into the storm and sanitary wet wells which requires further coordination with GLWA due to recent leakage issues with these doors.

Figure 3-2
Oakwood Storm and Sanitary Wet Well Access Points (PC-755 Record Drawing D-04-08-407)

- Permanent ventilation system capacity and capability
 - Supply fan dedicated to the wet wells (one fan for east and one for west)
- Allowable water source and location of connection, assuming contractor will be permitted to use secondary water for use in the cleaning process.

In addition, acceptance criteria in form of qualitative description of how clean the wet wells must be to comply with the specification.

3.1.1.1 Cleaning System/Approach Evaluation – Extent of Allowable Use of Sanitary Pumps

The four sanitary pumps are equipped with hard metal components to maximize service life when pumping high solids pumpage. However, the nearly continuous duty of these pumps for this critical application likely is not aligned with a contractor using the pumps to convey solids downstream (into collection system and ultimately to the water resource recovery facility [WRRF]). Based on discussion at the GLWA TM workshop No. 2 held on April 19, 2023, GLWA agreed with the cleaning contractor will not be allowed to use the sanitary pumps but will be able to discharge decant water to manhole along the sanitary system.

A consideration will also be the potential to overload or starve the pumps due to an excessively high-debris concentration with the potential to clog the pumping units with potential for associated overloads.

As coordinated with GLWA in TM workshop No. 2, the cleaning contractor will be required to remove the accumulated debris, likely with vactor truck, dewatered/decanted and solids disposed off-site. The removal methods and/or associated constraints will be further defined based on the Pullman meeting noted in the Next Steps section.

3.1.1.2 Cleaning System/Approach Evaluation – Potential to enhance access/wet well limited clearance impact

The existing access methods to enter the wet wells with personnel and equipment are described above. The ability to increase the accessway size is limited by the configuration of the pump station as described in this section.

An important consideration is the limited value that greater accessway size may offer due to the constraints within the wet wells due to pumps, splitters, fillets, etc. as described below.

Wet well limited clearance constraints:

- Storm wet well as shown in **Figure 3-3**
 - 8-inch flushing water header at ~11 ft above wet well floor on outside wall. The distance from the flushing water header to the pump intake (bell) is about 6 ft. However, from toe of sidewall fillet to pump bell is about 5 ft on the side by the flushing water pipe.
 - There are splitters under each pump bell. Distance between splitters (parallel to line of pumps) is about 2 ft.
 - Distance between pump bell and sanitary trench is about 3 ft.
 - Between the sanitary trench and the East/West dividing wall is a 45-degree fillet.
- The sanitary wet well is also filled with 45-degree fillets at the perimeter walls, splitters below the pumps and a vertical baffle wall to direct flow to pump which greatly limit equipment from maneuvering in the limited clear area with the potential to hit a pump.

Figure 3-3
Oakwood Storm Wet Well Clearance Constraints (PC-755 Record Drawing D-04-08-405)

Considering these clearance constraints it appears that the clear distances available for equipment in the storm wet wells are within the limits of the hatch size provided above the expansion zone. In addition, it is clear that the maneuverability of cleaning equipment will be constrained by the wet well clearance constraints in both sanitary and storm wet wells.

Ability to increase size of wet well openings:

The storm wet well access enhancement evaluation focused on the existing 6 ft x 10 ft hatch of each expansion zone. The vertical shaft for this accessway is limited to the south by the surge relief box culvert (Oakwood record drawing D-04-08-306) and to the north by the jib crane foundations (D-04-08-307). Therefore, evaluation concluded that the wet well openings are maximized to extent feasible and aligned with the working clearances in the wet well.

For the sanitary wet well the value of opportunities to enhance access are constrained by available working clearances for equipment below which led to the finding that there is not a significant benefit to increasing the size of openings.

3.1.2 Cleaning System/Approach Evaluation - Long-term activities

The long-term cleaning system/approach evaluation is focused on two key elements, first development of an SOP to delineate the recommended steps and processes to follow for

intermittent cleaning requiring supplemental equipment and entry as well as flushing system sourced cleaning after each wet weather event. Second, utilize the improved storm wet well flushing system and associated sanitary pump operation to minimize the frequency of required cleaning that will be integrated into the SOP.

The SOP will be developed in the final design phase and will likely be focused on an intermittent cleaning method utilizing slurry pumps to facilitate removal of the debris from the wet well given the limited working clearances for equipment within the wet wells.

The improvements to the storm wet well flushing system, based upon the evaluation performed as part of this project, will be incorporated into the SOP to facilitate cleaning of the storm wet well after each storm event using the flushing water without entry into the wet well. The intent of the flushing system will be to reduce the frequency of manpower intensive cleaning within the wet well. The evaluation of the flushing system as part of the physical model study will provide insights on operation that will be captured in the SOP.

3.2 Storm Pump Rehab Evaluation

The storm pump rehab evaluation consisted of several sub-evaluations which sum to the overall evaluation of the required components to be rehabilitated, the determination if grease lubrication is technically feasible coupled with conceptual consideration of how to accommodate systems in the pump station and assessment of if a path forward focused on the storm pump work items bid as a stand-alone contract is justified from cost and/or schedule perspective.

3.2.1 Evaluation of Pump Manufacturers to Execute Storm Pump Rehab

This storm pump manufacturer evaluation extended beyond the original manufacturer to enhance competition given hydraulic design will not be changed and GLWA's concurrence to consider others.

The pump manufacturers/pump shops which may be capable to perform the storm pump rehabilitation work (including the modification to bearing grease lube system) were assessed based on three key criteria: large vertical suspended pump rehabilitation experience, custom grease lubrication system engineering/fabrication experience, and ability to factory test the rehabilitated pumps.

The following manufacturers/shops were contacted:

- Flowserve
- Johnston/Sulzer
- Xylem Flygt AC-Custom Pump (OEM)
- Kennedy Industries
- Fairbanks Nijhuis (Pentair)

A summary of the evaluation findings is provided in **Table 3-1**. It is clear from this evaluation that the number of qualified entities to perform the work is limited. In addition, the OEM manufacturer, Xylem, will have an advantage over the other listed manufacturers due to their familiarity with the pump design and fabrication details of the installed pumps.

Table 3-1 Pump Manufacturer/Shop Evaluation Summary

Pump Manufacturer/Shop	Large VS Pump Rehab Experience?	Grease Lube System Design/Fab. Experience?	Factory Test Capability?	Notes
Flowserve	Yes	No	Not determined	
Johnston/Sulzer	Yes	Yes	Yes	
Xylem Flygt AC (OEM)	Yes	Yes	Yes	
Kennedy Industries	Yes	No design experience	No	Plans to team with Xylem Flygt who they represent locally
Fairbanks Nijhuis	Yes	Yes	Required third party test location if performance test	At this time, uncertain if third party test facility can test pumps of this size

Based on the results of the evaluation the following pump manufacturers are recommended to be listed in the storm pump rehabilitation specification: Johnston/Sulzer, Xylem Flygt AC-Custom Pump and Fairbanks Nijhuis. At the time of this writing evaluation of the type and extent of factory test to be conducted was under evaluation. If determined a performance test is required this may result in Fairbanks Nijhuis not being able to meet this requirement.

3.2.2 ST-5 Rehabilitation Findings, Lessons Learned and Conclusions

ST-5 (large pump) was removed from the pump station in pieces (due to vertical clearance constraints) and transported to Kennedy Industries (KI) for inspection, cleaning, dimensional clearance tolerance check and rehabilitation in Spring 2022. This pump is assumed to be representative of all the storm pumps and thus will be the basis to determine rehabilitation scope.

KI's work included all pump components up to the stuffing/packing box excluding the discharge head. Conversion to grease lubrication of the bearings was not part of the work. A report summarizing the inspection findings and components in need of repair is included in Appendix A for reference.

Supplemental photos to their report were provided by KI showing the quantity of debris accumulated in the bearing lubrication grooves which confirms the plugging maintenance challenges with the water lubrication system discussed in Section 2 coupled with system operation as shown in **Figure 3-4**.

Bearing groove filled
with debris (typ)

Figure 3-4
ST-5 representative bearing grooves filled with debris (photo courtesy of KI)

ST-5 was installed but unable to operate for about 1 year based on discussions with GLWA maintenance staff. In that time mud accumulated (caked on) the upper side of the impeller vanes. This is of concern from a rotor balance perspective. This highlights the need to regularly operate the pumps to avoid sediment depositing on and bonding to the top-side of impeller vanes. The mud accumulation is shown in the **Figure 3-5** which also includes some debris from other components loosened by the disassembly process.

Figure 3-5
ST-5 Impeller with mud deposited on top side of vanes (photo courtesy of KI)

From the Design Team discussions with GLWA maintenance staff the Design Team learned that KI was directed to replace all the Thordon SKL line shaft and bowl bearings with bronze-backed cutlass (cutless) rubber bearings given GLWA's good success with this bearing type on other wastewater applications.

The following conclusions can be drawn from the KI's work:

- The following components will require replacement in the rehabilitation of each storm pump: all bowl and line shaft bearings and potentially shaft sleeves (if determine alternate material to existing ASTM A276 Type 410 stainless steel shaft sleeves optimized for grease lubrication would enhance reliability and reduce maintenance).
- The bearing replacement material of construction recommendation is focused on providing a bearing of similar stiffness to the Thordon SKL (to minimize impact to pumping unit natural frequency to potential excitation source separation margins). The replacement will also be well suited for grease lubrication and durable. This will be a bronze bearing with the alloy to be determined in the basis of design (BOD) phase.

These rehabilitation items will be included in the storm pump rehabilitation specification as part of the contract documents.

3.2.3 Evaluation of ST-5 field modification feasibility for grease lube system components

The evaluation of feasibility to modify recently rehabilitated ST-5 in the field (in pump station motor room) to accommodate grease lubrication modifications included consideration of the following:

- Pump will require nearly complete disassembly for the modifications
- Machining of components, precision drilled and tapped holes, hydraulic press removed/installed parts and other machining is anticipated to facilitate accommodation of grease lubrication system components
- Tight tolerance fits required to meet reliability, functionality and efficiency guiding principles
- Line shaft and pump bearings will require replacement to bronze bearings
- Ample space will be required for laydown and work areas
- Pump Station operation must be maintained throughout construction

Based on this evaluation the Design Team concluded that field modification of ST-5 will not be feasible due to the following: observation of staff activities and storage functions in the storm pump motor room during the Design Team ride-along site visits; machining equipment required to be brought to the site (supplied power and anchored to floor) and limited working space (which must

be in hook reach of the bridge crane). Therefore, the pump must be sent off-site to be modified to accommodate the grease lube system components.

3.2.4 Grease lubrication system technical feasibility evaluation

To address the cooling/seal/lube water system plugging and storm pump seizing due to debris accumulation in the enclosing tube with resultant pump down time and reduced reliability described in Section 2, the technical feasibility to convert the existing water lubricated line shaft and bowl bearings to grease lubrication was evaluated and investigated with a focus on the following:

- Discussion with grease lube experienced pump manufacturers
- Past use of this lubrication system in vertically suspended (VS) pumps
- Investigation of similar applications in southeastern Michigan equipped with grease lubrication with several discharging to receiving streams
- Adequate space in the pump station for the grease lubrication systems with sufficient room for maintenance access while minimizing impact to pump/motor maintenance access

A summary of the findings from each of the evaluation elements follows:

- Experienced pump manufacturer input: Universally agree that this conversion is feasible even though unusual.
 - Manufacturers added that it is typical grease lube to be applied for intermittent (on demand) use systems such as the storm pumps
- VS pump grease lube experience in the pump industry: Confirmed
- Similar VS grease lube equipped applications in SE Michigan were identified including the following:
 - Several MDOT stations conveying flow to Detroit and Rouge Rivers
 - Wayne County CSO PSs discharge to interceptor then pumped to Rouge River tributaries
 - Wayne County airport pump to ponds which are released to surface water system in warmer months

In conclusion, the modification of the storm pumps to equip with grease lubricated bearings has been determined to be technically feasible. Redundancy, configuration, location and other associated evaluations for this system are covered in the following sections.

3.2.5 Storm Pump Grease Lubrication System Redundancy Evaluation

The number of grease lubrication systems relative to the number of storm pumps was evaluated with vision provided by the project guiding principles. As part of this evaluation, in the February 20, 2023 meeting with GLWA pump maintenance staff the Design Team learned that past experience with a grease lubrication system that served multiple process pumps led to problems with resultant loss of all process pumps greased by the shared lube system. Ultimately the process pumps were modified to no longer be served by a shared lubrication system.

In the evaluation the Design Team determined that commercially available lubrications systems, such as those manufactured by Farval, are limited on the number of process pumps which can be served by a single lubrication system. For example, the CS2000 system, under consideration for this application, would be able to serve two storm pumps. However, both units would be lubricated at the same quantity and time which may not be required if storm pump runtimes vary.

A comparison of advantages and disadvantages of dedicated lubrication systems versus shared lubrication systems is provided in **Table 3-2**.

Table 3-2 Advantages and Disadvantages of Dedicated vs. Shared Grease Lubrication Systems

Grease Lube System Redundancy	Advantages	Disadvantages
Dedicated grease lubrication system to each storm pump	- Grease lube system redundancy equivalent to storm pumps - Improved operational flexibility - Simplified control and operation of this support system - Grease supply quantity would be pump specific, no excess usage - Access impacts to storm pumps/motors maximized by avoiding grease pipe obstacles between storm pumps - Minimize length of grease piping - Minimizes single points of failure	- Increased capital cost - Additional units to maintain
Shared grease lubrication system to multiple storm pumps (2 storm pumps)	- Reduced capital cost - Lower quantity of units to maintain	- Storm pump redundancy limited by grease lube system - Increased control complexity - Grease piping likely access obstacle

Despite the capital cost increase with storm pump dedicated grease lubrication systems, the non-cost advantages vs. disadvantages listed coupled with past GLWA pump maintenance experience have led to the recommendation to provide a dedicated grease lube system to each storm pump. Through discussions with GLWA staff responsible for pump maintenance and as discussed further at TM workshop No. 2 held on April 19, 2023, the use of a dedicated grease lube system for each storm pump was agreed upon.

3.2.6 Evaluation of Storm Pump Grease Lubrication System Location

There are two locations in the storm pump station (PS) available for new grease lube system equipment: first, the intermediate level in vicinity of each pump with the specific location to be selected in coordination with GLWA in preliminary design phase; second, the storm pump motor room which was initially eliminated due to probable conflicts with storage functions, staff use of the room (electrical techs “home base”) and the inability to place equipment inboard of the pump motors due to potential for access limitations for vehicles stored or utilized in the room. However, GLWA operations staff noted in the February 13, 2023 workshop that the staff use of the area is temporary and stored items can be relocated. The areas utilized for storage and by staff were primarily located between the storm pump motors as well as at the north end of the truck access way in center of PS. Therefore, the motor room is a viable option which is further evaluated in this section.

Based on general review of the two PS floors the Design Team assessed, at a conceptual level, that sufficient room would be available on each floor near each pump while minimizing the impact to existing equipment maintenance access. This will be evaluated in further detail after specific model and configuration are known with application specific dimensions and number of units selected.

A comparison of advantages and disadvantages of the two locations available to house the grease lubrication systems is provided in **Table 3-3**.

Table 3-3 Advantages and Disadvantages of Grease Lube System Location: Conceptual Evaluation - Storm Pump Motor Room versus Intermediate Level

Location	Advantages	Disadvantages
Storm pump motor room	▪ Readily accessible with bridge crane and grease re-supply cart (with manual grease pump and grease) ▪ Somewhat closer to the power source ▪ Typical to locate lube systems at the “at grade” level. ▪ Closer to control room for intermittent inspection	▪ Reduces the available space for other functions in the room (storage, etc.) ▪ Further from the bearings resulting in longer grease lines.
Intermediate level	▪ Lower “traffic” area in terms of staff, storage functions and no vehicle access ▪ Closer to the bearings, shorter grease lines	▪ Requires use of existing hatch and bridge crane to lower grease re-supply cart (or grease to the cart) to intermediate level to resupply grease (additional maintenance effort) ▪ Could restrict access to stuffing box which will not be required as present conditions with limited adjustments required ▪ Further from power source: anticipate small increase in conduit and wire length at greater cost ▪ If a monumentally high wet well water surface elevation, remote potential to partially flood this level which would damage these systems

Based on the evaluation summary in **Table 3-3** and no distinctly higher cost for one location, the Design Team recommends the storm pump motor level as the preferred level for further evaluation in the next phase based on the number of units selected and the application specific footprint to be developed in further collaboration with GLWA. As discussed and agreed upon at TM workshop No. 2, the design team will proceed with the storm pump motor room as selected location for the grease lubrication systems.

3.2.7 Conceptual Evaluation of Storm Pump Enclosing Tube Bottom Seal

In addition, given the application specific challenge of debris migrating into the enclosing tube the Design Team began investigation of the probable sealing method for the bottom of the tube to minimize the potential for this to occur in the future. The concept, at the time of this writing, includes specifying a custom engineered sealing solution manufactured by a seal specialty company, such as Chesterton, to obtain a configuration for optimized longevity and functionality. This would likely include two lip seals (one to minimize wastewater/debris entry into the tube and other oriented to minimize grease release out of the tube) along with a throttle bushing to discourage debris from contacting the seal face to maintain seal integrity. Further evaluation will be performed as the design progresses.

3.2.8 Evaluation of Storm Pump Existing Grease Lubricated Bearing Connection to Lubrication System

Each storm pump is equipped with one line shaft bearing which is not water lubricated, rather it is grease lubricated. This bearing is located on each storm pump between the top of discharge head and bottom of motor approximately at the elevation of the storm pump motor room floor.

The bearing is presently manually greased via a grease gun connected to a zerk fitting on the motor stand to allow grease to be applied without entering the motor stand window.

The incremental capital cost increase in cost to connect this bearing to the grease lube system would be negligible (estimated by bearing lubrication manufacturer to be \$200/system) if determined early in the design.

A comparison of advantages and disadvantages of connection of the grease lubrication system to the existing grease lubricated bearing is provided in **Table 3-4**.

Table 3-4 Advantages and Disadvantages of Connecting Grease Lubrication System to Existing Grease Lubricated Bearing

Existing Grease Lube Bearing Lubricant Source	Advantages	Disadvantages
Connect grease lubrication system to existing grease lubricated bearing	- One system utilized to lube all pump bearings - One type of grease applied to all pump bearings - Reduce the bearing maintenance by focusing only on the grease lube system - May be an opportunity to enhance the seal arrangement at the shaft to reduce grease leakage	- Change from present maintenance procedures - Nominal capital cost increase to add grease lubrication point in the grease lube system
Do not connect grease lubrication system to existing grease lubricated bearing	- Maintain present procedure which is part of the normal PM activities - Confirmed technically feasible with Xylem Flygt.	Potential for multiple grease lubricants to lube pump bearings

Based on the evaluation summary in **Table 3-4**, the Design Team recommends the storm pump bearing located between the discharge head and the motor be connected to the lubrication system for system simplicity, higher reliability and centralized maintenance and a common lubricant for all pump bearings. As confirmed in TM workshop No. 2, GLWA agreed to adding this bearing to the central grease lube system lubricated bearings.

3.2.9 Evaluation of the Seal/Cooling/Lube Water System Modifications

The modification of the storm pumps to be equipped with grease lubricated line shaft and bowl bearings will eliminate two of the three functions of the water system (seal and lube). This is due to the lubrication conversion from water to grease coupled with the stuffing box seal water no longer

being required since the enclosing tube will no longer contain water and the elevation of the stuffing box is above the maximum water surface elevation and packing will no longer be needed.

The existing seal/lube/cooling water configuration the water pressure remaining at the connection to the storm pump stuffing box/pump column and bowl bearings was expected to be too low under maximum operating conditions. As a result a small booster pump was used to increase the water pressure to the minimum required. Booster pumps were each selected for a rating of 10 gpm at 85 feet total head boost.

From the preliminary investigation, it appears that the existing booster pump may not be required when the storm pumps are modified to grease lubrication, but this will be verified during preliminary design.

The remaining function of the system will be cooling water for the motor thrust bearing. This function requires 8 to 9 gpm at water temperature less than 85 °F at pressure no greater than 100 psi according to the shop drawings. This cooling water requirement was discussed with Ideal Electric (motor OEM) who indicated that a pressure of 30 psi at the cooler inlet (near top of motor) is suitable for the application. Ideal acknowledged pressure could likely be even lower and not impact cooling function as long as flow rate is maintained.

Alternatives for the motor thrust bearing cooling water disposal are summarized and evaluated in Sections 4 and 5, respectively.

3.2.10 Evaluation of Storm Pump Rehab Contract Separate from Remainder of Project Work

The evaluation of separating the storm pump work from the reminder of the project as a stand-alone set of contract documents, to be bid before the reminder of the project, focused on the following:

- Feasibility to separate this work from the remainder of the project
- Potential cost efficiencies
- Potential schedule efficiencies

3.2.10.1 Scope of systems/sub-systems included in the storm pump work

The storm pump systems/sub-systems envisioned to be included in dedicated storm pump contract include the following:

- Storm pump removal, rehabilitation/modification and re-installation, including associated factory testing
- Modification of the storm pump motor thrust bearing cooling water system which will replace a portion of the cooling/seal/lube water system dedicated to each storm pump

- Revisions to the Ovation programming to accommodate new monitoring and control features for the grease lubrication system.
- Revision to Ovation programming to reflect the GLWA selected control strategy revisions to constrain rehabilitated pump operation to within AOR (outside the unstable portion of the curve). This includes revision to wet well operating range and acceptable speed range for both pump sizes.
- Electrical system revisions to provide power, and instrumentation and control (I&C) conduit and cables for the new grease lubrication system equipment and instruments for each pump.

3.2.10.2 Contract Options

The two design-bid-build delivery contract options are as follows: first, general contractor sourced contract with the pump manufacturer and other specialty contractors as subs to the general. Second, a contract direct to the pump manufacturer which would be responsible for the full scope of work. This would include several work items that are not normally furnished by the pump manufacturer resulting in several subcontractors all contracted to the pump manufacturer.

A summary of the comparison of the two contract options evaluated on qualitative basis follows:

- Pump manufacturer discussions: Pump manufacturers have indicated that they are not comfortable with the direct to GLWA contract due to being responsible for several work elements which are not their specialty. Uncertain if pump manufacturers would be willing to take on the added risk and responsibility to connect and integrate the pumps into the support systems.
- Pump manufacturer direct contract with GLWA: Based on evaluation of pumping equipment pre-purchase for a GLWA water treatment plant improvements project, focused only on the equipment, there is significant concern that the probability of not reaching consensus on terms and conditions is high which could lead to a no-bid condition for qualified manufacturers.
- Project is well suited for a general contractor to perform with multiple subcontractors and the pump manufacturer's work being the majority of the project.

Based on this evaluation summary the contract configuration which is most likely to be successful is the general contractor contract. The analysis which follows has assumed that this would be the contract arrangement.

3.2.10.3 Conceptual Cost Differential – In Overall Contract or Separate Contract

The conceptual cost differential for the work to be in the overall construction contract versus in a separate stand-alone general contractor executed contract is linked the several key factors:

- When the work would be completed (potential to save on escalation)

- Potential major savings associated present continuous operational cost: potable water, downstream of a backflow preventer, 24/7 to the cooling/seal/lube system (based on estimated average flow rate of about 15 gpm/pump observed at rotameters on ride alongs and 2023 water rate of \$13.41/1000 gallons (combined water and sewer charges) this service uses roughly 63 million gallons per year at approximate annual cost of \$846,000.)
- Assumed indirect costs for separate contract for storm pump work would be comparable to those if performed as part of the overall cost.
- Maintenance cost differential not considered given the continuous cooling/seal/lube water supply operating mode appears to have greatly limited if not stopped the maintenance demands for this water system since no longer seizing the pumps or require extensive manual intervention to return to full functionality if system were to plug or seize.
- Determined that the other LCCA factors are essentially equal between the two contract options.

On a conceptual level the cost differential would be a savings compared to incorporation in the overall contract on a qualitative basis, without consideration of the cost of preparing a separate design package or overseeing the work (resident project representative (RPR) and general services). This is based on reduced duration of operating cost for water continuously supplied to the pumps and reduced escalation.

However, the cost differential differences, which qualitatively support a separate contract, were secondary to the identified need described in Section 3.2.10.4 to begin this element of the work as soon as possible due to the overall duration required to perform the pump rehab relative to planned overall project construction schedule.

3.2.10.4 Conceptual Schedule Differential – In Overall Contract or Separate Contract

The schedule comparison of the two contract options is based upon the timing of the overall project construction phase to the estimated duration of major work tasks for the storm pump separate contract.

Several assumptions are required to compare the two schedules:

- Only one storm pump can be out of service at a time to maintain seven units available for combined sewage conveyance, if needed. As a secondary assumption, two pumps out of service at a time after the first pump was investigated. The maximum number of pumps operating in the larger wet weather events was evaluated and is summarized in TM-15.
- The overall project construction phase timing will remain as scheduled, at the time of this writing, (Notice to proceed (NTP) July 31, 2025 to completion January 31, 2029). This schedule assumption will be further reviewed as the design progresses. However, it was used as a basis for comparison to a separate contract herein.

- Several tasks required prior to starting the rehab work as a separate contract, each of which require time as follows: (design phase (assumed 9 months), bid phase (assumed 3 months), contract approval (assumed 300 days as indicated in contract))
- The major steps of the storm pump rehab/modifications for each pump will include the following (with Xylem estimated durations) with several assumptions:
 - Pump manufacturer engineering: 8 weeks
 - Submittal review phase: 10 weeks
 - Pump removal and transport: 2 weeks (1 week each)
 - Pump rehabilitation/modification (includes clean, disassemble & inspect): 26 weeks for first pump and 20 weeks for subsequent pumps (based on Xylem furnished estimates)
 - Pump factory testing: 3 weeks
 - Allowance for witness of factory testing (assume factory testing witnessed): 3 weeks
 - Pump transport and installation: 3 weeks (includes 1 week for transport)
 - Connection and testing of support systems (cooling water, electrical, I&C) assuming all work that can be done with pump removed is performed during pump rehab time: 3 weeks
 - Field commissioning (assume not wait for wet weather event to complete commissioning): 2 weeks
- Estimated total time for first pump rehabilitation/modification return to operation from Design Team NTP: 151 weeks.
- The duration for each subsequent pumps would exclude the engineering and submittal review phases resulting in estimated duration per pump of 36 weeks.
- Total estimated time for all pumps including the design, bid, contract approval and work on each pump summarized above: 403 weeks (if one pump rehabilitated/modified at a time). This duration could be reduced substantially if two pumps could be rehabilitated simultaneously. In addition, may be opportunities for factory test duration dependent on required tests and extent of witness requirements.
- The support system modifications would occur within the storm pump rehab task durations stated above to extent feasible unless indicated otherwise. Three weeks estimated for connection of support systems after pump and motor reinstalled.

- The above schedule approximation does not account for Michigan frost law transport constraints which could extend the schedule delineated above.
- The duration required if rehabilitate/modify one storm pumping unit at a time and start at end of the BOD phase (Task C) would extend beyond the scheduled construction completion date.

The above analysis demonstrates that the ability to facilitate storm pump rehabilitation/modification work item completion prior to the overall construction project would not be feasible if the work on one pump is completed prior to starting on the next without substantial extension of the planned construction schedule.

The separate contract schedule starting final design immediately after Task C completed, if two pumps are rehabilitated/modified after the first pump, was compared to the current construction schedule in TM workshop No. 2 demonstrating a time savings of approximately three months inclusive of associated assumptions. Based on the limited time savings provided coupled with the added cost of a separate contract, at TM workshop No. 2, GLWA decided not to pursue a separate contract for the storm pump work. However, identified that discussions with EGLE and other GLWA stakeholders are needed to determine if two pumps can be removed at a time as part of the BOD phase.

4.0 Description of Alternatives

Alternatives analyses were focused only on the cooling water disposal element of the storm pump rehabilitation/modification improvement item.

4.1 Storm and Sanitary Wet Well Cleaning

Not used.

4.2 Storm Pump Rehabilitation/Modification

Several alternatives were evaluated to determine the recommended method to dispose of the cooling water required to address the process needs of the motor thrust bearings. This evaluation was required due to the change from water lubricated to grease lubricated bearings which will result in the water flow path also being modified. The disposal/use of the cooling water in the existing configuration will no longer be feasible since thrust bearing cooling water will no longer be discharged to the stuffing box or enclosing tube since now filled with grease as described above.

4.2.1 Motor Thrust Bearing Cooling Water Disposal Alternatives Description and Evaluation

The following alternatives were evaluated on a technical and permitting basis to determine which would be viable and most closely aligned with the project guiding principles.

Alternative A

The possibility of discharging the spent cooling water from the motor heat exchanger to an existing pipe in the yard that conveys flow to the storm water pond in front of the pump station. It was thought that this was a reasonable solution because this water source was close to potable water with only a slight increase in temperature. However, it was assumed that this likely would be a permitting challenge to convey process utilized water to environment and thus was not developed into a full alternative.

Alternative B

For this alternative, the cooling water piping will be redirected to discharge to the process drain system on the intermediate level. The process drains are located between the storm pumps. The drains direct the collected flow to a sump pit equipped with a pump located on the intermediate level which discharges to a 6-inch sanitary pipe at elevation 98 ft.

GLWA raised concerns with the potential for the intermediate level to flood if the sump pump stops working and asked that a backup pump be provided. The accommodation of the second pump was discussed at TM workshop No. 2 on April 19, 2023 and then further with operations at follow-up meeting to the workshop on May 3, 2023. It was agreed that a spare pump would be provided above the sump pit, connected to the sump pump discharge piping to operate only if triggered by a flood condition. This improvement would also include a level sensor to alert if the level is above the sump pit meaning the duty pump is not functioning properly.

The existing sump pump (P-3) is rated at 40 gpm and is listed as ½ horsepower according to record drawings. The sump is 5-ft diameter and serves the process drain system for all eight storm pumps. The existing sump pump will require replacement with a new unit rated preliminarily at 63 gpm at 18 ft total head. It is expected that a submersible pump is commercially available for that rating with no more than 1 horsepower motor. It appears that a Hydromatic SPX50 is a viable selection for these conditions.

Alternative C

This alternative is similar to alternative B except that the 1-inch pipe would be directed to the floor drain system in the motor room level. The advantage to Alternative B is that the water is discharged by gravity at the motor room level and no modifications would be required to the sump pump system. The concern with this option is that there are only four process drains (PDs) on the motor room floor, and they are in areas that are presently being used by GLWA for other tasks including storage with the drain piping interfering with those functions. In addition, the configuration of the PDs in this floor are not adapted to continuous process drainage and spillage out of the drain inlet is anticipated. Using the existing PDs near each pump on the intermediate level makes more sense since the intermediate level is not a multi-functional space.

Alternative D

Alternative D evaluated in concept if possible to use the existing motor thrust bearing heat exchanger and existing cooling water booster pump with eight motor-dedicated new appropriately sized radiators with electric motor driven fan to dissipate the heat from each storm pump motor thrust bearing. In this option the secondary water supply would be replaced with a water and corrosion inhibitor or ethylene glycol mixture that would be recirculated in much the way automobile engines are cooled. This alternative was not fully developed due to concerns with conflicts with project guiding principles including reducing maintenance, simplifying operation, and enhancing reliability for a pumping system with limited run time. Additionally, this concept appeared to be significantly more complex than the other alternatives, thus not desirable. Further, the waste heat would have been blown into the motor room which could be detrimental at certain times of the year.

5.0 Alternatives Analysis

5.1 Storm and Sanitary Wet Well Cleaning

Not used.

5.2 Storm Pump Rehabilitation/Modification

5.2.1 Motor Thrust Bearing Cooling Water Disposal Alternatives Evaluation

The evaluation of motor thrust bearing cooling water disposal was covered in part in the description of the alternatives in Section 4.0. Based on the evaluation summary, the recommended alternative storm pump dedicated cooling water system modification is Alternative B (water discharge to intermediate level sump pit and pumped to sanitary pipeline for disposal at WRRF) given its alignment with guiding principles with focus on reliability, simplicity and maintenance minimization.

If the cooling water booster pumps are determined to no longer be required, the cooling water system will be redesigned and significantly simplified. Confirmation of minimum potable water system pressure is required to determine if booster pumps will no longer be needed. This will be determined in preliminary design phase.

6.0 Life Cycle Cost Analysis

Not used.

7.0 Recommendations and Key Decisions

The major recommendations for the wet well cleaning and storm pump rehab are summarized in this section. Greater detail is provided in the preceding sections.

7.1 Storm and Sanitary Wet Well Cleaning

Near-term: In the final design phase a wet well cleaning specification will be developed to define the requirements for cleaning the two storm and two sanitary wet wells as part of this project.

Long-term: Also in the final design phase a SOP will be developed to incorporate the storm wet well flushing system/sanitary pump operation cleaning after each wet weather event as well as the intermittent cleaning procedures which will require staff entry and the use of supplemental portable equipment to conduct the cleaning.

7.2 Storm Pump Rehabilitation/Modification

The following pump manufacturers are recommended to be listed in the storm pump rehabilitation specification: Johnston/Sulzer, Xylem Flygt AC-Custom Pump and Fairbanks Nijhuis.

Recommended scope of rehabilitation includes replacement of the shaft sleeves, line shaft bearings and bowl bearings.

Recommend proceeding with grease lubrication system which is technically feasible for the application.

Recommended scope of grease lubrication system to consist of:

- Dedicated lubrication system for each storm pump
- Grease line to each line shaft and bowl bearing
- Food grade grease
- Inclusion of the existing grease lubricated bearing between the stuffing box and the motor
- Recommend reconfigure cooling water system for motor thrust bearing to be connected to the intermediate level PD system and replace the sump pump to meet new conditions of service.

Recommended to provide a dedicated grease lube system to each storm pump based on evaluation above and GLWA experience.

Recommended the storm pump motor level as the preferred location for further evaluation in the next phase based on the number of units selected and the application specific footprint to be developed in further collaboration with GLWA.

Recommended the storm pump bearing located between the discharge head and the motor be connected to the lubrication system for system simplicity, higher reliability and centralized maintenance and a common lubricant for all pump bearings.

Recommend proceeding with a separate contract for the storm pump rehab due to the construction phase duration being insufficient to incorporate the time required to perform the work.

7.3 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

- Sanitary pumps will not be utilized during the cleaning process performed by outside contractor as part of the construction contract.
- Storm pump improvements: One grease lube system per storm pump; grease lube systems located on motor room level; connect the one existing grease lube bearing to the new grease lube system; and cooling water disposal alternative acceptable but will require sump pump backup included in Next Steps section.
- Storm pump rehabilitation/modification to be performed in one construction contract. Need to include time limits and statements to provide submittals in a limited time from notice to proceed and remove first storm pump as soon as possible and rehab two pumps at a time (two pumps at a time requires other stakeholder buy-in as included in the Next Steps section).
- GLWA noted agree with CDM Smith recommendations for pump manufacturers to list for pump rehab/modification.

8.0 Next Steps

The items which require advancement/further development as the design process advances include the following:

8.1 Storm and Sanitary Wet Well Cleaning

- Determine if watertight door access will be permissible for the contractor's cleaning activities based on input from GLWA.
- During the BOD phase, discuss the recently completed storm and sanitary wet well cleaning performed by Pullman and WSI to understand methods and constraints based on their experiences.
- Consider how include cleanup of the upstream pinch valve area to minimize the need for additional cleaning required for the work in this area in the overall cleaning specification.

8.2 Storm Pump Rehabilitation/Modification

- Obtain grease lubrication system application specific sketches from Farval. Incorporate opening up (particularly electrical/control panels) configuration somewhat to enhance access over a standard baseplate mounted system.
- Provide a list of the common maintenance requirements to GLWA operations to allow understanding as requested during workshop held on February 13, 2023.

- Further discussion of the degree of automatic operation of the grease lubrication system either as a primary lubrication step or as a back-up to manually initiated lubrication cycle conducted on a regular time interval.
- Determine if a hold point will be required at the factory to allow inspection of the new components prior to installation due to inability to inspect after assembled as noted by GLWA staff in the February 20, 2023 meeting.
- Further evaluate required maintenance access to the storm pump discharge head and motor in collaboration with GLWA to determine the locations where the new grease lube system could be located.
- Further develop the design concept for seal at bottom of enclosing tube including discussions with specialty seal manufacturers.
- Investigate risk of storm pump seals drying out in the enclosing tube if pumps are off for several months coupled with materials selection to minimize the potential for the resultant seal damage to occur.
- Determine recommended line shaft bearing, bowl bearing and shaft sleeve materials of construction.
- Determine the focus areas of required storm pump factory testing. In particular is a performance test warranted when no change to the hydraulic design.
- Determine if two storm pumps can be removed simultaneously for rehabilitation/modification based on coordination to be completed with EGLE and GLWA.
- Further evaluate how to expedite the storm pump rehabilitation/modification work. As part of this evaluation gather information regarding number of pumps simultaneous operating for the larger events.
- Obtain product data for furnished sump pump in intermediate level sump pit.
- On the intermediate level of the storm pump station, incorporate a second sump pump located above the sump to serve as an emergency backup to the new pump which will replace the existing sump pump.
- Investigate minimum potable water pressure for this portion of the distribution system to determine if existing cooling water booster pump could be removed. This includes the ongoing coordination for the concept and device recommended by design team and GLWA acquiring and installing the pressure monitoring/recording equipment.

- All new and/or modified process mechanical loads will be coordinated with electrical to verify available power system capacity, available voltages, and location of starter/VFD/breaker needed for each piece of equipment.

Mr. Hall:

Attached are photos with descriptions of the parts in need of repair or replacement. If you have any questions, please do not hesitate to contact us.

Sincerely,

Mike Horn

Repair Center Manager
KENNEDY INDUSTRIES, INC.

PUMP

- Pump at Kennedy facilities.

IMPELLER

- Impeller is in good condition and will be reused.

SHAFTS

- Intermediate shaft T.I.R. is 0.002" and within specification.
- Head shaft T.I.R. is 0.003" and within specification.
- Both shafts are in good condition and will be reused.

DIFFUSER

- Register to diffuser bowl ID clearance is 0.010" and within specification.
- Diffuser is in good condition and will be reused.

UPPER BEARING

- Inside of upper bearing is plugged with hard product.
- Bearings will be replaced with upgraded bronze-backed, cutless bearings to restore proper operating clearance.

LOWER BEARING

- Lower bearing will be replaced with upgraded bronze-backed cutless bearing to restore proper operating clearance.

ENCLOSING TUBE

- Tube was cut at removal.
- Weld and blend to restore surface conditions.

STUFFING BOX

- Stuffing box is worn.
- New stuffing box bearing will be manufactured and installed to restore proper operating clearance.

STUFFING BOX BEARING SLEEVE / PACKING SLEEVE

- Sleeves are worn and pitted.
- Sleeves will be machined to restore concentricity and proper surface finish.

SPYDER BEARING SLEEVE

- Spyder bearing sleeve is worn and pitted.
- Sleeve will be machined to restore concentricity and proper surface finish.

LOWER BOWL SLEEVE

- Lower bowl sleeve shows minimal wear.
- Sleeve will be machined to restore proper concentricity.

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Julie Aichler, CDM Smith
Steve Fehniger, CDM Smith*

Date: June 1, 2023

*Subject: TM-4 Oakwood Screw Conveyor & Grinder System Modifications (OKW-SCR-2)
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The screen facility at the Oakwood Combined Sewer Overflow (CSO) Retention Treatment Basin (RTB), is equipped with a screenings grinder/washer/compactor (referred to as the grinder), located in the screenings collection room. The grinder receives the screenings and a large quantity of washwater which is conveyed from the perforated plate screens to the grinder via the shaftless screw conveyor.

The following are recommended improvements or alternatives to address the issues the Oakwood screenings system:

- Maintain washwater pressure at approximately 110 psi at the screens. Modify conveyor to add three drain sections (drain boxes)
- Continue to utilize existing grinder with modified discharge tube (as presently configured)

The system evaluation and alternatives analysis performed to arrive at these recommendations was focused on evaluating the existing screenings handling system components to identify feasible alternatives which address the goals of the task:

- Goal 1: Reduce amount of water flowing into grinder or dumpster when screenings grinder is off-line
- Goal 2: Address problems with grinder/washer/compactor (grinder) discharge tube clogging between events to improve reliability and reduce the time that the grinder is off-line during events

The evaluation was focused on meeting these two goals while being directed by the project guiding principles. In particular the following: reducing operation and/or maintenance required, providing

equipment which is accessible and easy to maintain, equipment selection to accommodate intermittent use, and maintain operation of Oakwood throughout the construction phase.

1.0 Introduction and Purpose

The screen facility at the Oakwood RTB is equipped with a screenings grinder/washer/compactor (referred to as the grinder), located in the screenings collection room. The screenings grinder receives the screenings and a large quantity of washwater which is conveyed from the perforated plate screens to the grinder via the shaftless screw conveyor. The screenings grinder had an inclined discharge tube to provide retention time and dewatering of the ground, washed screenings, as originally configured. The discharge tube was prone to clogging when the solids would dry and harden between storm events, preventing the equipment from working properly in subsequent storm events.

The screenings grinder can be manually repositioned away from the conveyor discharge chute by sliding it on the trolley and rail system, when not in use. When the grinder is moved to its off-line position, the screenings and washwater discharge freely to the dumpster below via a portable vertical chute section. The shaftless screw conveyor is designed with a tight seal between the conveyor spiral and liner, and no means of draining the water other than at the low point which does not receive much drainage. Therefore, the water is conveyed to the outlet and causes a significant amount of water to fall into the dumpster and floor on the lower level of the screenings collection room if grinder in off-line position.

The goals of this task are focused on addressing the two main operational challenges described above:

- Goal 1: Reduce amount of water flowing into grinder or dumpster when screenings grinder is off-line
- Goal 2: Address problems with grinder/washer/compactor (grinder) discharge tube clogging between events to improve reliability and reduce the time that the grinder is off-line during events

The following evaluations and investigations were performed during the study phase in an effort to address the goals above (in order of process flow):

- Evaluate potential to reduce the amount of washwater used at each screen (linked to Goal 1)
- Evaluate modifications to screw conveyor to reduce the amount of water conveyed to grinder (Goal 1)
- Evaluate existing grinder operation w/ modified, horizontal discharge tube (Goal 2)
- Investigate potential alternative washer/compactor equipment (Goal 2)

- Washer/compactor performance goals – no free water; more reliable; less maintenance

The remainder of this tech memo is organized as follows:

- Section 2 describes the Oakwood screenings handling system in greater detail.
- Section 3 provides information on evaluations performed to understand present operations and address the goals above.
- Sections 4 and 5 present the alternatives developed and evaluation of those alternatives to meet the goals of this task.
- The life cycle cost analysis (LCCA) is presented in Section 6 for alternatives that are deemed technically feasible and anticipated to address the goals and where there is some anticipated cost difference that can be quantified given specific assumptions about future operations.
- Finally, the recommendations for which alternative(s) should move forward into detailed design are summarized in Section 7.

2.0 Existing Oakwood Screenings Handling System Description

The screening removal and handling system at Oakwood CSO RTB, consists of six, 6-mm perforated plate screens, the shaftless screw conveyor, the grinder, and screenings dumpster. The general system description as summarized in the Oakwood Operations & Maintenance (O & M) Overview Manual follows. During storm pump operations, all six of the perforated plate screens are running and rotating at their maximum speed. Stormwater flows pass through the screening plates, into the Screen Outlet Chamber. Screened material collected by the screens is washed off using a combination of high-pressure spray water and a beater brush. The screenings and washwater discharge from the screen into a shaftless screw conveyor. The screw conveyor carries the screenings to the grinder which grinds the screenings to a smaller size and then washes and dewateres the screenings prior to discharging through a chute into a dumpster. In certain circumstance, such as when the grinder is out of service, the screenings can be discharged directly from the screw conveyor into a portable vertical chute and into the awaiting dumpster. These process elements are shown in **Figures 2-1** and **2-2**, provided for reference regarding the screen facility layout and general configuration.

Figure 2-1

Excerpt of Screen Facility Record Drawing - Plan

Figure 2-2

Excerpt of Screenings Collection Room Record Drawing - Section

2.1 Screen Washwater

The screens are cleaned as they rotate during operation by a motorized polypropylene bristle brush. After passing the brush, the screen plates are cleaned by a bi-directional spray wash constructed of stainless steel with brass nozzles. There are two spray bars with a total of 34 nozzles which clean the perforated plates of each screen. The design washwater pressure of 100 psi at the screen, is supplied by the secondary water high-pressure piping and duplex booster pump system located in the screen facility mechanical room. The maximum secondary water flow rate to each screen washwater system is designed to be 22 gpm. There is a 4-inch secondary water pipe that is routed below the conveyor and provides water to the washwater supply piping at each screen. Photographs of the booster pump system and the typical washwater supply piping are provided in **Figures 2-3** and **2-4**.

The pressure of the booster pump discharge to the high-pressure water system is controlled by a Pressure Reducing Valve (PRV) with a pressure setting range of 30 to 300 psi, which is set by positioning the pressure adjusting screw. The inlet pressure to each perforated plate screen spray bar can be fine-tuned by adjusting a “circuit setter” valve, also referred to by GLWA operators as a “dial” valve at the base of the washwater supply piping to each screen. There is a pressure gauge located on the washwater piping immediately upstream of the spray bars which indicates the water pressure provided to spray nozzles for cleaning each screen.

Figure 2-3
Oakwood Screen Facility Booster Pump System

Figure 2-4
Typical Screen Washwater Piping

2.2 Screw Conveyor

Two shaftless double spiral type screw conveyors work in unison (one pull and one push end to end in a common trough) to collect screenings falling off the perforated screens when in operation. The conveyor is located on the north side of the screens under the screen discharge chutes. The conveyor move the discharged screenings from the screens into the grinder or into the alternate chute bypassing the grinder.

The conveyor was specified to convey 250 cubic feet/hour of screenings material and washwater with 30% of the trough full, but according to the shop drawing can convey up to 312 cubic feet/hour with the trough 30% full. The troughs are U-troughs with integral flanges made of 316L stainless steel. There is a separate 6-inch flanged drainage outlet at the low end connected to a

drainpipe. See **Figure 2-5** for an overview photo of the conveyor. Screenings and washwater are discharged from the conveyor directly into the screenings washer hopper as described above.

The wear liner for the shaftless screw conveyor is made from ultra-high molecular weight polyethylene (UHMW-PE) and is replaceable. The liner is 12 mm thick, formed of two bonded layers, each of a different color (red and yellow), to provide a visible indication of when the liner is nearing the end of its useful life (replace when yellow inner liner is showing). The liner extends the full length of the trough, covering the entire semicircular bottom portion of the trough. The wear liner is inserted into the trough in 4-foot sections to provide ease of replacement. The liner is fastened to the trough using Type 316L stainless steel retaining clips welded to the trough.

Figure 2-5
Screw Conveyor

2.3 Screenings Grinder

The grinder is a self-contained, hopper fed system used to grind, wash, compact and dewater screenings that have been captured by the six Perforated Plate Screens during operation. The existing equipment is the JWC Washer Monster, Model SWM4018.

Once fed into the hopper the screenings are pulled into and through a grinder to reduce the size of the screenings. The ground solids are then passed through the auger, where water spray nozzles wash and separate the soft organics from the undesirable solids. The solids are compacted, dewatered and finally discharged as a cake from the discharge tube into dumpster below. The screenings grinder is designed to process up to 150 cubic feet/hour of wet screenings.

The grinder is made up of the inlet hopper, grinders, tank, trough, auger, and transport segment casing (discharge tube). The electric motors for the grinder and auger are explosion proof (Class I, Division 2, Group D) design, operating on 460 Volt, 3 Phase, 60 Hz power, requiring 10 HP for the grinder and 3 HP for the auger.

The inlet hopper is constructed from Type 316L Stainless Steel. The hopper has built in supports for the spray wash system. The inlet hopper is positioned under the screw conveyor to allow screenings to fall into the inlet hopper and a neoprene skirt is provided on the discharge of the conveyor to help prevent spilling out onto the floor.

A spray wash system provides wash water to clean the walls of the hopper. Explosion proof solenoid valves are used to control the spray wash water supply. A manual isolation ball valve is located on the wash water supply line to shut off or regulate the flow of wash water to the spray wash system. A bypass pipe is routed around the solenoid valve, with a manual ball valve to allow manual water flow to the spray wash system if the solenoid fails to open. Presently the manual isolation ball valve on the washwater supply line is closed. The water that is conveyed to the grinder from the screens is sufficient to keep screenings moving through the hopper and passively washing the screenings as it passes through the auger section to the drain.

The tank (auger/washer enclosure) has a 4-inch NPT drain with a 4-inch flush port. The tank is designed to allow it to be lifted from the system by the bridge crane and/or by forklift or similar devices. The tank has an inspection cover for access to the auger. The trough is a replaceable, Type 316L stainless steel assembly. The perforations in the trough are 0.25-in (6 mm). These perforations allow the screenings to dewater and separate liquids and soft organics from the solids as the screenings are washed and conveyed.

The auger spiral is made of a high wear-resistant, alloy steel. The outer edge of the upper portion of the spiral has a replaceable brush/wiper that cleans the perforations and protects the screen trough from excessive wear.

As of the spring of 2022 the grinder discharge tube was reconfigured to eliminate the 45-degree elbow/bend at the auger outlet and is oriented horizontally, as shown in **Figure 2-6**. This modification was fabricated to eliminate or reduce clogging of the discharge tube between events. Prior to 2022, the grinder was in the off-line position for an unknown duration but is assumed to be several years as operators could not recall how many years ago it was taken offline. The grinder is also assumed to have very few operating hours, relative to the age of Oakwood. The evaluation of grinder operation in this configuration is discussed in Section 3 and Section 5.

Figure 2-6
Grinder Configuration as of 11/27/22

3.0 System Evaluation

The Design Team performed five separate ride-along site visits during storm pumping events between late October 2022 and January 2023. Observations and data were collected during these visits to improve understanding of the screenings handling system operation and gain information from the operations staff at the facility, as summarized in this section for each of component of the screenings collection system. These site visits were also valuable to gain insights for the evaluation of alternatives as described in Section 5.

3.1 System Operation - Runtime

Three years of operating data was also acquired from the Ovation system, covering a period from September 2019 through October 2022. The screw conveyor running/not running data was used as an indication for when the storm pumps and screen facility were in operation. Analysis of this data showed that there were 112 operating events for the Oakwood Screen Facility or about 35 events per year on average. Event durations vary based on duration and intensity of the rainfall/snow melt that triggers the event, but often consist of periods during the storm event when operation cycles (starts/stops) as the storm wet well is drawn down and then fills. Since this analysis was focused on the screen facility operation, the storm events were not distinguished between those that resulted in discharge to the river and those that were storage only. The end of one event and start of another was characterized by at least 24 hours between shutdown and the next startup of the screw conveyor. Based on the total conveyor runtime of 1365 hours (about 57 days total) during the period of 3.2 years analyzed and the number of events identified, the overall average operating

time per event was approximately 12 hours. Utilizing the run time of the conveyor in this analysis was an overestimation of the storm pump and perforated plate screen operating time because it includes approximately 10 times (approximately 48 hours runtime) per year that the conveyor is running while the chutes from the screens and conveyor are being cleaned between storm events. However, it is a good approximation of the conveyor operating time and grinder operating time. This information will be utilized in the Alternatives Analysis and Life Cycle Cost Analysis provided in Sections 5 and 6.

3.2 Screen Washwater Pressure and Estimated Volume

The Design Team observed the screen washwater pressure as indicated by the pressure gauge located at each screen during several ride along events. The operating pressure at the screen is typically maintained close to 110 psi by the operators. They make adjustments to the pressure at each screen periodically by adjusting the dial valve at the bottom of the washwater feed piping at each screen. Screen #4 is operating at a slightly lower pressure due to the conditions of service for the replacement solenoid valve located at that screen. The operators indicated that they keep the pressure at screen #4 to 100 psi or less. The pressure observed on that screen was about 80 psi for three events (10/31/22, 11/27/22, 12/15/22), and about 100 psi for two events (12/30/22 and 1/19/23). The observed pressure at the other screens during all events ranged from 108-112 psi, except for Screen #1 which is at 120 psi. Screen #1 is likely experiencing a higher pressure because it is the first screen downstream of the booster pumps.

The perforated plate screen manufacturer, Andritz, provided information regarding the washwater flow rates predicted for each nozzle on the spray bars based on the nozzle geometry (orifice diameter and spray angle) and washwater pressure. As indicated in Section 2, there are 34 nozzles per perforated plate screen. **Table 3-1** provides a summary of the estimated washwater volume per screen with the existing nozzles, which are 0.05-in orifice diameter with 50-degree spray angle, at various pressures from 70 psi to 110 psi.

Table 3-1 Screen Washwater – Estimated Flow Rate per Screen at various Washwater Pressures

Washwater Pressure	70 psi	80 psi (Screen #4)	100 psi (design pressure)	110 psi (present operation)
Existing Nozzles (0.05 in)	18 gpm	19.4 gpm	21.4 gpm	22.3 gpm

3.2 Screen Field Observations

During several of the ride-along site visits observations were made during and after storm pumping and perforated plate screen operation. The purpose of these observations were to:

- Characterize the type and amount of screenings collected by the screens during operation
- Investigate the effectiveness of the screen cleaning mechanisms and washwater at cleaning the screen field during and at the end of storm pumping/screen operation

Observations of screenings on the front of screens indicates a fair amount of leaves and debris consisting mostly of small food wrappers, a few tissues/rags, a few identifiable sanitary trash items which are removed from the storm flow and carried up by the perforated plate screens. No large objects and not an overwhelming amount of leaves, were observed. Grit and fine particles were also carried up by the screens in between perforations. **Figure 3-1** provides a photograph as an example of the screenings collection observed during the ride-alongs.

During all the storm events during the study phase only one storm pump was operating at a time. Operators were also asked for their recollection and description of the typical screenings collected and they also indicated some small grit and dirt, small debris and leaves. They noted no large objects, but do see a lot of leaves, at times, presumably during a large rain event in fall.

Figure 3-1

Screen #2 while Storm pump #8 (ST-8) running (largest amount of screenings observed)

The Design Team attempted to assess the effectiveness of the screen washwater and brush at cleaning the screens through observations made while the screens were in operation and based on how clean the screens were after storm pumping stopped and the screens were shutdown. For the events where observations were made on all the screens and Screen #4 had washwater pressure at 80 psi, there were no differences noted between the cleaning of the other screens and Screen #4, when observing the front of the screen after the final cleaning cycle. Based on the limited debris on the screens during operation it could be assumed that the screens are being relatively well cleaned during each rotation, however, this may not account for passive cleaning taking place when the screen field is lowered down into the process flow on the downstream side of the screen. Therefore,

further evaluation is required to assess if the lower washwater pressure is cleaning the screen as effectively as the higher pressure washwater before reintroduced into the process flow. This assessment was performed during additional ride along events in February-March 2023 and is summarized in Section 5.1.

After the storm pumps stop running, the screens will run for an additional 5 minutes if they are in remote/automatic mode. If they are running in remote/manual then the operator will stop each screen manually from the control room but should still be allowing for some run-time after the pumps stop for the screens to see at least one full rotation or more for cleaning. While Screen #4 was observed during operation with 80 psi washwater pressure during three events, there was only one event (12/15/22) where it was observed after operation stopped. During this event, the screen field was sufficiently cleaned similar to other screens after operation stopped and is shown in **Figure 3-2**. The cleaning was also observed on 12/30/22 and 1/19/23, but the washwater pressure on Screen #4 was adjusted to approximately 100 psi during these events. Screen field cleaning was confirmed to be effective at that pressure as observed, however the uncertainty regarding passive cleaning by the process flow on the downstream side of the screen requires further evaluation.

Figure 3-2
Clean Screen #4 after Operation Stopped on 12/15/22

3.3 Conveyor Operation

Observations of the screw conveyor operation during field visits included opening the hinged covers, after Great Lakes Water Authority (GLWA) operators removed the bolts from the cover plates, over the drain section at the low end of the conveyor and over the section near the discharge end, between Screens #4 and #6.

The observations of the drain section included:

- Accumulated debris – likely due to brush wear and minimal brush contact due to flights being higher close to drive (alignment not allowing brush contact with perforated plate)
- During operation little/no water flowing back to low point drain section (**Figure 3-3**)

Figure 3-3
Inside conveyor at drain section during operation

Observation of the conveyor section between Screens #4 and #6 showed the following:

- Confirmed significant amount of water conveyed to discharge end of conveyor
- Water and screenings moved forward well and not wrapping or accumulating on the spiral (**Figure 3-4**)
- At this location of the conveyor, it is full to nearly the top of the liner during operation
- Spiral and liner are in good condition. Liner shows some wear from the spiral but is not showing indication of wearing through the top layer.

Figure 3-4
Inside operating conveyor between Screens #4 and #6 during wet weather event

3.4 Screenings Grinder Operation

The grinder was offline for many years due to screenings hardening in the discharge tube between storm pumping events resulting in the grinder being unable to push the plug of hardened, compacted, dried screenings out during the next event. Under the CS-299 CSO Facilities Needs Assessment project, technical representatives from JWC, the equipment manufacturer, assessed the conditions of the grinder/washer/compactor in October 2020. They found that the unit was operational, and was in very good condition since it had low runtime. To reduce the possibility of clogging they suggested changing the discharge tube elbow to 11 degrees to create a reduced inclination angle. In the CS-299 report a modification of the discharge tube to horizontal was recommended. The JWC field report also indicated that the water supplied to the hopper above the grinder could be turned off. With the amount of water that is coming in from the conveyor, the additional water to prevent screenings from accumulating on the sides of the hopper was deemed unnecessary.

In the spring of 2022, GLWA modified the discharge tube to a horizontal configuration as described in Section 2. GLWA also turned off the water feed to both the hopper and the washer/auger section of the grinder so that just the water from the conveyor was passing through the grinder to the drain.

Based on operator interviews at the start of this project, the grinder was identified to be working well and the horizontal discharge tube configuration is providing sufficient dewatering and is not clogging between events. Sufficient dewatering in this situation is defined by absence of any free water flowing or dripping from the end of the discharge tube. When the modification was made to the horizontal discharge tube, the initial configuration had the outlet end/opening facing the side. This did cause a problem where dewatered screenings that dried and hardened at the end of the tube between events would push out of the tube and against the side of the discharge chute with enough force to move the grinder out of alignment with the conveyor discharge. The Design Team observed the grinder in operation during an event where this occurred (11/27/22). The end of the discharge tube was adjusted to open generally downward shortly after this event. See **Figure 3-5** for present grinder configuration.

Observations made after the discharge tube end was modified to generally downward show that:

- No free water is present (no water going into the dumpster below) when the water supply to the grinder is off (only processing the screening washwater from the conveyor)
- Screenings falling away in smaller clumps and there is no longer a problem with the grinder being pushed out of alignment

There has been limited time between events in the present configuration, however it appears that the grinder is working well and has been reliable in this configuration. Additional observations should be made in coming months if there is an opportunity with a longer idle time, greater than the 2 to 3 weeks between events observed after the modification.

Figure 3-5
Grinder Discharge Tube with Outlet Facing Down (present configuration)

3.5 Future Screenings Production Estimate

The Design Team calculated an estimate of the screenings produced from the existing 6 mm perforated plate screens based on design storm total treated volumes under current collection system conditions and future collection system conditions, after the proposed Oakwood District Intercommunity Relief Sewer (ODIRS) is completed. The screenings volume estimations in **Table 3-2** are based on the estimated screenings removal rate for 6 mm perforated plate screens of 1-3 ft³/MG as described in the GLWA Wastewater Master Plan Report TM-5a.

- The estimated screenings production under existing conditions are well within the storage capacity of the existing 10 cubic yard (CY) dumpster.
- The estimated screenings removed from the treated design storm volume at Oakwood for future collection system configuration would be up to 5.5 times greater than the current volume.
- The estimated screenings volume after compaction for the future 10-year, 24-hour storm event is about 5-17 CY.
- Depending on the storm event characteristics, the future screenings volume may fill one 10 CY dumpster. It is recommended that GLWA consider the staff needed as well as additional dumpster and dumpster moving equipment that may need to be on-site and available to reposition the dumpster(s) under the discharge chute during storm events. Alternatively, equip the facility with 20 CY dumpster and provide equipment on site to shift the dumpster position as needed during event to fill the dumpster across a greater percentage of the surface area and minimize screenings falling out of the dumpster.

Table 3-2 Estimated Screenings Production at OKW Before and After ODIRS Constructed Based on 1-3 cf/MG (for Raw-Wet Screenings)

Design Storm	Raw Wet Screenings Estimate			Compacted Screenings Estimate ²
	Total Treated Volume, MG ¹	Lower Limit, ft ³ (CY)	Upper Limit, ft ³ (CY)	Lower – Upper Limit, CY
10-year, 24-hour (design peak wet weather event)				
Current Collection System Configuration	80.5	80.5 (3)	242 (9)	1.2-3.6
Future Collection System Configuration	368	368 (14)	1,105 (41)	5.5-16.4
6-month, 24-hour (design average wet weather event)				
Current Collection System Configuration	16.5	16.5 (1)	49.5 (2)	0.4-0.8
Future Collection System Configuration	92	92 (3)	277 (10)	1.2-4

²Based on WWMP estimated screenings volume reduction of 60% through a washer/compactor.

4.0 Description of Alternatives

Alternatives were developed for each of the screenings handling system components to address the task goals of reducing the amount of water conveyed to the grinder and improving the reliability of the grinder operation by reducing or eliminating issues with screenings clogging the discharge tube between events. Discussion of advantages and disadvantages for the feasible alternatives is provided in Section 5.

The alternatives for reducing the amount of water conveyed to the screenings grinder are limited to modifications that could be made to the existing screens and conveyor. This equipment is overall in good working condition and not planned for replacement.

4.1 Screen Washwater Reduction

The perforated plate screens use high-pressure washwater applied through a series of spray nozzles, along with a rotating brush, to clean the screen field as it rotates during operation and for a given duration after storm pumping stops. As shown in **Table 3-1**, the present configuration and operation of the perforated plate screens utilizes approximately 22.3 gpm per screen.

The Design Team contacted the screen manufacturer, Andritz, to inquire whether there were any advancements in the design of the screens or cleaning mechanisms, since the time the Oakwood screens were manufactured, that would allow for a reduction in the amount of washwater required for cleaning. They indicated that the design has not changed. The options that they provided for reducing the amount of water applied to the screens were to:

- Reduce the pressure of the water feed to the spray nozzles, which would reduce the volume of water that can pass through the fixed nozzle orifice
- Replace the nozzles with ones with a smaller orifice size, which would also reduce the volume of water that can pass through the nozzle orifice, but at the original water pressure.

With either option Andritz recommended a trial period for evaluating if the screens are being sufficiently cleaned after modification.

For example, this would mean replacing the nozzles on one screen first to evaluate how well it cleaned and then completing the replacement on the other screens. The pressure reduction could be evaluated by adjusting the valve at one screen or several screens for evaluation before making the lower pressure the standard operation for the facility.

Andritz provided a data sheet for the spray nozzles used in the perforated plate screens which showed the expected flow rate per nozzle based on size and pressure. Some interpolation was required to estimate the flow rates at the desired pressures, so the flow rates are approximate. Estimated flow rates for the total flow at each screen using the existing nozzles are shown in **Table 3-1**. If the pressure is reduced to 80 psi the washwater utilized at one screen would be reduced from 22.3 gpm (at 110 psi) to 19.4 gpm, saving about 3 gpm per screen or 15% reduction in

washwater. If the nozzles were replaced with nozzles of the next smaller orifice size, and the feed pressure was reduced to the original design pressure of 100 psi, the water use per screen would be about 16 gpm.

Evaluation of the effect of potential changes in washwater flow rate on the booster pump system is provided in Section 5.

4.2 Screw Conveyor Modification

Alternatives for reducing the amount of water conveyed to the grinder by modifying the screw conveyor were investigated by the Design Team. Based on discussion with the screw conveyor manufacturer, Spirac, and Design Team technical staff concerning other recent perforated plate screen and screw conveyor installations, the only alternative identified was to install additional drainage sections along the length of the conveyor. As noted in Section 3, there is little to no water draining back past the spiral to the existing drain section at the low end (upstream of all the screens) of the conveyor. It is now more common for the conveyor to be configured with a drain box, similar to the existing one, at a location beyond the screens where more water is present in the conveyed material.

Spirac has recommended adding three drain boxes to the existing conveyor as shown in **Figure 4-1**. Spirac would provide the parts for the drain boxes including the 316 SS perforated plate with 5mm holes for the trough, drainage collection box and 6-inch flanged drain outlet, and brushes to attach to the spiral at each drain section to clean the perforations as the screw rotates. New 6-inch PVC drainpipes would be routed to new openings to the screen outlet channel below the floor to discharge the drained water. These are shown conceptually from the drain boxes screen channels in **Figure 4-1**.

The installation would be performed by a local contractor with certification to weld and passivate 316 stainless steel. A manufacturer's representative could also be present in the field to provide guidance and instruction at the start of the retrofit process or for the entire duration. The drain box installation could be performed during dry weather and completed within approximately three days for all three drain boxes.

Figure 4-1
Conveyor Additional Drain Sections – Conceptual Layout (Drawing background: Spirac Shop Drawing)

The description of the drain box installation process from Spirac is:

- Empty the conveyor of all screenings
- Disconnect power supply to the conveyor
- Lift the spiral
- Cut the section of the conveyor and liner out for installation of the drain box—same dimension as the drain box
- Weld the brush clips on the existing spiral and attach the brush where the drain box is to be installed
- Using a continuous weld, weld the drain box into the existing conveyor
- Drain box will come complete with perforated plate drain section
- Attach the drainpipes to the drain boxes

4.3 Screenings Grinder Alternatives

The grinder alternatives were developed to address the goal of improving the screenings grinder/washer/compactor reliability by reducing the likelihood of the discharge tube to clog and provide sufficient dewatering such that no free water is flowing into the dumpster. The two alternatives identified are:

- Continue using the existing grinder with the modified, horizontal discharge tube
- Replace the grinder with a new screenings washer compactor

Based on observation of five events and historical information from discussion with operators, as described in Section 3, there is no large debris or items that would jam the auger being removed. Therefore, the observations suggest that the grinding function is not needed. This provides the opportunity to reduce maintenance of both a grinder and auger motor and the grinder equipment

by removing that function from the alternative equipment being considered. The alternative equipment performs washing and compaction of screenings only based on this “no large debris” finding.

Two manufacturers of screenings washer/compactors were identified who could offer equipment with the capacity to process a screenings volume equal or greater than the 312 cubic feet/hour capacity of the conveyor. These were Kusters-Zima and Huber. This equipment was considered as an alternative to the existing grinder to provide reliable operation based on increased capacity to accommodate additional screenings load (matching the conveyor capacity), increased auger power to push screenings through discharge tube, experience of screenings-handling-focused engineers of the Design Team with these manufacturers coupled with their reliability compared to JWC, and the removal of the grinder function to simplify the dewatering equipment operation and maintenance.

The existing grinder capacity is only 150 cubic feet/hour. Due to the larger capacity both manufacturers have a larger tank and auger section and a higher power motor on the auger than the existing equipment. Overview schematics and highlighted features of the alternative washer/compactors are shown in **Figure 4-2**. The equipment configuration description of the existing grinder compared to the alternative washer/compactors is provided in **Table 4-1**.

The evaluation of the alternative washer/compactors is described in the next section and included consideration of fit within the existing structure and ability to meet the task goals and guiding principles. The discharge tube configuration would be customized by coordinating with each candidate manufacturer to minimize the angle of the discharge bend and the tube length. Preliminary coordination was done to evaluate the capability and suitability of the equipment for this project as discussed further in Section 5.

Figure 4-2
Alternate Washer/Compactor Equipment Conceptual Overview – Kusters-Zima and Huber

Table 4-1 Description of Equipment Configuration for Screenings Washer Alternatives

Feature	Existing Grinder	Alternate Washer/Compactors
Number of Units	1	1
Type	Wash press w/ integral grinder	Wash press
Capacity	150 cu ft/hr	312 cu ft/hr (approx.)
Maximum Motor Size	Grinder: 10 HP Wash Press (auger): 3 HP	Wash press (auger): maximum 15 HP
Discharge Tube configuration	Horizontal w/ length of 5 ft	22.5-degree upward bend w/ maximum length of 3 ft

4.4 Alternatives Evaluation Criteria

Several criteria are used to evaluate the alternatives described above. These criteria and the associated project guiding principles include:

- Fit within the existing structure

- Meet the needs of the facility and goals of the improvements required, without adverse impact to adjacent equipment or systems
- Reduce operation and/or maintenance required
- Provide equipment which is accessible and easy to maintain
- Equipment selection to accommodate intermittent use
- Maintain operation of OKW throughout construction phase
- Cost

Any alternatives that do not meet certain criteria may be eliminated from further consideration. For example, an alternative may be eliminated if deemed not technically feasible based on fit within the existing structure or causes a potential detrimental effect on adjacent equipment or systems. Alternatives that pass the technical feasibility test are evaluated based on the remaining criteria which may be more value-based criteria and considered by examining the pros and cons of each alternative.

5.0 Alternatives Analysis

This section provides evaluation of the alternatives relative to the criteria listed above. The technical feasibility of alternatives to fit within the existing structure and potential effect on adjacent systems are discussed. These evaluations can lead to removal of alternatives from further evaluation. The alternatives that are deemed technically feasible are further evaluated for their advantages and disadvantages relative to the other criteria such as maintenance and operational reliability. The life cycle costs analysis (LCCA) in Section 6 is only prepared for the final, remaining or leading alternatives where cost differences are beneficial in supporting a recommended alternative in Section 7.

5.1 Screen Washwater Reduction

As described in Section 2, the high-pressure water is supplied for cleaning the perforated plate screens using a booster pump system located in the Screen Facility Mechanical Room. The Design Team reviewed the pump curves, as provided by the pump manufacturer, to evaluate the affect that reducing the flow rate of water to the perforated plate screens could have on the booster pump operation. It was assumed that all six screens are available and operating with the given amount of washwater supplied for this evaluation. The pump curve is shown in **Figure 5-1**, with the approximate operating point for the total washwater feed rates under different operation conditions are indicated. **Table 5-1** summarizes these alternative operating conditions, total flow rates, and the Design Team's conclusions regarding whether these conditions may have an adverse effect on the booster pumps. Each set of conditions is shown with and without approximately 20 gpm of washwater, total for both the hopper and auger, being used at the grinder. The washwater

TM-4 Oakwood Screw Conveyor & Grinder System Modifications

June 1, 2023

Page 22

to the grinder is presently turned off and it is unknown if that condition will persist into the future or if future conditions will include use of washwater for the grinder hopper or screenings washing.

Table 5-1: High-Pressure Washwater Feed Rate Conditions

Conditions	Total Estimated Flow (gpm)	Booster Pump Operating Range Acceptable
Present– 5 screens at 110 psi and one screen at 100 psi, zero flow to grinder	131	Yes
Alt 1 – 6 screens at 80 psi & 20 gpm to grinder	134	Yes
Alt 1b – 6 screens at 80 psi & zero flow to grinder	114	Yes, but this is in the flatter part of the curve and approaching the Allowable Operating Region (AOR) or min stable flow in Figure 5-1, and pump operation should be monitored [based on all 6 screens in operation]
Alt 2 – 6 screens at 100 psi, with smaller orifice nozzles installed, & 20 gpm to grinder	116	Yes, but this is in the flatter part of the curve and approaching the Allowable Operating Region (AOR) or min stable flow in Figure 5-1, and pump operation should be monitored [based on all 6 screens in operation]
Alt 2b – 6 screens at 100 psi, with smaller orifice nozzles installed, & zero flow to grinder	96	No, this is too close to the AOR left limit and well into the flat part of the curve
Alt 3 – 6 screens at 70 psi (existing nozzles), & 20 gpm to grinder (unknown screen cleaning performance, typical)	128	Yes
Alt 3b – 6 screens at 70 psi (existing nozzles), & zero flow to grinder	108	No, this is too close to the AOR left limit and well into the flat part of the curve

Figure 5-1
Tyco Furnished Model KS2009 Booster Pump Curve & Approximate Operating Points for Estimated High-Pressure Water Feed Rates

Based on review of the booster pump performance curve and potential flow rates with each of the perforated plate screen washwater alternatives, the Design Team removed Alternatives 2 and 3 from further consideration. If the washwater to the grinder is not utilized and the screen washwater feed rates are reduced as in these two alternatives, then there is a risk that the booster pumps will be operating in a flow range that would cause the pump to operate outside or very close to the AOR left limit resulting in reduced service life, increased maintenance and lower efficiency.

The reduction in screen washwater by reducing the pressure at the screens to 80 psi (Alternative 1) was deemed technically feasible to move forward for further consideration and evaluation. Evaluation of the screen cleaning performance at the reduced pressure was completed during three additional ride along visits on 2/22/23, 2/27/23, and 3/4/23. There is also the option to reduce the operating pressure to the design pressure of 100 psi and not operate at 110 psi at the screens. This is not discussed in detail but would reduce the water usage by about 1 gpm per screen (~5% reduction).

The pros and cons of the alternative to reduce the washwater pressure to 80 psi compared to leaving the washwater pressure as-is (or reducing to 100 psi) are presented in **Table 5-2**.

Table 5-2 Advantages and Disadvantages of Reducing the Water to Each Screen

Alternatives	Advantages	Disadvantages
Reduce washwater pressure to 80 psi at the screens [based on all six screens in operation]	▪ Slight reduction in water applied per screen ▪ Cost savings for reduced water usage ▪ Approximately 15% less water flowing into dumpster if grinder offline (without conveyor modifications)	▪ Decrease in screen cleaning performance (based on observation of screen field between spray nozzles prior to screen field return into channel)
No change to screen washwater settings (maintain same flow and pressure)	▪ Screens continue to be cleaned as well as present conditions ▪ Water appears to be accommodated by the modified grinder (without conveyor modifications)	▪ Paying for water that may not be needed

The Design Team met with GLWA on 2/13/2023 to discuss these alternatives. GLWA operators were receptive to this concept and offered to adjust the washwater pressure down to 80 psi at each of the screens for evaluation. The Design Team suggested that the pressure reduction be on one screen only and could be compared to other screens. This evaluation was completed with GLWA operators reducing the washwater pressure to 80 psi on one screen, close to the discharge pipe of the operating storm pump, and maintaining the pressure at 110 psi on the next closest screen. GLWA opened the access door located below the cleaning brush and spray nozzles on both screens to allow observation of screenings that were not washed off before the screen pass into the screenings channel. The Design Team observed the screen cleaning in-person and captured photos and video clips for comparison between the screen cleaning with 80 psi and the screen cleaning

with 110 psi washwater. The following observations were made regarding the cleaning of the perforated plate screen field:

- Observations are challenging when the screens are in operation due to the spray and mist from the washwater nozzles and limited range of about two sections of the screen field visible at a time as it rotates through the access door area, however the screen field could be seen well enough to observe differences in cleaning performance.
- Both screens appeared to be fairly clean overall and did not have any significant sized or amounts of screenings carrying over and going past the brush and washwater.
- Detailed review of the video and photos taken during the evaluation did show that the screen with reduced washwater pressure would at times (every few screen segments) have several small bits of debris, about the size of a nickel or dime or smaller and natural in appearance (no trash items), that stuck to the screen and were not washed off. See **Figure 5-2** for an example or what was observed every approximately five screen segments.
- The screen with typical washwater pressure, 110 psi, also had some small bits of debris that stuck to the screen but these were smaller and less frequent/numerous. See **Figure 5-3** for an example of what was observed every approximately 5-10 screen segments.

Figure 5-2 – Example of Screen Cleaning with 80 psi Washwater Pressure

Figure 5-3 – Example of Screen Cleaning with 110 psi Washwater Pressure

Based on these observations, the Design Team concluded that there was a sufficient increase (double to triple the quantity) in the limited amount of screenings carryover with reduced washwater pressure to 80 psi that this change should not be recommended given the permit compliance considerations with screenings carryover.

While the evaluation was being performed, the potential cost savings of reducing the pressure and reducing the volume of water applied to each screen was calculated. The potential cost savings of applying less water to each screen is about \$6,000/year, assuming change from 110 psi to 80 psi washwater pressure, with associated reduction of 17 gpm total for six operating screens. This is based on the estimated annual operating hours as described in Section 3, which included 36 events with an average runtime of 12 hours per event (or the equivalent of 18 full days per year) and a water rate of \$44.92/1000 cf (Mcf), \$6.01 per 1,000 gallons of water (kgal) plus sewer rate of \$55.40/Mcf, \$7.41/kgal, from the Detroit Water and Sewerage Department (DWSD) 2023 rates document provided by GLWA. The sum of these rates, \$13.41 is applied to the estimated volume of water saved to get the cost savings value. The estimated cost savings for reducing the water pressure is small compared to other operating costs at the facility coupled with concerns with additional screenings carryover supports the recommendation to maintain the present washwater pressure.

5.2 Screw Conveyor Modification

The only feasible alternative for reducing the amount of water reaching the end of the shaftless screw conveyor was to add drain boxes supplied by the conveyor manufacturer. These drain boxes

would consist of a 316L stainless steel perforated plate and box with 6-inch drain outlet to replace a section of the conveyor trough in three places. A brush is added to the spiral flights in contact with the drain section to keep the perforations clear of debris.

The drain boxes are about 1-foot long and will fit under the conveyor trough as shown in **Figure 4-1**. Routing of the drainpipe to the screen outlet channel would need to be determined to avoid the conveyor support structure and existing secondary high-pressure water piping, but conceptually this is feasible in the area near the proposed drain boxes.

The pros and cons of this alternative, compared to not installing the drain boxes are discussed in **Table 5-3**

Table 5-3 Advantages and Disadvantages of Adding Drainage Sections to the Conveyor

Alternatives	Advantages	Disadvantages
Modify conveyor to add 3 drain sections (drain boxes)	- Should have significant reduction in water conveyed to grinder/washer/compactor - Less water flowing into dumpster/screenings collection area when grinder/washer/compactor offline.	- Potential for clogging and cleaning needed for drain sections (potential maintenance needed between events) - No excess water for screenings washer thus need to use more secondary water, but has advantage at washing system pressure distributed via the header - Replace brushes on spiral as wear occurs (estimated every 5+ years)
No change to conveyor	- No additional cost or maintenance required. - Existing grinder continues to utilize the excess water as washwater	- Large amount of water conveyed to grinder and to dumpster/collection level if grinder off-line - Does not address the goal to reduce the water to the grinder - Passive flow of water through auger section not cleaning screenings as well as pressurized water through nozzles would

During the meeting on 2/13/23 with GLWA, they expressed interest to know what other customers with drain sections along the length of the shaftless screw conveyor experience regarding ability of the spiral brush to keep the drain section clear and how well the water drains through the drain boxes. The Design Team is working with the manufacturer, Spirac, to obtain references and follow-up on this aspect of the evaluation.

This alternative is not evaluated in the LCCA, because there is only one alternative, adding the drain boxes, which will address the task goal to significantly reduce the amount of water conveyed to the grinder. There may be additional maintenance required to periodically clean the drain sections and replace the brushes on the spiral, but no other alternatives were identified.

5.3 Screenings Grinder Alternatives

The two alternatives identified to improve the grinder reliability and address concerns with intermittent operation are to continue using the existing grinder with the modified discharge tube or purchase a new washer/grinder. As discussed in Section 4, it was determined that if the grinder is replaced, the grinder function would not be necessary based on the screenings composition observed during several events and based on historical information from operations staff.

To meet the criteria of fit within the facility and access for maintenance, the Design Team evaluated the equipment data sheets and dimensional drawings provided by the two equipment manufacturers contacted. Excerpts of these drawings are shown in **Figure 4-2**. Due to the larger capacity and larger motor than the existing equipment, the overall length is greater than the existing grinder. This results in insufficient clearance on the right side of the machine between the motor and guardrail to access the back of the machine or maintain the motor with the manufacturer's standard arrangement. The Design Team worked with the manufacturers' sales engineers to adjust the alignment for the washer/compactor below the conveyor and shorten the discharge tube, so the washer/compactor could move to the left and provide about 3 feet of clearance between the motor and the guardrail. The discharge tube was shortened so the end of the discharge tube can align with the opening in the screenings washer platform for discharge of the compacted screenings to the dumpster below. With these modifications the alternative washer/compactors can meet the evaluation criteria of fitting within the existing structure.

Screenings Washer Platform and Conveyor Drain Piping Structural Considerations

If another manufacturer is identified or if this alternative moves into detailed design and one of the manufacturers is unable to provide a short enough discharge tube to align with the existing opening, the Design Team also performed a structural evaluation of the feasibility to modify the screenings washer platform to expand the opening to the screenings collection area below and extend the footprint of the platform if needed as well.

The existing platform is a reinforced concrete structure supported on concrete beams. The existing platform could be expanded if needed with a maximum expansion of 8 feet. However, this expansion would limit access of the bridge crane to the lower level of the structure and is not preferred unless absolutely required.

The new screenings washer may require an increase in the chute opening. This chute opening poses no structural concerns if it avoids the existing structural beams below the slab.

For the conveyor drain piping, several 8-inch cores will need to be added. The contractor will be required to scan the existing slab with ground penetrating radar to locate rebar and where possible cores will be located to avoid rebar or where rebar cannot be avoided cores will be located to minimize cut rebar.

Alternate Washer/Compactor Accommodation of Intermittent Use

Coordination with the washer/compactor manufacturers also focused on modification and evaluation of the equipment to balance the needs of dewatering/compacting the screenings and reducing the potential for the discharge tube to clog between events. Both manufacturers are offering a minimum of 22.5-degree bend in the discharge tube and neither was willing to provide a lower angle or horizontal discharge tube. They want the bend so that there is some back pressure on the auger to provide dewatering and some compaction of the screenings. This is a lower degree bend than their standard 45-degree bend. The discharge tube beyond the bend widens in diameter from the bend to the outlet. The length and incline of this section provides further dewatering but the widening reduces screenings contact and sticking to the walls of the tube. The shorter length of the tube will also help reduce the screenings resistance to moving through the tube.

Despite the shorter, wider tube, relatively low angle bend, and the higher horsepower auger motor to help push screenings through the discharge tube and minimize potential for clogging between events, both manufacturers recommend a preventative maintenance activity at the end of event to loosen remaining screenings in discharge tube. The suggestions included possibly adding ice chips or water via a flushing port to move more screenings out of the discharge tube; or rake out debris from the reachable portion of tube. If the alternate screenings washer is selected, the design would include reconfiguring/replacing the vertical chute so that the outlet of the washer/compactor chute is accessible. The significantly shorter discharge tube would improve the feasibility to reach and loosen the screenings. However, this required action and the remaining potential for clogging between events does not meet the criteria of reducing maintenance required and accommodating intermittent use.

The pros and cons of the alternative for a new washer/compactor, compared to continuing to use the existing grinder in its modified configuration are discussed in **Table 5-4**.

Table 5-4 Advantages and Disadvantages of Washer/Compactor and Grinder Alternatives

Alternatives	Advantages	Disadvantages
Replace with new Washer/Compactor	- Only one motor (auger) to maintain and power. - Larger motor with more power to push screenings through auger and discharge tube - Shorter discharge tube (to accommodate longer compactor unit and meet existing floor opening) - Larger capacity (312 cu ft/h v. 150 cu ft/hr) to accommodate future conditions	- Larger size of equipment, may reduce clearance on motor side of unit - Both manufacturers have minimum elbow of 22.5 deg (will not do horizontal discharge) - Both mfrs recommend break up plug with rake or stick at end of event to reduce hardening and clogging for next event; or flushing, ice chips or wetting screenings in elbow - Replaces equipment that has limited operating hours
Continue to utilize existing JWC grinder compactor with modified discharge tube	- Lowest cost, near term—continues to utilize existing equipment with very low runtime hours - Familiar with the equipment - Small/compact unit, fits in existing space - Provides dewatering and discharge tube modification appears to have eliminated clogging issue - No free water discharged (with present operation—washwater turned off)	- Grinder section is additional point of future failure potential - Additional maintenance for grinder motor, gear box and cutters. - Conveyor outlet requires modification to prevent drips between neoprene and inlet hopper

GLWA expressed a preference to continue using the existing grinder with horizontal discharge tube over replacing the unit, during the meeting on 2/13/23. This preference is based on their present satisfaction with how the existing grinder is operating since the discharge tube horizontal configuration has been in place with a downward facing outlet. They also have concerns about the proposed bend in the alternative washer/compactors causing clogging and not allowing for intermittent operation without an increase in maintenance.

The LCCA presented for this alternative in the next section compares the costs to purchase, install, operate, and maintain a new washer/compactor compared to the existing grinder.

6.0 Life Cycle Cost Analysis

The Life Cycle Cost Analysis (LCCA) was prepared for the new washer/compactor equipment and compared to continuing to use the existing grinder for a 20-year period starting from the estimated end of project construction.

6.1 Approach

The LCCA provides comparative cost estimates intended to represent order-of-magnitude estimates for equipment capital and O & M costs. It is intended for planning purposes and comparing

alternatives, and does not serve as an opinion of probable construction cost (OPCC). The costs developed for this project phase are based on general requirements of each alternative. The alternatives that were not eliminated from further consideration based on technical feasibility to meet project goals and where there are two remaining viable alternatives, are included in the LCCA. As described above, for the screenings conveyor and grinder system modifications, this includes the comparison between replacing the grinder with a larger capacity screenings washer/compactor compared to keeping and maintaining the existing grinder. Escalation rates are applied to move present costs into the future to the time when the purchase, energy use, or maintenance will occur. Then a discount rate is applied to move those future costs back to the present and provide the net present value of each alternative. The individual escalation rates are discussed in the following sections. The discount rate applied is 4%.

6.2 Initial Purchase and Installation (include commissioning and startup)

Initial purchase costs are based on budgetary costs estimates for the washer/compactor. The costs include the washer/compactor, with quick connect power cables, and a trolley/cart for moving the unit from on-line to off-line position. The highest of the two budgetary cost estimates received were used in the analysis. To accommodate the larger equipment and provide access to the discharge tube, a modified vertical discharge chute was included in the initial purchase cost. This would be a section of the chute from below the screenings washer/compactor discharge tube to the opening in the floor.

Supporting component purchase costs were estimated as by approximate percentage of primary equipment cost. For the screenings washer/compactor these estimates included 10% for miscellaneous electrical and 10% for instrumentation and control.

Installation and commissioning were estimated as 30% of the equipment purchase, plus an estimated cost for the equipment manufacturer's field representative to oversee and confirm proper installation and startup. Two, 1-day trips were assumed for the LCCA.

Contractor costs, including general conditions, permits, insurance, bonds, overhead and profit, and 30% contingency were added to the purchase, installation, and commissioning costs as an overall percentage of 75%.

The total installation and commissioning costs were escalated from February 2023 to the approximate mid-point of construction, estimated to be May 2027, based on the project schedule at the time of the analysis. The escalation rate utilized is 6% annually.

6.3 Operation, Energy, and Maintenance

These costs applied to both the new screenings washer/compactor and the existing grinder. Operation costs were based on the usage of washwater in the inlet hopper and to wash the screenings as they move through the tank and auger section. The average water usage is 20 gpm. The operating duration for each year was estimated based on the screw conveyor operating hours as described in Section 3 and amounts to 36 events with an average runtime of 12 hours per event

(or the equivalent of 18 full days per year). The annual water use cost was calculated using a water rate of \$44.92/1000 cf (Mcf), \$6.01 per 1,000 gallons of water (kgal) plus sewer rate of \$55.40/Mcf, \$7.41/kgal, from the DWSD 2023 rates document provided by GLWA. The sum of these rates, \$13.41 is applied to the estimated volume of water. It was assumed that the existing grinder will also use 20 gpm in the future to move screenings through the inlet hopper and grinder and wash screenings in the tank and auger section, assuming the amount of water conveyed by the screw conveyor is significantly reduced. An annual escalation rate of 3.5% was applied to the water cost rate. Energy usage costs for both alternatives were based on the operating hours per year as described above and the nominal nameplate horsepower (HP) of each motor converted to kilowatts (kW). The washer/compactor only has one motor for operating the auger but one of the two manufacturers investigated has a 15 HP motor, and the other manufacturer uses a 7.5 HP motor for this function. This is higher than the 3 HP motor on the existing grinder auger. However, the existing grinder has a 10 HP motor on the grinder element, so the total HP used is 13. The energy escalation rate applied is 2.7% per year.

The amount of maintenance required for each alternative was estimated based on potential maintenance activities after each event, annual preventative maintenance, and estimated spare parts replacement at times during the life of the equipment.

The following maintenance cost assumptions were applied to the alternative with the new washer/compactor:

- Estimated 30 minutes would be required at the end of each event to clear the discharge tube or break up the plug so that it further reduces the potential for clogging at the next event.
- Annual preventative maintenance for inspection and lubrication was estimated as a total of 16 hours, based on two staff, 8 hours once per year performing inspection and lubrication of parts that do not require any disassembly of the unit.
- Estimated repairs and/or spare parts replacement, was applied at year ten of the equipment life and assumed to be 10% of the original purchase cost.

The following maintenance cost assumptions were applied to the alternative continuing to use the existing grinder:

- Estimated 15 minutes of maintenance to check the unit after each event and/or minor, periodic housekeeping around the unit.
- Annual preventative maintenance for inspection and lubrication was estimated as a total of 32 hours, based on two staff, 16 hours once per year performing inspection and lubrication of parts that do not require any disassembly of the unit.
- Based on the very low runtime hours on the existing grinder, it was assumed the existing equipment would not require a full replacement within the 20-year time period and

maintenance repairs/replacement would be similar to the alternative for a new washer/compactor.

- Estimated repairs and/or spare parts replacement, was applied at year ten of the equipment life and assumed to be 10% of the original purchase cost. An updated purchase cost was obtained from JWC to use in this estimate.

The following assumptions apply to both alternatives:

- An average labor rate of \$140/hour (including benefits) was utilized.
- Maintenance costs were escalated 3.5% from present (2023) to the year when performed

6.4 Decommissioning/Salvage

The salvage value was estimated as 10% of the original equipment purchase cost (before sales tax), and then escalated to the end of the 20-year analysis period using a 3.5 annual escalation rate (consistent with the maintenance escalation rate). Salvage value is shown as a negative value in the LCCA because it is an income as compared to the other values included in the analysis, which are costs.

The salvage value assumed for the existing grinder was based on a present (2023) budgetary cost estimate obtained from JWC for the same model as the existing grinder.

6.5 LCCA Results

Table 6-1 provides a summary of the LCCA for the screenings conveyor and grinder system improvements focused on comparison of the two alternatives for either replacing the grinder with a new washer/compactor (eliminating the grinding function) or continuing to use the existing grinder. All values in the table are rounded to the nearest \$5,000.

This analysis shows a significant difference in cost due to the purchase of new equipment for Alternative 1. The O&M costs for both alternatives are within the \$5,000 rounding for electricity and water use; and have a difference of \$35,000 based on additional maintenance needed for the existing grinder to maintain the grinder, gear box and motor, in addition to a slightly higher replacement parts cost estimate.

Table 6-1 LCCA Summary for Grinder Alternatives

Alternative	Capital Costs (Year 2027)			20-Year NPV of Capital Costs	O & M Cost Breakdown (20-Year Present Values)			20-Year NPV of O & M Costs	Salvage Value (NPV)	20-Year NPV
	Initial Capital Cost	Installation, Commissioning & Startup	Total Construction Cost		Electricity	Maintenance	Washwater			
Alternative 1 - Replace with new Washer/Compactor	\$225,000	\$415,000	\$640,000	\$545,000	\$10,000	\$80,000	\$130,000	\$220,000	(\$15,000)	\$755,000
Alternative 2 - Continue to utilize existing JWC Grinder	\$0	\$0	\$0	\$0	\$10,000	\$115,000	\$130,000	\$250,000	(\$15,000)	\$235,000

7.0 Summary, Recommendations, and Key Decisions

The goals task OKW-SCR-2 were defined as:

- Goal 1: Reduce amount of water flowing into grinder or dumpster when grinder is off-line
- Goal 2: Address problems with grinder/washer/compactor (grinder) discharge tube clogging between events

Based on evaluation of the existing screenings handling system and investigation into feasible equipment modifications, improvements, or replacement options, the following alternatives were developed:

- Reduce washwater pressure to 80 psi at the screens (Goal 1)
- Modify conveyor to add three drain sections (drain boxes) (Goal 1)
- Replace grinder with new Washer/Compactor (Goal 2)
- Continue to utilize existing grinder with modified discharge tube (Goal 2)

These are not separate, independent alternatives but a series of alternatives that could be applied in combination to achieve the improvement goals of the screens handling for the wet weather flows. With each alternative stated above to address the goal of reducing the amount of water being conveyed there is also the option the maintain the operation and equipment as-is and understand the trade-offs between reducing the washwater volume conveyed and not reducing the volume conveyed.

The Design Team recommends the following alternatives be implemented based on the analysis summarized herein, along with a brief description of the reasoning and/or remaining concerns associated with the selected alternatives:

- Maintain present screen washwater operating pressure of approximately 110 psi.
- Modify conveyor to add three drain sections (drain boxes)
 - The drain boxes are relatively low cost and short construction duration to install
 - Should address the large volume of water discharged to the screenings collection room when the screenings grinder is off-line
 - There is remaining uncertainty in the potential of the drain sections to clog with debris, effectiveness of the brush to keep the sections clear, and potential cleaning/maintenance required between events. (See next steps section for on-going effort to address this uncertainty)

- Continue to utilize existing grinder with modified discharge tube
 - This is the lower cost alternative, based on assumption that existing grinder does not need to be replaced within the project life cycle.
 - The equipment has been functioning well and meets the task goal to improve intermittent operation and prevent clogging of the discharge tube.

With the additional design storm total flow volumes of 4.5 to 5.5 times the current collection system configuration peak design storm volumes after the ODIRS is completed, the Design Team also recommends that GLWA monitor the volume of screenings collected during each storm event. Additionally, consider whether a larger dumpster and/or additional, dumpster change-out trained staff and equipment will be needed at the facility to reposition or change the dumpster during storm events.

7.1 Key Decisions

Below are the key decisions made by GLWA related to the Oakwood screenings conveyor and grinder system improvements:

- Addition of drain boxes to the conveyor trough to move forward into BOD phase
- GLWA will continue to use the existing grinder as modified with horizontal discharge tube
- No change to screen cleaning washwater pressure
- There is no further modification required to the existing modified screenings vertical chute

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Mohsen Sadatiyan, CDM Smith
Steve Fehniger, CDM Smith*

Date: June 1, 2023, Revised June 7, 2023

*Subject: TM-5 LEIB-SCR-1 Screening improvements and Pilot Screen
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) focuses on the study/evaluation of the screening system at the Leib Combined Sewer Overflow (CSO) Screening and Disinfection Facility (SDF) to improve screen reliability and functionality, including screenings conveyance. The evaluation included analysis of the existing screen operations (field investigations during wet weather, analysis/evaluation of available Ovation, operations and maintenance (O&M), or other historical data) in accordance with the original system design. The results of these analyses were used to determine recommendations that can improve screenings removal, improve screen functionality, and reduce the number of times the screens are overtopped. Based on the scope of this task (LEIB-SCR-1), the improvements include the following:

- Rehabilitation of the screen equipment in three of four screen channels
- Replacement of the screen equipment in one of the channels equipped with COPA® screens as a new pilot screen.

Table ES-1 summarizes the original design criteria from more than two decades ago and the design criteria based on the present system SWMM modeling and updated requirements.

Table ES-1 Design Parameters

Parameter	Original Design (1998)	New Design (Predicted 5-minute Peak Flow Rate)	
		present Condition	Future Condition (after Meldrum connection)
Hydraulic Capacity (cfs)	2,000	2,000	2,000
Screening Peak Flow (cfs)	1,550	520	950
Average Flow (cfs)	N/A	118	380
Peak Design Event	10-year, 1-hour event	10-year, 24-hour event	
Average Design Event	N/A	6-month, 24-hour event	
COPA® Blinding Factor	30%	50%	
ROMAG Blinding Factor	20%	25%	
Multi-rake Blinding Factor	-	30%	
Redundancy	None (all 4 channels in operation for screening peak design flow operating condition)	3+1 (one channel out of service for screening peak design flow operating condition)	

This TM presents the results of the evaluation of the existing screening system at Leib. The assessment consisted of a multi-faceted approach, including reviewing existing records of original design and construction, subsequent modifications, operating data and process video recordings, site visits, interviews and meetings with operations staff, and screening sampling efforts.

Based on evaluation of the existing system and communications with the screen manufacturers, the following recommendations are provided to improve the performance of the existing screen system.

- ROMAG control technology and instruments for actuating the hydraulic cylinders driving the cleaning combs were improved in recent designs. Based on the manufacturer's input, updating this component of the system can reduce the frequency of screen overloading faults. Also, replacing the hydraulic power packs can improve the reliability of these screens. In addition, lowering the bottom elevation of ROMAG screens by approximately 1-foot while maintaining discharge weir elevation at the current elevation allows the screen assembly to meet the manufacturer's recently recommended maximum through-bar (slot) velocity of 5 ft/s and could reduce cleaning mechanism faults.
- The technology of COPA® screens has not changed considerably in the last few decades. Accordingly, no other improvement options exist except for replacing the screens or their components with the same assembly, which is not recommended.
- In addition to the rehabilitation of ROMAG and COPA® screens, the system evaluation identified potential operation and control changes that could improve existing equipment

performance and reduce the frequency of overtopping. The primary recommendation is to run the equipment as much as possible on auto and allow 10% of the influent (aka side flow) to be conveyed to Toward Treatment Sewer (TTS) to reduce the accumulation of screenings upstream of these diversion-type screens.

- Calibration of the Influent flow meter, Toward Treatment flow meter, and Screening level sensor (which are critical instruments in screen and gate operation control) is recommended for reliable automatic operation.

Various alternatives were evaluated for a new screening technology from a technical feasibility perspective in alignment with project guiding principles. The evaluated alternatives are listed below:

- Alternative A: One multi-rake bar screen
- Alternative B: Two multi-rake bar screens installed perpendicular to the flow direction
- Alternative C: One center flow multi-rake bar screen
- Alternative D: Two overflow screens with screws
- Alternative E: Multi-rake bar screen and overflow screen
- Alternative F: Continuous element screens
- Alternative G: Replacing COPA® screens with ROMAG screens
- Alternative H: Facility expansion and major structural modifications

Based on the alternatives evaluation, Alternatives A and G, appear to be viable alternatives for the pilot screen and were selected for further economic comparison via life cycle cost analysis.

An extension of Alternative A and G for future consideration is summarized in this TM. Alternative G extension includes replacement of all COPA® screens in both channels with ROMAG screens that can provide screening capacity for 950 cfs peak design flow with one channel out of service. The extension of Alternative A will allow replacement of all remaining ROMAG and COPA® screens with similar multi-rake bar screens to meet the peak screening design flow of 950 cfs while one of the screening channels is out of service. This expansion will modify some flow paths through the Screening Inlet and Outlet Channels to convert the three existing middle Screening Outlet Channels to future Inlet Channels and two existing middle Screening Inlet Channels to future Outlet Channels.

Life cycle cost analysis conducted for Alternatives A and G for future scenario (all COPA® screens are replaced with new screens). It is assumed that Alternative A will be constructed in two phases. In Phase 1, the COPA® screens of the easternmost channel will be replaced with one multi-rake screen while the remaining screens will be rehabilitated. After 10 years, in Phase 2, all remaining

ROMAG and COPA® screens will be replaced with similar multi-rake screens. Alternative G is assumed to be constructed also in two phases. In Phase 1, the COPA® screens of the easternmost channel will be replaced with two ROMAG screens similar to existing at this facility, while the remaining screens will be rehabilitated. After 10 years, in Phase 2, the remaining COPA® screens will be replaced with two new ROMAG screens. The LCCA showed considerable (about \$3.96 million at the end of both phases) economic advantage of Alternative G over A on life cycle cost basis.

Advantages to Alternative G include limited structural modification, ROMAG screen's hydraulic capacity, and consistency of the equipment with what is already installed in this facility. The consistency of the screen technology not only has the advantage of operational familiarity, but also commonality of spare parts and understanding of maintenance needs. The life cycle cost analysis showed considerable economic advantage of Alternative G over A. The main driver for this considerable cost difference was limited structural modifications and capability of maintaining the existing ROMAG screen in service after some rehabilitation, including replacement of hydraulic power units and control and instruments for screen cleaning mechanisms, in Alternative G. Another advantage of Alternative G over A includes screenings capture capability with the smaller opening size of ROMAG screens (4-mm) in comparison to opening size with multi-rake bar screens (6-mm).

With the manufacturer recommended updates to the power pack, control panel, and new control logic, as well as operation of the facility in accordance with manufacturer recommendations for screen operation and providing the required side flow minimum of 10% through proper gate operation, Alternate G is technically feasible. Hydraulic analysis was completed to confirm that it is technically feasible for the system to produce the minimum 10% side flow within an acceptable headloss. Therefore, based on several advantages and lower cost, Alternative G, all ROMAG screens, is the recommended alternative to meet GLWA's goals and associated guiding principles for this project improvement item.

1.0 Introduction and Purpose

Completed in 2003, the Leib CSO SDF was constructed as a pilot to evaluate its effectiveness in screening and disinfection of overflows to the Detroit River. After nearly two decades of use and a long track of operation data, the facility screening processes require evaluation to determine the improvements within the constraints defined by the contract.

This TM focuses on the study of the screening system at the Leib Facility to improve screen reliability and functionality including screenings conveyance. This includes the analysis of the existing screen operations (field investigations during wet weather, analysis/evaluation of available Ovation, O&M, or other historical data) in accordance with the original system design. The results of these analyses will be used to determine recommendations that can improve screenings removal, improve screen functionality, and reduce the number of times the screens are overtopped.

Based on the scope of this task (LEIB-SCR-1) the improvements include rehabilitation of the screen equipment in three of four screen channels and replacement of the screen equipment in one of the channels equipped with COPA® screens.

The screen rehabilitation requires control panel upgrades and screen rebuilds (hydraulics, instrumentation, and hardware) for the remainder of the existing screens that will remain in place, as well as potential improvements to convey debris more effectively to the screenings collection channel. This includes rehabilitation of the screening mechanisms (screen, rakes, hydraulic rams, etc.), the hydraulic pumps, hydraulic tubing, and instrumentation associated with these screens. The improvements include updating the existing screens with the latest available technology to enhance system operation to be more resilient from becoming plugged and allowing flow to overtop the screen. The conveyance of screenings was also investigated for remaining existing deflection type screening systems.

The new pilot screen technology is to be installed in one of the existing COPA® screen channels. The designed improvements include necessary modifications to the screen channel and conveyance to allow the new screen to be installed. The designed and installed improvement will be evaluated to demonstrate that the selected pilot technology will effectively meet the Criteria for Success in CSO Treatment (1998).

Alternatives were evaluated for a new screening technology from a technical feasibility perspective in alignment with project guiding principles to identify a more reliable means of removing the screenings from the combined sewage and conveying the screenings into the screenings collection channel for transport to the Water Resource Recovery Facility (WRRF) through the Towards Treatment Sewer (TTS) which discharges to the Detroit River Interceptor (DRI).

The evaluation and study efforts include weather-dependent operations ride-a-longs to understand how the facility is operated, understand operational issues, and make recommendations for improvements. At the time of this writing no wet weather events had resulted in screen operation during the study phase.

The following sections will provide a description of the existing system description, a summary of the system evaluation and potential improvements for the remaining existing screens, alternatives analysis for the pilot screen, and the Design Team's recommendations for system and facility improvements.

2.0 Existing System(s) Description (and/or Conditions)

2.1 Background

The Leib CSO SDF was constructed as a demonstration CSO treatment facility as part of the City of Detroit's National Pollutant Discharge Elimination System (NPDES) Permit and its long-term CSO control plan. The facility is located east of Mt. Elliott between Waterloo St. and Kercheval St. It was designed to treat a total CSO flow of 1,550 cubic feet per second (cfs) with hydraulic capacity for flows of up to 2,000 cfs (to be conveyed through the facility with partial screening and disinfection

with less contact time). Flow conveyed to the facility is via the 16-ft diameter Mt. Elliott Sewer. The facility is a flow-through type receiving both dry and wet weather flows. **Figure 2-1** and **Figure 2-2** show the schematic of the facility and some upstream and downstream CSO system components.

Figure 2-1
Leib Facility Location Plan (DWSD, CS-1281, 2008)

Figure 2-2
Schematic of Leib Facility (DWSD, CS-1281, 2008)

2.2 Present Leib Wet Weather Operations

Under wet weather conditions, when the flow entering the facility from the Mt. Elliott sewer exceed the capacity of the 3-ft diameter outlet of the dry weather channel, the sewage begins to back up in the influent channel. At this stage, water flows into the facility and begins to rise in the Screening Chamber. When water levels rise above elevation 109' (about 12 ft deep), the dry weather gate closes, which leads to further flow accumulation and level rise in Screening Influent Channels.

If the level in the Screening Chamber exceeds elevation 110' (~13.0 ft deep), flow through ROMAG screens begins. At the same time, the screens will turn ON, the screenings channel gates open and the normally open SCUBA-actuated gates at the Leib Regulator Chamber will close. The combined sewage conveyed through the screens (screened flow) drops into the screened flow outlet channels associated with each screen and into the Disinfection Chambers. **Figure 2-3** shows the flow path of wet and dry weather flows through the facility. Under normal conditions, all screens are used to screen flows. Screenings captured by the screens continue to flow up the inclined screen channel and enter the screenings collection channel. This channel conveys the screenings flow to the TTS. As indicated in the project CS-1280 report, due to the elevation difference between Leib and the DRI, there will always be positive flow through the TTS to the DRI, even when there are high flows in the DRI. In anticipation that there may be high flows in the DRI caused by upstream wet weather, while there is no wet weather in the Leib tributary area, a gate is located on the TTS at the Toward Treatment sump. This gate will be closed if sensors indicate that flow from the DRI may back up into Leib.

The control system automatically turns the screens and mixers off as wet weather flows subside and when the level in the Screening Chamber drops below elevation 109.8' (~12.8 ft deep). Water remaining in the facility flows out through the TTS to the DRI. When sensors confirm that capacity exists in the DRI, a gate at the regulator on the Leib sewer at Jefferson Avenue opens, allowing water remaining in the Leib outfall sewer to flow into the DRI. When the Leib outfall above the DRI has completely drained into the DRI, system operators activate the dewatering pumps at Harbor Town, and water remaining in the Leib outfall sewer at a level below the DRI is pumped back into the DRI. Also, at this time, the Great Lakes Water Authority (GLWA) personnel may enter the screening and disinfection chambers to wash down remaining solids to the TTS.

Figure 2-3
 Leib Facility Process Nomenclature, Layout and Flow Path (GLWA, CS-299,2021)

2.3 Screens

The Leib facility has two types of deflection-style bar rack screens, each with 4-mm thick stainless-steel bars with 4-mm spacing. A total of 12 screens are installed in the four Screening Inlet Channels. Two channels are equipped with ROMAG screens (two screens per channel), and the other two are equipped with COPA® screens (four screens per channel). Both types of screens share the same purpose of mechanically screening flow passing through bar openings and discharge the screenings removed from screen field back into the Screening Inlet Channels which are connected to the Screening Collection Channel for transport to the WRRF through the TTS and DRI.. The ROMAG screens have a vertical arrangement, with flow moving horizontally through the bars and falling to Screening Outlet Channel (**Figure 2-4**).

Figure 2-4
Horizontal COPA® (left) and Vertical ROMAG (right) Screens

The COPA® screens have a horizontal arrangement with flow conveyed up vertically through the bars and overflowing to the Screening Outlet Channels. Each screen consists of bar screen assemblies, cleaning carriage (comb for ROMAG and rake for COPA®), overflow weir, hydraulic power pack, and controls. ROMAG screens are also equipped with inclined flow control weir plates on the downstream side to prevent flow through the screen unless the water level reaches almost its mid-height.

2.4 Screen Hydraulic Power Packs

A separate hydraulic power pack drives each screen's hydraulic cylinder. The power packs are in the Mechanical Equipment Room, above and on the north side of the Screening Inlet Channels

(Figure 2-5). The control panels for the power packs are located directly on the other side of the wall in the Electrical Equipment Room. Each hydraulic power pack includes a hydraulic gear pump with a suction filter powered by an electric motor. Each hydraulic power pack has 10-gallon capacity oil reservoir filled with vegetable-type hydraulic oil. In addition, each unit is equipped with a 0-3,000 psi pressure gauge, pressure limiting/relief valve, replaceable oil filter, filler/ breather cap with strainer, and combination level and temperature switch. All connection fittings between hydraulic hoses and other system components are stainless steel. In addition, the ROMAG hydraulic power packs are equipped with an emergency shutdown pressure switch should the pressure in the hydraulic lines exceed a specific manufacturer set point.

Figure 2-5
Hydraulic Packs for ROMAG (4 on the left) and COPA®(8 on the right, two rows one below and one above)

2.5 Screen Channel Gates

At the end of each screen inflow channel, the outlet gate allows a portion of the influent flow to be conveyed to TTS. **Figure 2-6** shows these gates at the south end of ROMAG and COPA® Screening Inlet Channels. These stainless steel upward-opening electrically actuated slide gates can be opened automatically or manually (whether remote from Ovation or locally from the actuator local control at each gate). Based on the conducted field test and a review of operation video recordings, gate travel time is approximately 4 minutes to open these gates from 0 to 100%.

Figure 2-6
Screening Channel Gates for ROMAG (left) and COPA® (right)

2.6 Initial Design Goal and CS-1281 Evaluation of the Facility Performance

Based on this facility's original design and subsequent evaluation records, Criteria for Success in CSO Treatment was issued in 1998. The Criteria for Success document was developed initially for use in conjunction with evaluations of the Rouge River CSO Demonstration Basins. The document specifies procedures for evaluating Phase II CSO Control goals outlined by the NPDES permit for CSOs within the Rouge River watershed. These criteria were used as a guideline for assessing the Leib CSO SDF ability to meet Phase II requirements during discharges to the Detroit River from 2003 to 2005 as part of the CS-1281 project.

The Criteria for Success document specifies that a CSO control facility would be considered to eliminate raw sewage discharges if the treated effluent did not appear as raw sewage. In accordance with this criterion, the sampling plan for the screening and disinfection facilities included the use of 4-mm mesh sample bags (Copasacs) to measure the ability of the fine screens to achieve "operationally complete" removal of sanitary trash from the effluent. Two screening events (each 3 hours or less) from 6/2003 to 6/2005 took place that each resulted in under 400 cfs peak flow.

The evaluation report indicates that only flow that passes through the screens is considered influent to the facility because flow up to approximately 200 cfs passes to the DRI via the TTS upstream of the screens. This toward treatment flow is roughly equivalent to the flow entering the DRI before facility construction through the Leib regulator gates, which are now closed during events. It was observed that approximately 50-100 cfs of influent flow is necessary to convey

screenings away from the facility effectively. It also indicated that two of the eight COPA® screens stopped functioning near the end of one of these two events. However, these failures did not cause flows to pass unscreened, overtop the screens, or otherwise receive insufficient screening. No identifiable difference was observed between the performance of the COPA® and ROMAG screens operating in parallel at Leib.

3.0 System Evaluation

To evaluate the condition of the Leib Screening system, a multi-faceted approach was taken that included:

1. Three site visits, which included checking the equipment condition and discussing the facility's operation and maintenance with GLWA team members.
2. Preparing existing screenings sampling devices to obtain an improved quantitative and qualitative understanding of the screens performance and capture rate during wet weather events.
3. Collecting and analyzing the facility's last 3 years of operating data (from January 2020) to better understand how equipment reacted to the wet weather events.
4. Collecting and reviewing the video recordings of the last five wet weather events (during 2021 and 2022) to observe the typical equipment operation during the event and identify anomalies.
5. Conducting meetings with operations staff to focus on standard operating procedure (SOP) and O&M procedures in practice and discuss the findings from the review of operating data and video recordings.

These evaluation activities and their outcomes are described briefly in the following sections.

3.1 Site Visits

During the site visits on 11/10/22, 11/1/22, 10/20/22, and 2/27/23, the screening system component's condition was visually inspected, and operation and maintenance items were discussed with day and night shift staff.

In general, the condition of various system components, including ROMAG and COPA® screens structure, cleaning mechanism, combs, rakes, weirs, hydraulic power packs, lines, gates, and actuators, and associated instruments, visually appear to be in good condition. No significant wear, corrosion, or erosion were observed. A few signs of hydraulic oil leaks were observed on a couple of screen support walls related to past incidents of tube leaks. It appears that limited facility activations in combination with commendable housekeeping, resulted in the relatively untarnished condition of the system components. With the exception of some signs of corrosion on the structural truss supporting the catwalk above the screens, there were no significant signs of corrosion or harsh atmospheric environment in the basement or upstream area of the facility.

Based on discussions with operators, there is not a single fault on any piece of equipment that can be indicated as the leading cause of the system operation interruption during wet weather events. However, further discussion of the historical trend of issues indicated that, in general, overloading of the screening cleaning mechanism and issues with leaks or faults of the hydraulic power units may be the leading cause of screen operation interruption during wet weather events.

Operators indicated that the largest object observed in the influent in the last few years of operation was a small traffic cone. Typically the influent does not contain large objects.

There was one event that resulted in screen activation since June 7, 2022, which occurred on February 27-28, 2023. The analysis of the screenings sampling, gate positions, and toward treatment flow from this event is summarized in the next section

3.2 Screenings Sampling

The existing screening sampling devices downstream of each screen and also downstream of the screening chamber are used to take screenings samples during a wet weather event. Proper-size sampling nets were obtained, and the existing sampling devices were cleaned and equipped with nets to capture material that may escape screens during an event. In general, the sampling and analysis methodology of CS-1281 (2004 to 2008) project were used for this effort. **Figure 3-1** shows sampling nets installed downstream of a COPA® screen and in screening chamber.

Figure 3-1
Sampling Nets Installed Downstream of COPA® screen (left) and in Screen Outlet Chamber (right)

However, due to the low frequency of this facility activation, from June 2022 to March 2023, there was only one wet weather event that resulted in the activation of screens. The event started on the evening of 2/27/2023 and finished on the morning of 2/28/2023. The event resulted from 0.75

inches of rainfall over about 9 hours. During the operation ride-along of this event (from the 1st to 4th hour), inflow as high as 394 cfs was observed. All 12 screens of 4 channels were in operation without overflow. All four screening channel gates were 100% open, and the Toward Treatment gate was 12.5% open. The dry weather gate was also open, and the total flow conveyed to TTS fluctuated between 57 to 98 cfs. During the operation ride-along, it was observed that the screen cleaning mechanisms were working. The screen field looked clean with limited screenings accumulation, and with the screening channel gates 100% open, the screenings were moving to TTS. The flow to the TTS visibly has more screenings (wipes, floatable, etc.) than the flow conveyed to the Disinfection Chamber. However, based on net samples, it seems some material was getting through the screens, especially if the item was one or two dimensions was smaller than 4 mm screen openings. **Figure 3-2** shows the location of 12 nets installed downstream of screens. The net assemblies have 1 foot by 1 foot flow path openings and about 3.5 mm by 3.5 mm net holes. The weight of captured material in these nets during the whole event varied from 0.4 to 1.2 pounds. In general, it seems the amount of materials passing through screens is increasing from the west channel to the east channel. The captured material in nets includes decomposed wipes and toilet paper, leaves, wood chips, twigs, fabric, plastic, cement pieces, paint pieces, plastic wraps, and seeds, with one folded N95 mask found in the S6 net. The smallest dimension of each captured item was not larger than 3 mm however the larger dimension of some items like twigs could be as much as 60 mm (mostly in one dimension). **Figure 3-3** shows a view of 12 sampling nets after the event and a sample content of captured materials.

Figure 3-2
Installation locations of screenings sampling nets

Figure 3-3
Top face of all sampling nets (top) and content of S1 net (bottom)

3.3 Operation Data Analysis

Collecting and analyzing system components' operating data during the last 3 years, from January 2020 to January 2023, provided a better understanding of the system operation. The analyzed data included the following:

- Three flow sensors: Influent, Toward Treatment, Outfall Sewer
- Six level sensors: Influent, Screening, Mixing Chamber, Outfall Lower Sewer, Outfall Upper Sewer, Upper DRI
- Seven gates position: Screening Outlet Gates 2, 4, 6, and 8, Dry Weather Gate, Disinfection Chamber Drain Gate, Toward Treatment Gate
- Twelve screens: Auto, Overflow Fault, Run

A data review showed many instances that one or multiple sensors' data was unavailable through the data archive or the reported values were unreliable or erroneous. However, analysis of data from various sensors at the same time showed that with high certainty, there were ten wet weather events in the last 3 years, which resulted in screen activation. The data analysis showed various irregularities in the operation of screens and gates, which did not match the expected operation per facility SOP and O&M documents. Based on the SOP and O&M, it was expected that all screens turn on when the water level in Screening Chamber reaches about elevation 110' (~13 ft deep). At this time, all four Screening Outlet Gates open, the Dry Weather Gate closes, and the Toward Treatment Gate changes position from 100% to 12% open. Also, it was expected that the opposite of all these actions would happen when the water level in Screening Chamber drops below elevation 109.8' (12.8 ft deep). However, analyzing data from a few recent events during the last three years showed the screens did not start at the expected level, and if started, shut down soon, after a few minutes in some cases. Also, the TTS gate was closed for a long duration of the event. Ovation data points that were used in this analysis include influent, outfall and TTS flow, influent, screening, mixing chamber and TTS levels, screen outlet gates, 2, 4, 6, 8, dry weather gate and TTS gate positions, screens 1 to 12 fault and run status. For instance, **Figure 3-4** shows the status of screens, TTS gate, and influent level & flow in addition to the TTS level and flow for a screening event from 6/7/22 to 6/8/22. During this event, no screen fault is recorded on Ovation. The TTS gate is closed, and flow to TTS is almost zero from around 5 AM to 11 PM of 6/7/22, while the influent flow, level, and screening level are high. All screens turned on early in the event and then turned off, and some of them came back on and off during the event for short periods of time.

Figure 3-4
Ovation historian data for Leib screening event on 6/7/22 to 6/8/22

Table 3-1 lists the summary of data related to each screening event in the last 3 years. Many irregularities can be seen where system responses do not match the expected system component status based on SOP and O&M.

3.4 Video Recording Review

The video recordings of five out of the ten screening events from January 2020 to January 2023 were provided by GLWA. A review of the video recordings also showed some equipment operation irregularities, system responses that were not matching the expected system operation per SOP and O&M. Based on SOP, it was anticipated that lights turn on and video recording would start as soon as screens turn on, and the light turns off, and video recording stops when screens turn off. The summary of the video recording review and observed anomalies are shown in **Table 3-1**.

Table 3- 1 Summary of Leib Screening Event Information from January 2020 to January 2023

Event Date	6/7/2022	10/25/2021	9/22/2021	8/12/2021	7/24/2021	7/16/2021	6/26/2021
24 hours Rain	1.97"	1.04"	0"	1.73"	1.33"	2.72"	4.73"
Video Recording Available?	Yes (4 hrs.)	Yes (2.5 hrs.)	Yes (2 hrs.)	No	No	Yes (4 hrs.)	Yes (1 hr.)
Max Influent Flow During Event, cfs (based on Ovation)	910.93	n/a	n/a	649.99	404.27	1087.86	551.81
Max Influent level During Event, ft (based on Ovation)	17.92	18.45	18.40	16.87	16.84	18.45	16.50
Screening Event Duration hr: min	7:05	7:24	12:17	11:30	6:39	8:16	10:30
Avg TT Gate Position During Event, % open (based on Ovation)	49.95	26.06	0.00	24.75	96.83	11.45	29.04
Screening Channel Gates	Gate 2 closed, other three open for 1 min	all open for 1 min at the beginning of the event, then closed for the remainder	all closed	all closed	all closed	Gates 2, 4 & 6 were open 3 hours after the start of the event until its end; the other one stayed closed	open 15 min after the screen start and stays open for the whole event
ROMAG	All ran periodically for short intervals during the event	1 & 2 never ran, 7 & 8 ran except the last 1-2 hours	All ran only during the 1st hour of the event	Only seven ran during the event, except for the 1st hour	All never ran	1 & 2 never ran, 7 & 8 potentially overloaded after ~1 hr	All except 1 ran during the whole event
COPA®	All ran periodically for short intervals during the 1st 3.5 hrs. of the event, then ran continuously for the 2nd 3.5 hrs. of the event.	Three only ran during the 1st half an hour of the event. The rest ran the whole event.	All ran during the entire event	All ran during the event except the 1st hour	All ran during the whole event	All ran during the entire event	All ran during the whole event
Known operation issue based on operator notes	Hydraulic line leak, power loss	Power packs has issue and filter cup was leaking	No issues	Overload fault for screens 1 & 2, Hydraulic issue for screen 8	Remaining issues from 7/16	2, 7, 8 had issues and couldn't ran even on manual	Many issues resulting in screen and hydraulic unit repair and replacement of hoses, ROMAG combs and COPA® rakes

These observed operation anomalies could potentially contribute to the screen overflowing that was observed in all five events.

3.5 Operator Meeting

After a desktop study of SOP, O&M, project records, site visit records, and analysis of archive operating data and video recordings, a meeting was arranged to discuss the results of the analysis with the operation team. Comparing notes with staff who have been leading the operation of this facility over the last ten years confirmed the ten-identified screening events in the previous 3 years. Also, various causes were identified that could explain several of the irregularities observed in archived operating data and video recordings. The main contributors to these irregularities were Ovation communication loss or faulty signal from instruments, oil leak and hydraulic unit fault, screen overload, and power loss. Also, during a meeting on 1/26/23, it was indicated that typically operators leave the Toward Treatment Gate or Screen Channel Gates completely closed during the wet weather event to prevent adding flow to DRI. Considering that all existing ROMAG and COPA® screens are deflection-type screens that need active side flow to TTS to prevent screenings accumulation on the face of the screen, preventing flow to the TTS results in screen clogging and overloading.

Further discussion with GLWA operations and engineering staff indicated that there is no fixed limit on the amount of water that can flow from the Leib facility to DRI during the wet weather. However, the currently established protocol is to position the Toward Treatment Gate about 20% open to limit the excessive water flow to DRI in wet weather conditions.

Table 3-1 lists a summary of critical information collected during the meeting with operators. Discussion of the significant improvements and maintenance conducted on the screens revealed the recent replacement of hydraulic hoses of all screens from the power pack to the solid pipes. In addition, staff indicated that the cleaning combs of ROMAG and rakes of COPA® screens were replaced recently. This rehabilitation activity was conducted in mid-2021 after major screening issues were observed during the wet weather events on 6/26/2021.

4.0 Improvements of Existing Screening System

Based on existing system evaluation and communications with the screen manufacturers, recommendations are provided below to improve the performance of the existing screen system. The goal is to make the system more reliable and enhance debris removal to allow the screens to maintain function throughout events to reduce the frequency of screen overtopping.

4.1 ROMAG Screen Improvements

ROMAG is one of the dominant screening products in the market for deflection-type screens. They have a track record of installation in North America and are still active in this market under SAVECO representation. Their present local representative in Michigan is Peterson & Matz Inc., which is familiar with the equipment in this facility. Their control technology and instruments for actuating the hydraulic cylinders driving the cleaning comb were improved in recent designs. Based on the manufacturer's input, this modification can reduce the frequency of screen overloading faults by decreasing the chance of shortening the cleaning mechanism strokes. The updated control features includes:

- Short Stroke detection / alarm
- Blocked clean rake/carriage detection / alarm
- Rakes parked at home to allow for maximum cleaning force upon initial startup
- Pressure monitoring and individual set points for controlling rake/carriage in each direction
- Repeat cycle timer
- Allows for control of upstream level sensor setpoints to control screen cycle
- Running the screen cleaning mechanism faster

Also, replacing the hydraulic power pack and possibly its piping could improve power delivery from the unit to the screen cleaning mechanism with reduced pressure loss. This, in combination with providing the required power to clean screenings from screen field and the proper speed of the combs, can reduce the potential for over-pressurizing fault and tripping the unit.

The operation of the ROMAG screens will also be improved by providing the required minimum 10% side flow to convey screenings to the toward treatment sewer and out of the screenings collection channel. Hydraulic analysis performed by the design team, concluded that it is technically feasible to provide the minimum 10% side flow with the screenings channel gates and the toward treatment gate positions set properly, as described further in Section 4.4. As described in Section 3.2, the desired minimum side flow was also exceeded during the 2/27-2/28/23 wet weather event which activated screen operation. The hydraulic evaluation also showed that the headloss through the facility was acceptable while achieving the 10% minimum side flow.

According to the manufacturer's recently identified requirement, exceeding a through-bar (slot) velocity of 5 ft/s can negatively impact the screen's cleaning mechanism, potentially causing the accumulation of screenings and lead to faults. To facilitate slot velocity remains below 5 ft/s during the peak screening design operating condition, the manufacturer suggested lowering the bottom of the screen by approximately 1-foot while maintaining the existing elevation of the top of the discharge weir. Implementing this change requires limited structural modifications, including the removal of 1-foot of concrete wall beneath the screens that will allow reinstalling screens at the lowered elevation. Additionally, the discharge weir plate on the downstream face of the screen requires replacement. These modifications will result in a larger portion of the screen face being submerged during peak flow conditions, effectively reducing the slot velocity. This alteration will not have an impact on the upstream water surface elevation since the elevation of the top of the discharge weir remains unchanged in this configuration.

The possibility of replacing the existing rakes with 4-mm screen openings with new rakes with 6-mm screen openings was discussed with the manufacturer. Although ROMAG is not recommending the 6-mm openings, and they typically use the 4-mm openings for CSO applications, they can provide 6-mm openings. The 6-mm opening is the typical opening size of CSO facilities using other screen technologies and is commonly one of the smallest sizes of screen openings considered for CSO facilities. Changing the opening size from 4-mm to 6-mm has advantages and disadvantages. Having a narrower opening can increase the capture rate. Also, the close distance of two bars provides a support mechanism for the wider flat shape debris (e.g., leaves, wipes, paper, etc.) that increase the potential capture. A wider gap between the bars may result in flat or stringy-type debris wrapping around the rake that might be harder to clean from the screen surface by the cleaning mechanism. This wrapping condition was of concern to ROMAG representatives. However, 6-mm openings reduce the potential of screen clogging and can improve the hydraulic throughput of the unit and reduce the slot velocity. In this case, although finer material might pass the wider openings, in general, due to reducing the potential for screen clogging, high slot velocity, and reduced probability of overtopping, the screenings capture performance during the entire event may increase. Based on the above considerations, the design team recommends maintaining 4-mm openings.

The Design Team's review of recent installations of similar ROMAG equipment in other parts of the country showed that although the new equipment is not working flawlessly, the number of faults and overtopping are limited.

4.2 COPA® Screen Improvements

The official supply of COPA® screens to North America has been interrupted in the last decade. The company does not have an official representative or installation list for new equipment installations in the United States (U.S.). Furthermore, based on the discussion with the company United Kingdom (U.K.) headquarter staff, the technology of these screens has not improved considerably in the last few decades. Accordingly, no other improvement options exist except for replacing the screens or their components with the same assembly.

The engineer's inquiry of other COPA screen installations in the U.S. after the original construction of this facility did not find a successful example of COPA screen implementation for CSO applications.

Considering the relatively untarnished condition of the existing COPA screen and the plan to replace half with a different type of screen as part of this project pilot screen evaluation, it is not recommended to replace the remaining COPA® screens in kind. However, due to the safety risk associated with cleaning the COPA® screens after the event from the top of the screen, it is recommended that permanent fall arrest/protection tie point be provided on top of the remaining COPA® screen equipped channel. This could help operators and maintenance staff to have an additional and accessible safety protection device in case they need to climb on top of the Copa® Screening Channel via the lower Screening Outlet Channel.

4.3 Screenings Channel Gate Improvements

As discussed in the previous section, visual inspection and dry run of the Screenings Channel Gates demonstrated operational equipment in good condition. Gates appear to be well maintained. Based on the present condition and travel time the gate system equipped with electric actuators a change to the equipment or the actuation system was not identified as beneficial to enhancing performance.

Replacing the upward opening gates with rectangular butterfly gates, in theory, can give more control to take the flow to the TTS from an area closer to the surface of ROMAG screens instead of from the middle of the channel. This, in theory, can help increase the efficiency of washing away the screenings accumulation from the face of ROMAG screens.

Discussions with the manufacturer showed no positive experience with the concept of using rectangular butterfly gates. The lack of practical evidence for benefit and the need to change the gates for two channels while the gate for the COPA® channel needs to stay the same (due to the screen arrangement) led to disregarding this option. In addition, implementing this option could increase the complexity of the operation and maintenance of the system and might lead to some operation and maintenance challenges due to wrapping screenings around the gate, and may not have a sensible positive outcome.

4.4 Control and Operation Improvements

In addition to the rehabilitation of ROMAG and COPA® screens the review of operating data, operations discussions, and Design Team observations indicated potential operation and control changes that could improve existing equipment performance and reduce the frequency of overtopping.

The main operational change focuses on providing a flow path for about 10% of the influent flow to wash down the captured screenings from the screen field to the TTS. The existing deflection-type screens require this flow to prevent the accumulation of screenings upstream of screens that eventually result in screen clogging, cleaning mechanism overload, and screen overtopping. ROMAG

representatives recommended a minimum of 10% influent flow. This number is recommended for this application to meet the minimum requirement of the deflection type screen while minimizing conveyance of an excessive amount of flow to DRI during a wet weather event. In addition, the automatic controls of screens should be set to activate the ROMAG and COPA® screens as soon as flow reaches the discharge weir of the ROMAG screens; at the same time, Screenings Channel Gates need to be opened fully while the Dry Weather Gate is closed, and the position of the Toward Treatment Gate should be partially closed so 10% of the influent flow is conveyed to the TTS. Based on discussions with the GLWA CSO operations and engineering teams, a 20% open Toward Treatment Gate is not expected to have an adverse effect on the downstream DRI during a wet weather event. Considering the peak design flow of 950 cfs (after Meldrum St. connection), about 95 cfs needs to be conveyed to TTS for proper transfer of screenings away from the screen field. The Toward Treatment Gate open position should be adjusted based on the influent flow to the facility and TTS flow to keep the TTS flow about 10% of the influent flow if feasible within the maximum gate open during wet weather event constraint.

It is important to note that the screenings channel gates provide a flow path to the screenings collection channel. However, the opportunity to control flow rate from each screen channel to the screenings collection channel is limited if system complexity is not increased as part of the improvements. Presently instrumentation is not in place to allow determination if the appropriate flow is being conveyed given the deflection screen flow split varies between the technologies resulting in the side flow rate varying accordingly to meet the 10% minimum. This is a limitation of the system resulting in inability to provide inputs to determine gate position to throttle flow to achieve 10% discharge to TTS from each channel relative to the influent flow through each screen. In addition, the throttled gate may cause screenings to back up if the majority tend to float in the upper portion of channel.

It is recommended that operators be discouraged from running screens and gates manually (whether local manual or remote manual) unless the Ovation communication or instrument issues prevent the automatic operation from functioning as expected. Also, to provide a greater flow path area through the screens and reduce the potential for clogging, it should be considered to run all screen cleaning mechanisms at the manufacturer recommended speed during the automatic operation. The cleaning mechanism of existing ROMAG and COPA screens has only a one-speed option. However, other technologies (e.g., multi-rake screens) can provide an option for running the cleaning mechanism at low or high speeds.

At the end of the wet weather event, with a few minutes delay after the water level in the screening influent channel drops below the elevation of the discharge weir screens, all screens should be turned off, and the Screenings Channel Gate closed at the same time.

The Disinfection Drain Gate remains closed during events as it is only used for Leib dewatering.

4.5 Field Instrument Calibration and Backup Monitoring Options

Calibrating the Influent flow meter, Toward Treatment flow meter, and the Screening level sensor (which are critical instruments in screen and gate operation control) is very important for successful automatic operation. To protect screens from running dry (which is harmful to, the screens, particularly the ROMAG screens), when the screening level sensor reads faulty unrealistic high-water level, the backup level switches for high and low levels can be used. Alternatively, a combination of signals from other sensors (e.g., Influent or Outfall Sewer flow, Mixing Chamber level, etc.) could be used as a verification or as a backup of the Screening level sensor readings.

5.0 Description of Pilot Screen Alternatives

Various alternatives were evaluated to replace the existing COPA® screen in one of the Screening Inlet Channels with a new technology or installation. These alternatives are described in the following subsections.

5.1 Design Criteria

Table 5-1 summarizes the original design criteria from more than two decades ago and the design criteria based on the present analysis and updated requirements.

Table 5-1 Design Parameters

Parameter	Original Design (1998)	New Design (Predicted 5-minute Peak Flow Rate)	
		Present Collection System Configuration	Future Configuration (after Meldrum connection)
Hydraulic Capacity (cfs)	2,000	2,000	2,000
Peak Flow (cfs)	1,550	520	950
Average Flow (cfs)	N/A	118	380
Peak Design Event	10-year, 1-hour event	10-year, 24-hour event	
Average Design Event	N/A	6-month, 24-hour event	
COPA® Blinding Factor	30%	50%	
ROMAG Blinding Factor	20%	25%	
Multi-rake Blinding Factor	-	30%	
Redundancy	None (all 4 channels in operation for peak design flow operating condition)	3+1 (one channel out of service for peak design flow operating condition)	

The original peak design flow capacity of 1,550 cfs for screening was considered to go through all four Screening Inlet Channels with all 12 screens in service. However, based on the latest revision of the Recommended Standards for Wastewater Facilities (Ten States Standards, 2014), this facility is to be designed with the capability to screen peak design flow with one unit (channel) out of service.

The original design basis utilized 30% and 20% blinding factors for COPA® and ROMAG screens, respectively. Peak design flow of 1,550 cfs total with, flow split through each COPA® (410 cfs) and ROMAG (365 cfs) screens Inlet Channel.

The communication with COPA® and ROMAG manufacturers and using their most up-to-date blinding factors and formulas indicated that a 50% blinding factor for COPA® and a 30% blinding factor for ROMAG screens are more representative values for the real operating condition of these types of equipment.

The updated SWMM model of the upstream watershed and historical wet weather records of the last two decades were studied as part of this project, and the 5-minute peak design flow of 950 cfs based on 10-year, 24-hour design event is considered for this improvement design (includes future Meldrum St. connection). The average flow is determined to be 380 cfs (includes future Meldrum St. connection). To meet the Ten States Standards requirements, the peak flow needs to be screened with one Screening Inlet Channel out of service.

5.2 Multi-rake Bar Screens

This technology incorporates a fixed screen field with bars installed between 45-degree to nearly vertical angle. Multiple rakes clean the screen field with teeth that engage into the space between the bars and travel over the screen field frequently (every 5 to 10 seconds for some screens). The rakes are attached to a chain that rotates in front of the screen. The screenings are lifted by the rakes and discharged off the back of the screen. Manufacturers of multi-rake bar screens on the U.S. market include the MS screen by Headworks® (see **Figure 5-1**),; the FlexRake® by Duperon®; and the RakeMax® by Huber. Despite Duperon's advantages of having a headquarter in Michigan and lack of a submerged lower sprocket, based on challenges at other applications at 6-mm and limited cleaning speed when plan to run at max speed continuously, the FlexRake® receives a lower ranking in comparison to Huber and Headworks product for this application. The following subsections describe three alternatives for various installations or types of multi-rake bar screens which are applicable to this site.

Figure 5-1
Multi-Rake Bar Screen (Headworks® MS-1)

Multi-rake bar screens have a lower screenings capture ratio than other perforated or mesh screens due to removal in one dimension only. However, the screens are more rugged and appropriate for wastewater or combined sewage applications. In addition, this technology has lower head loss compared to other screening technologies. Finally, this type of screen has a long track of successful installation in various capacities. These are some advantages and disadvantages of multi-rake bar screens:

- Advantages
 - Multiple rakes are attached to the chain to permit quick cleaning of the bars and reduce screen blinding
 - Very low headroom requirements with only the motor, frame, and doctor blade mechanism located above the screen discharge point
 - Medium footprint due to recommended inclination angle (as low as 45 degrees up to 90 degrees, typically 75 degrees)
 - Lower head loss compared to other screens

- Deep installations are possible and have been done previously. Also, installation in segments is possible in case of limited available space for installation and rigging
- A VFD can control the motor drive to moderate the rate at which the rakes clean the screen field
- Availability of clear bar spacing as low as ¼-in (6-mm) for combined sewage
- Some manufacturers do not include a lower submerged sprocket (Duperon Flexrake®) which is more convenient for maintenance and limits maximum operating speed
- High screenings loading rate and flow capacity
- Holds up well to high-grit applications
- Disadvantages
 - Submerged lower sprocket and bearing (typical installation for most manufacturers except Duperon Flexrake®) can be hard to access for maintenance. However, technological innovations have significantly increased the durability of submerged components. For example, the lower sprocket and bearing are a self-lubricating design, and grease lines are not required. For instance, based on information from Headworks®, the lower sprocket assembly utilizes an exclusive self-lubricating ceramic bearing. The assembly is maintenance-free, highly wear-resistant, and covered by a 5-year warranty. Units have been in operation for ten years without any parts replaced. The screen can be operated in dry conditions without damage to the sprocket and bearings. However, long periods of dry operation are not recommended as the hard ceramic bearing could cause wear on the stainless-steel shaft. For this application, which is dewatered between events, access to the lower components is more readily feasible than in continuous duty applications.
 - Screen remains in one position for long periods without flat spotting the bearing or shaft in this arrangement. However, exercising the screens on a regular interval, which the control system can automatically perform, is recommended to create a movement of other parts (i.e., the chain and motor) and verify the screen operates.
 - A large amount of stringy material could wrap around the lower sprocket and cause it to stop turning, thereby causing a torque overload shut-down.
 - Annual to semi-annual inspection recommended.
 - Ultra-High Molecular Weight polyethylene (UHMW) turnaround shoe is available as an alternative to the sprocket assembly; however, the shoe is much more susceptible to wear

from grit and would end up being replaced three to four times before a sprocket would need to be maintained.

5.2.1 Alternative A: One Regular Type Multi-Rake Bar Screen

This alternative includes installing a multi-rake bar screen toward the south end of the easternmost screening channel to replace the four existing COPA® screens (No. 8 to 12). **Figure 5-2** shows the arrangement of the new screen and its screening discharge chute in plan and section views. Huber RakeMax®, and Headworks® MS series all can provide multi-rake bar screens for this application, including the extended chute.

In addition to removing the COPA® screens, installation of a new screen for this alternative would require structural changes as follows:

1. Removal of the stepped concrete fill in the Screening Inlet Channel
2. Removal of the existing Screening Outlet Gate and close opening. To seal the existing concrete opening, adhesive dowels and a hydrophilic waterstop will be installed around the perimeter of the existing openings. The opening will then be filled with reinforced concrete.
3. Adjustment of the elevation of the top of the walls of both sides of the Screen Inlet Channel.
4. Modification of the platform and walkway around the screen and its discharge chute to resolve conflicts.
5. Creation of a new opening on the lower part of the channel wall for screened combined sewage to flow downstream of the screen to the Mixing Chamber. This opening can be created either on the south end wall of the Screening Inlet Channel for a flow path under the Screening Collection Channel or on both the east and west walls of the Screening Inlet Channel. If this alternative is selected the size and location of the wall openings will need to be refined and further coordinated with disinfection unit process in future design phases. The opening invert should be at the same level as the concrete floor of the channel to allow discharge and flushing of potential sediment. The chambers containing walls where new openings are required will be required to be fully drained during construction. Once drained, the new openings can be cut into the existing concrete wall. The existing rebar will need to be drilled back into the concrete wall and sealed to prevent corrosion. Depending on the final size and location of openings, additional structural strengthening or stiffening may be required.
6. Creation of a small opening on the north wall of the Screening Collection Channel for the screenings chute discharge point to this channel.

Figure 5-2
Alternative A Plan (Top) and Section (Bottom) Views (Duperon)

5.2.2 Alternative B: Two Multi-rake bar Screens Installed Perpendicular to the Flow Direction

This alternative includes installing two multi-rake bar screens perpendicular to the flow path of water. The two screens can be installed either face to face on both East and West sides of the Screening Inlet Channel or side by side, both on the south wall of the Screening Inlet Channel.

Figure 5-3 shows the former face-to-face arrangement of the new screens and its screening discharge sluice channel in plan and section. Headworks® indicated their MS-1 multi-rake bar screens can be installed in this arrangement, including the required sluice chutes.

The structural changes required for this alternative are similar to Alternative A. However, the extent of change items 5 and 6 is broader for this alternative. The wall opening for installing screens in this alternative affect the full height of both the east and west walls of the Screen Inlet Channel. Also, there would be two openings for the discharge point of the sluice chutes on the north wall of the Screening Collection Channel.

Figure 5-3
Alternative B Plan (Top) and Section (Bottom) Views for Headworks screens

5.2.3 Alternative C: One Center Flow Multi-Rake Bar Screen

This alternative includes installing one center flow multi-rake bar screen toward the south end of the Screening Inlet Channel. **Figure 5-4** shows the plan view of this alternative with a sketch of this specialized type of multi-rake bar screen. In this installation, incoming flow from the Screening Inlet Channel impacts a dead-end plate in the screen, causing the flow to turn 90 degrees and be conveyed through U-shaped bars of this multi-rake bar screen located at the center of the channel. Two side plates at the inlet point of the screen guide the flow toward the center of the U-shaped screen. The rake mechanism rotates around a closed chain loop to clean the screen from one side of the U-shaped bars to the other side and discharge the captured screenings on one side. Huber would supply this screen as a variant of their standard RakeMax® multi-rake bar screen.

Figure 5-4
Alternative C Plan View (Huber RotaMax CF)

5.3 Alternative D: Two Overflow Screens with Screws

This alternative includes installing two overflow-type screens on both East and West walls of the easternmost screening channel. Similar to COPA® and ROMAG screens, overflow screens return the captured screenings to the influent channel, which needs to be carried over to the Screening Collection Channel by a portion of the influent flow. **Figure 5-5** shows the proposed arrangement of these new screens in plan view. The flow direction through the screen is typically from top to bottom. The semicylindrical perforated screen field is under the rotating screw equipped with soft brushes on the edge of the screw, which aid in screen field cleaning. Accordingly, these screens hang from the outer wall face at the top of the concrete walls. Both Huber ROTAMAT® RoK1 and SAVCO SAVI VSE700 can be made in 28-inch diameter and 28 feet long for this application. Huber ROTAMAT® RoK 2 is also a similar equipment with an opposite upward flow path due to the location of the semicylinder perforated plate screen on top of the screw. Accordingly, RoK 2 can be installed on the inner face of the concrete walls of the Screening Inlet Channel and stay entirely within the channel. Therefore, the structural modifications for this alternative are minimal.

Figure 5-5
Alternative D Plan View SAVECO SAVI VSE (top left) and Huber ROTAMAT® RoK1 (top right)

5.4 Other Alternatives

In addition to the main alternatives described above, a few other alternatives were considered, listed below. These alternatives are presented in this subsection as a group as they are considered secondary alternatives that are less promising than the first group and face challenges to meet the guiding principles of the project and improvement goals.

5.4.1 Alternative E: Multi-rake Bar Screen and Overflow Screen

This alternative is a combination of Alternative A, and Alternative D. One multi-rake bar screen on the south end of the Screening Inlet Channel captures screenings similar to Alternative A. However, to achieve a higher hydraulic capacity for this screening channel and especially during significant events, an upstream overflow screen would be installed on the south wall of the channel. Captured material with the overflow screen will be discharged back to the channel and recaptured again by the multi-rake bar screen. **Figure 5-6** shows the plan view of this alternative. Huber can supply both types of these screens. The structural modifications needed for this alternative are similar to Alternative A.

Figure 5-6
Alternative E Plan View (Huber)

5.4.2 Alternative F: Continuous Element Screens

This screening technology (sometimes referred to as belt, band, or escalator screens) consists of a continuous band of either perforated plate or bar screen media that rotates through the influent stream. The screen serves the dual purpose of removing debris from the waste stream and conveying it out of the channel to the operating floor for discharge. The debris is then usually removed from the screen by a water spray, sometimes in conjunction with a counter-rotating brush. There are two continuous element screen styles: perforated plate screens and bar screens. Five perforated plate panel constant element screens on the market in the U.S. are the Aqua Guard PF manufactured by Parkson, the Filterscreen manufactured by FSM (SAVECO), the Perforator® marketed by Headworks®, the Escamax manufactured by Huber, and the Aqua-Screen manufactured by Andritz. The most common continuous element bar or fine mesh screen on the U.S. market is the AquaGuard manufactured by Parkson.

Baby Creek SDF and Oakwood RTB have continuous element screens with 6-mm openings. Baby Creek screens are Escalator® from US Filter/Envirex (presently supplied by Veolia's John Meunier), and Oakwood screens are Andritz Aqua-Screen.

This type of screen can be installed in arrangements similar to multi-rake screens indicated in previous alternatives. The structural modifications needed for this alternative are similar to Alternative A. These are some advantages and disadvantages of continuous element screens:

- Advantages
 - With perforated plate or mesh elements, high screenings capture ratio can be achieved due to two-dimensional screening. Perforated plate varieties prevent thin objects from wedging into the screen or passing through a bar configuration.
 - Capability to lift large debris out of the flow
 - Medium-sized footprint due to recommended inclination angle (typically 60-75 degrees from horizontal, possibly more)
 - Typically no submerged bearings with manufacturers that use a guide rail at the channel bottom to support the submerged screen elements
 - Medium to low headroom required
- Disadvantages
 - Numerous moving components are subject to wear
 - High headloss because of the low percentage of open area and flow having to pass through the screen twice

- Wet screenings and a substantial amount of wash water are required
- Potential for perforated plate screen holes to plug with hair, stringy material, or grease
- The brush or spray water may not entirely remove the screened material. When this happens, the material removed on the upstream side of the unit is carried over and deposited in the downstream flow, partially reducing the capture of screenings
- Perforated plate screens are not recommended for directly screening combined sewage flow without protection from either a coarse bar screen or a pump station upstream of the screen

5.4.3 Alternative G: Replacing COPA® Screens with ROMAG Screens

In this alternative, COPA® screens of the most eastern channel will be replaced with ROMAG screens similar to the arrangement of existing screens in the westernmost channel. So, except for the improvements described for rehabilitating the existing ROMAG screens, it is expected that the replaced screens of the easternmost Channel will perform similarly to the other existing ROMAG screens. The structural modification for this alternative is limited to some height adjustment for the east and west walls of the Screen Inlet Channel and lowering the height of the ROMAG screens by 1-foot to meet the manufacturer's guidelines for maximum through bar, slot velocity of 5 ft/s as described in Section 4.1. After this improvement, considering a scenario when one of the channels equipped with ROMAG screens is out of service, three other remaining channels can screen the peak design flow of 950 cfs.

5.4.4 Alternative H: Facility Expansion and Major Structural Modifications

This final alternative is considered to provide the maximum flexibility to install a new screening technology that meets project requirements and follows the project's guiding principles without being bound by the existing structure and facility constraints. The available logical area for expanding the existing facility and providing the required space for a new screening channel is on the east side of the facility for a new parallel Screening Influent Channel. The north and south side of the facility do not have the proper room for expansion due to the existing in and out flow paths and also the location of the control building on the north side. The east side appears to have room for expansion contingent on the acquisition of the available vacant lots on that side and also the alleyway. **Figure 5-7** shows the plan view of the existing site, the vacant parcels acquired for a new driveway, and the potential land needed for expansion on the east side.

The construction of this alternative requires significant modifications to the existing structure and adds considerable area and structural component to the facility. The impacts to other systems, HVAC, lighting, and electrical improvements, are also significant. This alternative was not pursued further given the goal to accommodate the improvements for the present and future conditions within the limits of the existing footprint.

Figure 5-7
Alternative H Potential Land Acquisition Plan

5.4.5 Other Alternatives that Were Ruled Out

Other technologies like Single Rake Bar Screens, Stair Screens, Inclined Cylindrical Screens, Grinder/Auger Screens, and Center-flow Band Screens were also considered but ruled out due to their limitations of inapplicability to the existing project condition. The main criteria for ruling out each of these technologies are listed below:

- Single Rake Bar Screens: infrequent single raking mechanism cleaning cycle and the resulting screen blinding potential.
- Stair Screens: potential for damage from excessive amounts of grit. Grit material can become jammed between the lamella bars, causing excessive wear, jamming, and damage to the lamellas or motor
- Inclined Cylindrical Screens: placed in shallow channels with limited depth. Manual removal of large debris would be required and has a minimal flow rate per unit capacity.

- Grinder/Auger Screens: limitations similar to Inclined Cylindrical Screens
- Center-flow Band Screens: large solids may be retained in the drum and require manual removal; there are a limited number of installations of this technology in the U.S. It is not typically used for CSO applications or flows less than 150 cfs.

5.5 Pilot Screen Alternatives Evaluation Criteria

Multiple criteria were considered to evaluate the alternatives previously described in Section 5. These criteria include meeting key objectives of this task defined in the Contract, guiding principles provided by GLWA, and technical and construction feasibility.

The following criteria were considered for these evaluations:

- Meet the flow and head loss requirements: Consider if the alternative can convey the required flow to meet the total peak screening design capacity of the facility with one Screening Inlet Channel out of service without raising the water surface elevation beyond the existing emergency overflow of the ROMAG screens. Also consider if replicating the alternative for other screening channels (with equipment sized for the utilized channels) in future will meet the flow and head loss requirements.
- Effective capture of screenings: Meet the requirements of the NPDES permit considering that the receiving water shall contain no identifiable sanitary solids (floating or settleable) or deposits as a result of this discharge in unnatural quantities which are or may become injurious to any designated use.
- Comply with present version pertinent design standards:
 - Ten State Standards requirements, including screen redundancy, approach and slot velocities, etc.
 - Material and classification requirements, including corrosion resistance and NFPA 820 Class I Div. I area classification
- Effective conveyance of screenings to Toward Treatment Sewer: consider maintaining the present method of transferring screenings to Toward Treatment Sewer for deflection screens and not add a screenings handling operations task at the facility with the alternate screen technology. As part of this consider the flow constraints to TTS balanced with effective screenings conveyance
- Reduce the possibility of clogging and overtopping screens: operate in accordance with screen manufacturer's recommendations to minimize the number of times the screen is overtopped

- Reliable system components: Limiting the number of times that equipment is out of service or shuts down due to various system faults, communication loss, etc.
 - System ready on demand on an intermittent basis
 - Reduced number of single points of failure and having a reliable installation track record for similar existing applications
- Ease of construction: Consider the level of modifications to the existing system and structure including required access for installation. Also consider the required phasing of the project from pilot screen installation to whole facility rehabilitation and maintaining the screening capacity during these phases.
- Ease of operation and control: have simple control and operation to the extent possible with the capability to run in manual when needed. Reduced human capital needed for operation. Simple controls with reduced nuisance alarms and alarms that shut down the equipment. Minimized number of permissive to start equipment.
- Ease of access, cleaning, and maintenance: Have enough space for safe access, reduced human capital, and cost needed for maintenance. Fewer moving parts and more durable components that need maintenance.
- Redundancy: have sufficient redundant system components
- Manufacturer: combination factors including availability of multiple manufacturers, their U.S.-based and local services, their responsiveness, history, and reputation

6.0 Pilot Screen Alternatives Analysis

This section evaluates the alternatives using the criteria presented in Section 5.5. Two alternatives were not carried forward for further evaluation.

- Alternative F (continuous element screen), was not evaluated further due to its limitations meeting the required hydraulic capacity at the peak flow and its disadvantages in comparison with the multi-rake bar screen.
- Alternative H (facility expansion), was not considered further due to its costly, extensive, challenging structural modifications, and likely major system revisions to other systems including HVAC and electrical. In addition, this alternative would not be able to accommodate the improvement goals for the present and future conditions within the limits of the existing footprint with other alternatives.

The alternatives A, B, C, D, E, and G are included in **Table 6-1** and compared with respect to the major evaluation criteria listed in the Section 5.5. Based on the evaluation summarized in this table,

Alternative A, with one multi-rake bar screen on the south end of the Screen Inlet Channel, appears to be a viable alternative for the pilot screen.

The possibility of using this Alternative to meet the future Leib peak design flow (after the replacement of all screens) was also investigated. As shown in **Figure 6-1**, by implementing several structural modifications and repurposing the middle Screening Outlet Channels as Screening Inlet Channels, it will be possible to convey peak design flow with this alternative with one of the largest units out of service. Accordingly, this alternative is considered one of the viable options to be analyzed more from a life cycle cost perspective.

Table 6-1 Summary of Pilot Screen Alternative Analysis

Alternative	A	B	C	D	E	G
Description	One Regular Type Multi-Rake Bar Screen	Two Multi-rake bar Screens Perpendicular to the Flow Direction	One Center Flow Multi-Rake Bar Screen	Two Overflow Screen with Screw	a Multi-rake Bar Screen and an Overflow Screen	Replacing COPA® Screens with ROMAG Screens
Number of Screens	1	2	1	2	2	2
Additional Appurtenances	One Sluice Chute	Two Sluice Channels	One Sluice Channel	One Existing Gate	One Sluice Channel	One Existing Gate
Meeting the flow and head loss requirements	Can screen about 190 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Can handle the whole facility's peak demand in future extensive modification.	Can screen about 380 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Can handle the whole facility's peak demand in future moderate modification.	Can screen about 240 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Can handle the whole facility's peak demand in future extensive modification.	Can screen about 250 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Not capable of handling the whole facility's peak demand in future modification.	Can screen about 290 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Not capable of handling the whole facility's peak demand in future modification.	Can screen about 390 cfs in this installation and in combination with other existing screens, will meet the design peak flow. Can handle the whole facility's peak demand in future, with limited modifications.
Effective capturing of screenings	One-dimensional 6-mm screen	One-dimensional 6-mm screen	One-dimensional 6-mm screen	Two-dimensional 6-mm screen	Combination of one and two-dimensional 6-mm screens	One-dimensional 4-mm screen
Effective transfer of screenings to Toward Treatment Sewer	Relatively short sluicing with limited wash water use	Moderate-length sluicing with moderate wash water use	Moderate-length sluicing with limited wash water use	Challenging deflection of screenings away from the screen field against the water flow. Considerable flow to TTS	Combination of deflection screening and sluicing. Relatively short sluicing with limited wash water	Relies on deflection of screenings away from the face of the screen against the water flow. Considerable side flow needs
Reducing the possibility of clogging and overtopping screens	Less prone to clogging or overloading	Less prone to clogging or overloading	Some potential for cleaning mechanism to push material around without effective cleaning	Moderate to the high potential of clogging or overloading screen	Combination of deflection screen and multi-rake bar screen Moderate to the high potential of clogging or overloading screen for deflection screen	Above average potential of clogging or overloading screen, if facility operated without required side flow.

Table 6-1 Summary of Pilot Screen Alternative Analysis (continued)

Alternative	A	B	C	D	E	G
Reliable system components	Reliable type of equipment with many examples of a similar installation	Reliable equipment installed in an uncommon arrangement	Newer version of reliable multi-rake bar screens with limited installation records	Limited installation, especially within the expected range of flow	Combination of a more and less reliable and common type of equipment	Some installation records but less common and reliable than other types (e.g., multi-rake bar screen)
Ease of construction	Limited structural modification with limited challenges for rigging and assembly	Challenging structural modification with some conflicts and difficult downstream level control during the pilot phase. Moderate challenges for rigging and assembly	Moderate structural modification with limited challenges for rigging and assembly	Very limited structural modification with minimal challenges for rigging and assembly	Combination of both types of screen modification needs and more complex rigging and assembly	Limited structural modification with minimal challenges for rigging and assembly
Ease of operation and control	Relatively easy to control and operation in auto and manual modes	Relatively easy to control and operation in auto and manual modes	Relatively easy to control and operation in auto and manual modes	Relatively easy to control and operation in auto and manual modes	More complicated control and operation in auto and manual modes due to a combination of two pieces of different equipment	Relatively easy to control and operation in auto and manual modes
Ease of access and cleaning	Moderately accessible equipment	Tighter installation arrangement and limited space, and the harder-to-access area between screens	Harder to access and clean areas downstream of the screen	Harder to clean and access perforated plates under screws, multiple pieces of equipment	Harder to clean and access perforated plates under screws. Multiple pieces of dissimilar equipment	Moderately accessible
Ease of maintenance	Limited maintenance needs of moving components on the lower elevations	Limited maintenance needs of moving components on the lower elevations. Multiple pieces of equipment	Lack of moving components at the bottom of the channel	Some challenges to access, and required maintenance of bearing, screen brushes, etc. Multiple pieces of equipment	Some challenges to access and require maintenance of bearings, screen brushes, etc. Multiple pieces of dissimilar equipment	Hydraulic power pack, cylinder, and line maintenance
Redundancy	One piece of equipment	two pieces of equipment with good hydraulic capacity	One piece of equipment	Two pieces of equipment with moderate hydraulic capacity	One piece of equipment effectively separates the screenings from the flow	Two pieces of equipment with good hydraulic capacity
Manufacturer	Three reputable manufacturers with good responsiveness and local representation	One reputable on-board manufacturer with uncommon installation arrangement with good responsiveness and local representation	One reputable manufacturer with moderate responsiveness and local representation	Only two manufacturers with moderate responsiveness and local representation	Only one manufacturer for both screens with moderate responsiveness and local representation	Only one manufacturer with moderate responsiveness and local representation

Figure 6-1
Alternative A Future Expansion Plan (Magenta bar screens) To Accommodate Future Peak Design Flow

One of the significant structural changes to accommodate the installation of future wider multi-rake bar screens is related to providing access openings through the roof of the screening chamber. To complete this, the entire existing soil fill above the slab at elevation 131.00 would be removed first. After soil is removed, a new concrete wall would be cast in line with the end of the existing channels. The new concrete wall will support the precast concrete beam to be installed, as described below. A new opening of approximately 16 feet x 10 feet would then be cut in the slab at elevation 131.00. Finally, a new precast concrete beam and removable slabs similar to the existing would be installed at elevation 139.00. Care would need to be taken during this installation to avoid damaging existing beams or columns that are to remain. **Figure 6-2** shows the general extent of these modifications at elevations 131ft on the left and 139 ft on the right.

Figure 6-2
Major Structural Modification at Elevation 131 ft (left) and 139 ft (right) to Accommodate Access Hatched Needed to Install Wider Multi-rake Bar Screen in Future

Alternative B, with two multi-rake bar screens, installed perpendicular to the flow direction, had promising hydraulic capacity. However, it seems to be a less common installation, and there was only one major manufacturer who had experience with this type of installation. In addition, considering its challenging structural modifications to control the water depth downstream of the pilot screen and limited space around screens, the potential of structural conflict resulted in ruling out this alternative from a technical and feasibility perspective.

Alternative C with center flow multi-rake bar screen was only offered by one manufacturer. Its limited capacity to pass the facility's peak design flow in the future (after the replacement of all screens) was a major challenge. Also, the lack of a reliable installation track record in similar CSO projects resulted in ruling out this alternative on a technical basis.

Alternative D, with two overflow screens with screws, did not have a long track record of installation in the required flow capacity range required for Leib in the United States (U.S.). It appeared to be an unproven technology for this application and was not capable of handling the future Leib peak flow rate (after replacing all existing screens). Accordingly, this alternative also was not considered for further analysis on a technical basis.

Alternative E, as a combination of Alternative A and D, could improve the flow capacity during the pilot phase. However, it could not accommodate the future peak capacity (after replacing all existing screens). In addition, the complexity of the system with multiple pieces of different types of

screens and the other challenges of Alternative D was a negative. Accordingly, this alternative was not considered for further life cycle cost analysis on technical basis.

Alternative G, including replacing the COPA® screens with ROMAG screens in two channels, was requested to be investigated by GLWA. Considering its hydraulic capacity and consistency of the equipment with what is already installed in this facility, and that it has been in use for two decades, making it a viable alternative, if the facility is operated with at least the minimum required side flow. Also, limited structural modification and potential to improve its performance by using updated controls and improved operation procedures transformed it as an appealing alternative which is considered for further LCC analysis.

Similar to Alternative A, the possibility of using Alternative G to meet the future Leib peak design flow (after the replacement of all screens) was also investigated. By implementing limited structural modifications, it will be possible to screen flows higher than peak design flow with this alternative with one channel out of service. Accordingly, this alternative is considered another viable option to be analyzed more from a life cycle cost perspective.

Based on the result of this technical analysis and comparison, Alternatives A and G, were selected for further economic comparison via life cycle cost analysis as discussed in Section 7.

7.0 Life Cycle Cost Analysis

The approach and assumption used for Life Cycle Cost Analysis (LCCA) are listed in this section.

7.1 Approach

Comparative cost estimates intended to represent order-of-magnitude estimates for equipment capital and O&M costs. This LCCA intended for planning purposes and comparing alternatives and does not serve as an Opinion of Probable Construction Cost (OPCC). Accordingly, common improvement or modifications items between the alternative might not be included in the analysis. Following bullet points shows the list of general parameters that were used for this LCCA:

- Lifecycle period: 20 years
- Baseline year: 2023, Bringing future cost back to present year for present value comparison
- End of Construction and Start of 20-year Life Cycle: February 2029 (per present schedule)
- Midpoint of Construction: May 2027 (per present schedule). Approximately 51 months (4.25 years) from February 2023
- Discount rate of 4% is applied to the future costs of purchase, installation, and commissioning of equipment, energy costs, maintenance and replacement costs, and salvage value when calculating the total present value of each alternative in 2023
- Summary values are rounded to nearest \$5,000

7.2 Initial Purchase, Installation and Structural Modifications

Initial purchase cost was based on budgetary costs estimates for major equipment and components. Supporting component purchase costs is estimated, as needed to distinguish between alternatives. Supporting elements are estimated by approximate percentage of primary equipment cost. For both alternatives instrumentation and control are estimated as 5% of the component purchase cost. Electrical cost of Alternative A is estimate as 15% of the component purchase cost due to more extended electrical components inside the classified area. This estimate is changed to 10% of the component purchase cost for Alternative G, as its components in the classified area are hydraulically powered.

For both alternatives, installation and commissioning are estimated as 30% of the equipment purchase cost. Structural modifications are estimated based on calculated quantities and CDM Smith's OPCC for these items. Contractor costs, including general conditions, permits, insurance, bonds, overhead and profit, and 30% contingency is added to the purchase, installation, commissioning costs and structural modifications as an overall percentage of 75%.

Escalation rate of 6% is applied to the initial purchase costs for equipment to escalate it from present to the year of purchase/installation, which is assumed to be 2027. CDM Constructors Inc. (CCI) estimates are using 7% escalation for the next 2 years, the following 2 years are at 5% escalation, and then later years would have a lower escalation rate. Accordingly, it is recommended for the approximate 4 years of escalation needed from present to midpoint of construction apply an average escalation rate of 6%. The same rate is applied to the installation and commissioning costs to account for escalation of labor rates.

For Alternative A, these items were considered:

- Phase 1 (starting 2027):
 - Demolition of COPA® screens in the easternmost channel and its Screening Channel Gate
 - Installing one new narrower multi-rake bar screens in the easternmost screening inlet channel
 - Rehabilitation of existing ROMAG & COPA® screens in other remaining channels are not considered in this LCCA as these are common costs to both Alternatives A & G (Phase 1). Also, during Phase 1, only the O&M cost associated with the easternmost channel screens is included, as the O&M cost of other channels is a common cost to both Alternatives A & G.
 - Minor structural modifications for channel and flow path and for installing new screen
- Phase 2 (starting 2037):
 - Demolition of all remaining ROMAG and COPA® screens and Screening Channel Gates

- Installing two new narrower multi-rake bar screens in the westernmost and easternmost screening inlet channels
- Installing three wider multi-rake bar screens in three middle channels, including engineering cost
- Major structural modifications for channels and flow paths and for installing new screens

For Alternative G, these items were considered:

- Phase 1 (starting 2027):
 - Demolition of COPA® screens in the easternmost channel
 - Installing two new ROMAG screens instead of COPA® screens
 - Minor structural modifications for installing new screens
 - Rehabilitation of existing ROMAG & COPA® screens in other remaining channels are not considered in this LCCA as these are common costs to both Alternatives A & G (Phase 1). Also, during Phase 1, only the O&M cost associated with the easternmost channel screens is included, as the O&M cost of other channels is a common cost to both Alternatives A & G.
- Phase 2 (starting 2037):
 - Demolition the remaining COPA® screens
 - Installing two new ROMAG screens to replace COPA® screens
 - Minor structural modifications for installing new screens

Lowering the existing ROMAG screens about 1-foot and replacing screen discharge weir plates are common activities for Phase 1 of Alternative A & Alternative G are not included in LCCA.

7.3 Operation, Energy, and Maintenance

Alternatives analyses for systems/equipment with significant energy requirements or significant, quantifiable differences in energy requirements includes energy cost comparisons in the LCCA. However, in this case, the relative low energy usage of screens, in addition to the low frequency of screen activation in this facility resulted in an insignificant effect of energy cost on LCCA. Total power consumption of all screens of Alternative A is 21 horsepower. This number for Alternative G is 40 horsepower. This facility screens are being activated in average about three times per year with total duration of about 24 hours per year. Considering increasing the events two times higher in future after adding Meldrum St. connection, the lifecycle energy cost difference between two alternatives is less than a couple thousand dollars.

Elements of routine maintenance and mid-lifecycle replacement needs are focused on areas of difference between alternatives.

Escalation rate of 3.5% is applied to routine maintenance and mid-lifecycle replacement materials and labor. The escalation rate used for maintenance is based on the historical average escalation rate due to the number of years into the future that these costs are projected.

7.4 Decommissioning/Salvage

Decommissioning/Salvage value of 10% of the original equipment purchase cost (before sales tax) is assumed for major equipment, and then escalated to the end of the 20-year analysis period using a 3.5% annual escalation rate (consistent with maintenance escalation rate). Salvage value is used as a negative value in the LCCA because it is an income as compared to the other values included in the analysis, which are costs.

7.5 Life Cycle Cost Analysis Results

Table 7-1 shows the summary of LCCA analysis for both phases of Alternatives A and G. Accordingly, it is clear that Alternative G with fewer new screens installed and less structural modifications, is about \$3.96 million less expensive than Alternative A.

Table 7-1 Summary of Life Cycle Cost Analysis

Alternative	Capital Costs (Year 2027 for Phase 1 & Year 2037 for Phase 2)			20-Year Net Present Value of Capital Costs	O&M Cost Breakdown		20-Year Net Present Value of O&M Costs	Salvage Net Present Value	20-Year Net Present Value
	Initial Capital Cost	Installation, Commissioning & Startup	Total Construction Cost		Electricity	Maintenance			
A (Phase 1)	\$745,000	\$1,105,000	\$1,850,000	\$1,580,000	\$0	\$30,000	\$30,000	\$55,000	\$1,560,000
A (Phase 2)	\$6,355,000	\$10,215,000	\$17,475,000	\$10,090,000	\$0	\$580,000	\$580,000	\$315,000	\$10,360,000
A (both phases)				\$11,670,000			\$610,000	\$370,000	\$11,920,000
G (Phase 1)	\$1,600,000	\$4,665,000	\$4,020,000	\$3,435,000	\$0	\$30,000	\$30,000	\$0	\$3,470,000
G (Phase 2)	\$2,865,000	\$4,845,000	\$7,225,000	\$4,170,000	\$0	\$615,000	\$615,000	\$300,000	\$4,485,000
G (both phases)				\$7,605,000			\$645,000	\$300,000	\$7,955,000

8.0 Summary and Recommendations

The evaluation of the existing screening system consisted of a multi-faceted approach, including reviewing existing records or original design and construction, subsequent modifications, operating data and process video recordings, site visits, interviews and meetings with operations staff, and screening sampling efforts (sampling not yet performed at time of this writing).

After this evaluation, several improvements are recommended to enhance system reliability and improve debris removal to allow the screens to function optimally leading to reduction of the number of times the screen is overtopped. The improvements cover potential modifications to the remaining ROMAG & COPA® screens in conjunction with control and operational changes. In summary, it is suggested that ROMAG hydraulic power units and control and instruments for screen cleaning mechanisms be replaced with the more up-to-date design. No changes are recommended for the COPA® screen due to a lack of improvement in its design over the last three decades. However, due to the age of the equipment, replacement of its power pack and combs is recommended. To improve control and operation, the primary recommendation is to run the equipment as much as possible on auto and allow 10% of the influent to be conveyed to Toward Treatment Sewer to reduce the accumulation of screenings upstream of these diversion-type screens.

In addition to the proposed improvements to the existing equipment and their operation, several alternatives to replace the COPA® screen of one of the Screening Inlet Channels with another screen technology were presented and analyzed. Based on the analysis of Alternatives A to H and considering their technical pros and cons in conjunction with project guiding principles, Alternative A and Alternative G were recommended for further evaluation and life cycle cost analysis. Alternative A includes installation of a multi-rake bar screen in one Screening Inlet Channel and discharging the screenings to the Screening Collection Channel. An expansion of this alternative for future consideration is also summarized in this TM. This expansion will allow replacement of all remaining ROMAG and COPA screens with similar multi-rake bar screens to meet the peak screening design flow of 950 cfs while one of the screening channel is out of operation. This expansion will modify some flow paths through the Screening Inlet and Outlet Channels to convert the three existing middle Screening Outlet Channels to future Inlet Channels and two existing middle Screening Inlet Channels to future Outlet Channels.

In addition to Alternative A, Alternative G, including replacing the COPA® screens with ROMAG screens in one channel, was requested to be investigated by GLWA. Advantages to Alternative G include limited structural modification, ROMAG screen's hydraulic capacity, and consistency of the equipment with what is already installed in this facility. The consistency of the screen technology, not only has the advantage of operational familiarity, but also commonality of spare parts and understanding of maintenance needs. The life cycle cost analysis showed considerable economic advantage of Alternative G over A. The main driver for this considerable cost difference was limited structural modifications and capability of maintaining the existing ROMAG screens in service after some rehabilitation, including replacement of hydraulic power units and control and instruments

for screen cleaning mechanisms, in Alternative G. Another advantage of Alternative G over A include screenings capture capability with the smaller opening size of ROMAG screens (4-mm) in comparison to opening size with multi-rake bar screens (6-mm).

With the manufacturer recommended updates to the power pack, control panel, and new control logic, and operation of the facility in accordance with manufacturer recommendations for screen operation and providing the required side flow minimum of 10% through proper gate operation, Alternate G is technically feasible. Hydraulic analysis was completed to confirm that it is technically feasible for the system to produce the minimum 10% side flow within an acceptable headloss. Therefore, based on several advantages and lower cost, Alternative G, all ROMAG screens, is the recommended alternative to meet GLWA's goals and associated guiding principles for this project improvement item.

9.0 Next Steps

This section lists the items that require advancement/further development as the design process advances. After the final selection of one of the proposed alternatives by GLWA the following items will need to be addressed:

- Define the detailed structural modifications and evaluate the potential conflicts and modifications required to resolve them to coordinate the selected alternative with associated structural modifications.
- Determine extent of modifications to screen inlet channel concrete floor slope to be compatible with lowering of ROMAG screens to avoid conflict between sloped concrete and lowered screen equipment.
- Develop a detailed plan for the improvement implementation by considering how equipment would enter the process space and installation options available for large pieces of equipment coupled with associated constraints for maintenance of operation during construction.
- Refine the hydraulic grade line development for the selected alternative.
- Finalize the material and coating selection for various components of the selected alternative.
- Develop control strategies and required instruments for the selected alternative, including the local control station at the operation floor.
- All new and/or modified process mechanical loads will be coordinated with electrical to verify available power system capacity, available voltages, and the location of electrical gear required for each piece of equipment.
- Expand the design criteria table for the selected alternative to include approach velocities, channel levels, and speed of cleaning along with estimates of solid loading and mass removal rates.

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Steve Fehniger and Julie Aichler, CDM Smith
Paul Witt, PCI*

Date: June 1, 2023

*Subject: TM-15 Storm and Sanitary Pump Operational Strategies Improvement Evaluation
(OKW-PUMP-1A) Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The problem statements incorporated and addressed in this technical memorandum (TM) include improvements to the operational strategies for the storm pumps, sanitary pumps and wet well level sensor selection. These improvements were guided by review of operating data, ride-along observations and discussions, determination of revised minimum storm wet well level for each storm pump size, Allowable Operating Region (AOR) and Preferred Operating Region (POR) provided by pump manufacturers, evaluation of how to maintain pump operation within their respective AOR, review of present Auto mode operational strategy programming and review of past studies.

Recommendations

Storm pump operational strategy: Improve operational strategy as described conceptually in Section 4.

Sanitary pump operational strategy: Improve operational strategy as described conceptually in Section 4.

Wet well level sensor selection operational strategy: Improve operational strategy as described conceptually in Section 3.

The evaluations performed to determine the above recommendations as follows:

- Review of operating data: for key parameters determined patterns which guided how to improve the operational strategies. Refer to Section 3.1.

- Ride-along observations and discussions: enhanced understanding of the present operational practices including where may consider changes to extend service life and optimize operation. Refer to Section 3.2.
- Determination of revised minimum storm wet well level for each storm pump size: Physical model study findings combined with net positive suction head (NPSH) margin evaluation and check of motor loading resulted in lower lead pump shut off levels, 62.5 ft for large pumps and 61 ft for small pumps. Refer to Section 3.3.
- AOR and POR provided by pump manufacturers: Xylem Flygt AC Custom pump and Xylem Flygt provided performance curves with application specific AOR and POR limits. Refer to Sections 2.1.1 and 2.2.1.
- Evaluation of how to maintain pump operation within their respective AOR limits: The manufacturer provided AOR limits were utilized in the overlay of system curve envelope with performance curve to determine where and over what speed range the pumps could be operated for these applications. Speed range restrictions which differ from present practice are required to maintain operation within the AOR over full range of operating conditions. Refer to Section 3.4.
- Review of present Auto mode operational strategy programming: The Design Team tabulated and reviewed the present Auto mode operational strategy programming to assess how it relates to the common manual operation of the storm pumps with behind-the-scenes control logic on some elements and combination of manual and automatic operation of the sanitary pumps relative to the findings from our evaluations. Refer to Sections 2.1.3 and 2.2.3.
 - An area of concern was identified related to sanitary pump auto shutoff level and the associated level sensor selection programming due to discrepancies between the radar and ultrasonic level readings. Refer to Section 2.2.3.4.1.
- Review of past studies: The past studies summarized in the CS-299 report (included as an appendix to the Conceptual Design Report) and the Brown & Caldwell TM findings and recommendations were reviewed to determine how/if our evaluations may need to be modified based on the earlier work. Overall, our path forward tended to differ by varying extents as compared to those recommendations. Refer to Section 3.6.

1.0 Introduction and Purpose

TM-15 is focused on evaluation of improvements to the existing storm pumping system and sanitary pumping system operational strategies. The goals of evaluation center around several project guiding principles with attention to maximizing performance efficiency (optimizing), reliability, and service life while minimizing downtime and maintenance requirements to the extent feasible.

The TM was configured to first cover the storm pumping system and then the sanitary pumping system when the topic covered is not common to both applications.

The evaluation included consideration of the following:

- Review of operating data
- Operational difficulties understood from operations ride-along visits.
- Reduction of storm pump minimum operating level from physical model study to maximize pump run time for each pump cycle while operating within AOR.
- Constraints on pump operation to maintain operation within the AOR while maximizing service life of storm and sanitary pumps.
- Maintain the storm pump historical maximum operating level (El 78.00) to match the freeboard present to minimize potential for basement backups in the Oakwood subdistrict.
- Consideration of CS-299 report and Brown & Caldwell TM findings focused on the storm and sanitary pump systems.

This TM answered key storm pumping system-related questions linked to the improvement of the storm and sanitary pump operational strategies. The questions answered included the following:

- How low can the storm wet well be operated for each pump size?
- What is the AOR and POR of each pump size/model?
- What speed range will be feasible to maintain operation within the AOR over the system curve envelope?
- What other constraints will impact the proposed revisions to the operational strategies

For additional storm pump system topics evaluated as part of the project, refer to the following technical memoranda/reports developed on the topics of storm wet well pump intake conditions (storm pump station physical hydraulic model study report included in Appendix A), and storm wet well flushing system improvements (TM-22) for coverage of those topics.

2.0 Existing System(s) Description (and/or Conditions)

The existing Oakwood storm pump station is configured with a split modified trench wet well as the intake for the storm pumps. Downstream of each trench is a solids handling type wet well equipped with submersible sanitary (SN) pumps as shown in **Figure 2-1**. The wet wells are connected only at the upstream junction chamber which is located near the southern limit of the facility site.

Figure 2-1
Oakwood Storm and Sanitary Wet Well Configuration (PC-755 Record Drawing D-04-08-405)

2.1 Storm Pumping System

The Oakwood storm pump system is comprised of eight vertical mixed flow storm pumps positioned within the two wet wells with “small” variable speed-controlled pumps at the upstream end of each wet well followed by “large” vertical mixed flow pumps. The pumping units were all furnished and installed as part of the original construction. The pumps were manufactured by ITT Flygt (now Xylem Flygt AC-Custom Pump) and the motors were manufactured by Hyundai Ideal (now Ideal Electric). The pump station has a firm pumping capacity of 1675 cfs (1,100 MGD) at the design total head with one of the large pumps off-line.

No major modifications have been made to the pumping units since placed into service in 2012. One pump (ST-5) was rehabilitated by Kennedy Industries in 2022.

Pump details are included in **Table 2-1**.

Table 2-1 Storm Pumping Units Summary

Pump Nos.	Pump Description	Design Point Total Head, ft	Design Point Flow Rate, cfs (MGD)	Motor Full Speed, rpm	Motor HP	VFD speed-controlled, Y/N	Present Speed Range, % speed	Discharge Size, in.
ST-1 and 2	Small Pump	48	150 (97)	594	1500	Y	75 - 100	54
ST-3, 4, 7 and 8	Large Pump	48	275 (178)	446	2000	N	NA	72
ST-5 and 6	Large Pump	48	275 (178)	446	2000	Y	75 - 100	72

2.1.1 Storm Pump Performance Curves

The small (WCA 66 x 54) and large (WCA 88 x 72) storm pump performance curves shown in **Figures 2-2** and **2-3** were furnished by Xylem Flygt AC Custom Pump. The POR range from 85 to 115 percent of BEP flow rate is aligned with the guidance in latest edition of ANSI/HI 9.6.3

Operating Regions guideline for the specific speed (7300). The AOR limits are determined by the pump manufacturer in accordance with ANSI/HI 9.6.3. As expected, the AOR left limit is set to avoid the unstable portion of the curve (flat portion).

Figure 2-3
Large Storm Pump Factory Test Performance Curve, courtesy of Xylem Flygt AC Custom Pump

2.1.2 Present Storm Pump Station Operations

The storm pump station is normally operated manually from the Ovation workstation in the pump station control room. The station is commonly left in auto mode when the facility is not staffed to facilitate system operation during a wet weather event as triggered by wet well level setpoints. On average, the station operates about 25 times per year (significantly more than on average 11 activations of the retention treatment basin. This operational frequency was based on review of downstream equipment systems which are required to be running before any storm pump will start (screenings conveyor data utilized) as determined through review of operational data from September 2019 – November 2022, excluding conveyor starts for post-event cleaning.

Present wet well level-based pump setpoints (Detroit datum):

- Lead pump start: 73 ft
- Lag pump start: 76 ft
- Maximum level: 78 ft
- Last pump in operation stop: 65 ft

Based on observations and discussions with operations staff as part of operations ride-along site visits, the selection of the first pump to start is an operator preference and can be a small pump or large pump (constant or variable frequency drive [VFD]). This decision is guided in part by desire to distribute the runtime between the storm pumps. In addition, some operators favor starting an event with a large pump as they feel the ability to dose a high concentration of sodium hypochlorite (hypo) at beginning is greater with the corresponding larger metering pump than the small pumps. Most events require only one storm pump to operate at a time with fill/draw approach with a resultant varied number of pump operation cycles per event.

The speed of the VFD speed-controlled pumps is automatically controlled “behind the scenes” via Ovation programming as the operations staff do not modify the VFD speed. Operators indicated the speed ramps up when the wet well level increases. For the events observed, these pumps remained at minimum speed as the flow rate did not continue to rise after the pump was turned on.

The subsequent pumps turned on is an operator decision with consideration of not starting a pump which has recently been shut down to allow motor to cool down.

2.1.3 Present Storm Pump System Ovation Control Logic for Automatic Operation

The present Ovation control logic is provided to aid in understanding of how storm pumps would be controlled if in Auto mode. However, the station is typically manually controlled when staffed such that the following logic application is limited by operational practices.

The following is a summary of the storm pump automatic operation sequence based on review of the presently programmed Ovation Control Logic. This scenario assumes that all storm pumps are operational and that all storm pumps are in Auto mode.

Prior to a storm event, the operator selects the Storm Pump (ST) sequence. The sequence is shown on a selection screen in Ovation as shown in **Figure 2-4**. The following sequence is commonly applied: ST1, ST2, ST5, ST6, ST3, ST4, ST7, ST8 (VFD speed-controlled pumps operate before the constant speed pumps). The target level to maintain in the wet well is 76 ft. As noted previously, the decision regarding lead pump selection is guided in part by desire to distribute the runtime between the storm pumps.

maintain the target level of 76 ft.

than 60 seconds, Ovation will start the next storm pump in the sequence.

together to maintain the wet well target setpoint.

speed to maintain the wet well target setpoint.

well level is 1.5 ft above the target setpoint for more than 60 seconds, Ovation will start the next

storm pump in the sequence. The fourth pump will run at minimum speed for 75 seconds. Then the pump will ramp up and the four operating pumps will slow down to match speeds and modulate speed to maintain the wet well target setpoint.

If the wet well continues to rise and the four running pumps are at maximum speed and the wet well level is 1.5 feet above the target setpoint for more than 60 seconds, Ovation will start the next storm pump in the sequence.

Typically, the remaining pumps in the sequence are constant speed pumps. The constant speed storm pumps are programmed internally (not through Ovation) to ramp up over a range of 0-180 seconds, with an initial setting of 75 seconds to allow discharge piping to fill up as the pump speed is increasing to full speed. The VFD speed-controlled pumps will continue to modulate to maintain the wet well target setpoint while the constant speed pump runs at full speed.

If the wet well continues to rise and the five running pumps are at maximum speed and the wet well level is 1.5 ft above the target setpoint for more than 60 seconds, Ovation will start the next storm pump in the sequence. The VFD speed-controlled pumps will continue to modulate to maintain the wet well target setpoint while the constant speed pumps will run at full speed. This sequence will continue until seven pumps are operating or the wet well level begins to fall.

As the wet well level begins to fall, the pumps will shut down in reverse order. As stated before, the VFD speed-controlled pumps will continue to modulate to maintain the wet well target setpoint while the constant speed pumps will run at full speed. If the wet well continues to fall and the four VFD speed-controlled pumps are running at minimum speed and the wet well level is 1.5 ft below the target setpoint for more than 60 seconds, Ovation will stop the last storm pump that was started in the sequence. The VFD speed-controlled pumps will continue to modulate to maintain the wet well target setpoint while the remaining constant speed pumps will run at full speed. If the wet well continues to fall and the four VFD speed-controlled pumps are running at minimum speed and the wet well level is 1.5 ft below the target setpoint for more than 60 seconds, Ovation will stop the next storm pump that was started in the sequence. This sequence continues with each pump turning off in the reverse order that they turned on until the last VFD speed-controlled pump is operating.

If the wet well continues to fall, the final VFD speed-controlled pump will continue to run until the level falls below 65 ft for 60 seconds. It should be noted that the original level to shut down the last pump was 71 ft. This value has been changed since the initial programming.

2.1.4 Present Storm Pumping Unit Vibration and Temperature Monitoring

The Ovation system monitors each storm pumping unit's vibration and temperature sensors.

2.1.4.1 Vibration Monitoring

The vibration sensors cause an alarm for any of the pumping units if a sensor value exceeds 0.85 in/s (documentation does not indicate in/sec RMS or peak).

The Multilin motor protection device for a representative pump was reviewed as well to check if a vibration trip was configured and set to On. The investigation identified that vibration trip value was configured but was set to Off. The configuration setting to Off for the variable speed-controlled pumps may have been set due to high vibration sourced tripping of the pumps with the operation commonly including the unstable portion of the curve and/or operation far left of AOR left limit. Both operating conditions lead to elevated vibration amplitudes. However, the pump system requires pumps to maintain levels to meet the needs of the system which cannot occur if shutting down on high vibration.

2.1.4.2 Temperature Monitoring

The temperature sensor monitoring by Ovation includes set points for alarm and trip temperatures. **Table 2-2** provides the alarm and trip temperatures for the storm pumps. Note that the motor lower bearing set points were 10 degrees Celsius higher for small pumps than the large pumps, but all other settings were the same for all pumping units.

Table 2-2 Storm Pump Temperature Set Points

Sensor location	Alarm	Trip
Motor Stator	120 °C	NA
Motor Upper Bearing	80 °C	85 °C
Motor Lower Bearing (Large ST/Small ST)	80/90 °C	85/95 °C
Motor Thrust Bearing	80 °C	85 °C
Pump Upper Bearing	65 °C	71 °C

2.2 Sanitary Pumping System

The Oakwood sanitary pump system is comprised of four vertical, submersible, solids handling pumps (two in each wet well). Sanitary pumps SN-2 and SN-4 are located in the East Sanitary Pump wet well. Sanitary Pumps SN-1 and SN-3 are located in the West Sanitary Pump wet well. The pumping units were originally wet-pit submersible Vaughan chopper pumps which have been replaced with Flygt N-series submersible solids handling pumps (model NP3315.095 MT FM) with 407 mm diameter impeller. The pump station has a firm pumping capacity of approximately 22 cfs (14.2 MGD) based on the overlay plot-based evaluation covered in Section 3 with one pump off-line.

Each on-line sanitary pump operates off level control set points as described below in greater detail. The pumps convey sanitary wastewater through a 14-inch discharge pipe. The 14-inch discharge pipes from each of pump combine into one 20-inch Sanitary Force Main within the sanitary pump discharge pipe vault located in the Sanitary Pump Room. From the sanitary pump discharge pipe vault, the pumped wastewater flows into its associated meter vault. The meter vault contains a magmeter, which measures the sanitary pump flow rate and totalized volume. The flow signal is sent from the magmeter to the Sanitary Pump VFD Control Cabinet and to the Ovation Control Screen where the flow volume is displayed and the signal used to control the speed of the pump.

2.2.1 Sanitary Pump Performance Curve

The Flygt NP3315 sanitary pump performance curve shown in **Figure 2-5** was furnished by Xylem Flygt through their local representative, Kennedy Industries. A submittal curve for this model and impeller trim was provided since no factory performance testing was performed on the sanitary pumps. The POR range from 70 to 120 percent of the best efficiency point (BEP) flow rate is aligned with the guidance in ANSI/HI 9.6.3 Operating Regions guideline in the specific speed range of this unit. The AOR limits are determined by the pump manufacturer in accordance with ANSI/HI 9.6.3. The AOR right limit at 125% of BEP flow rate was questioned in discussion with Xylem Flygt technical specialists. Xylem Flygt identified the right limit as required for the application based on their experience and added not driven by a perceived NPSH margin limitation.

Figure 2-5
 Sanitary Pump Submittal Performance Curve, courtesy of Xylem Flygt

2.2.2 Present Sanitary Pump Station Operations

The sanitary pump station is normally operated in Auto mode by the Ovation programmed logic. At times, operators choose to control the pump station manually from the Ovation workstation in the pump station control room. The system is left in Auto mode when facility is not staffed to facilitate continuous system operation.

The sanitary pump system operates continuously to match the influent flow to within the hydraulic capacity of the pumps except when turned off during a wet weather event. The past practice to operate one pump, including pump cycling, during wet weather events to keep the pumps from being buried in grit has not been utilized since an earlier study recommended termination of this operating practice (approximately 2019). This has not resulted in burying sanitary pumps in grit based on operations staff input.

When operated in Auto mode a target wet well elevation (operator selectable) is the focus of the level-based control system. The manual operation of the facility is typically within similar wet well level operating range in dry weather conditions.

Present wet well level-based pump setpoints (Detroit datum):

- Lead pump start: 44.5 ft
- Target level: 45 to 46 ft (operator selectable; automatically increased by 1-ft if three pumps in operation)
- Lag pump start: 1.5 ft above Target level
- Third pump start: 47.5 ft
- Last pump in operation stop: 41 to 42 ft (operator selectable)
- Pumps turned off due to anticipated wet weather event: 62-67 ft.

Based on observations and discussions with operations staff as part of operations ride-along visits, the selection of which wet well to operate in dry weather is an operator preference. This decision is guided in part by desire to distribute the runtime between the pumps. In addition, the differential head across the sanitary bar screen may impact which wet well to operate along with which pumps are out of service. Operations staff noted that dry weather conditions typically only require one sanitary pump in operation.

The speed of the VFD is automatically controlled “behind the scenes” via Ovation programmed logic as the operations staff do not modify the VFD speed. The speed is varied as described in the next section with the range of speeds between 1775 and 881 rpm.

2.2.3 Present Sanitary Pump System Ovation Control Logic for Automatic Operation

The present Ovation control logic is provided to aid in understanding of how sanitary pumps are controlled when in Auto mode. However, this pumping system is typically manually controlled when approaching storm pump operation such that the following logic application is limited by operational practices.

2.2.3.1 Background

There are two sanitary isolation pinch valves (SG-9 and SG-10) which direct flow into their respective wet wells. SG-9 is connected to the West Wet Well. SG-10 is connected to the East Wet Well. In “normal operation,” the operator chooses which wet well will be the initial wet well for control. The operator can select East or West by clicking the selected button on a pop-up. Assuming the pinch valves are in Auto, selecting West will open SG-9 and close SG-10. Selecting East will close SG-9 and open SG-10.

Each of the two sanitary wet wells were originally provided with two sets of redundant bubbler level sensors to measure wet well level. However, over time, the bubbler sensors were replaced with one radar level sensor and one ultrasonic level sensor in each wet well. Per the original PC-755 design, the system is programmed to use the highest of the two sensors in each wet well and use those values for control.

Decisions on which pumps to select next are based on an operator selectable sanitary pump sequence. In this example (pictured in **Figure 2-6**) the pump sequence will be SN1, SN3 for West Wet Well and SN2, SN4 for East Wet Well.

Figure 2-6
Oakwood Sanitary Pump Selection Ovation Screen

2.2.3.2 Sanitary Pump Auto Operation Scenario

The following is a summary of the sanitary pump automatic operation sequence based on review of the presently programmed Ovation Control Logic. This scenario assumes that all sanitary pumps are operational and that all sanitary pumps are in Auto mode.

In normal operation, the pumps will be in Auto mode and the pumps will be controlled by a target level. The target level is presently 45.0 ft (it was 45.5 ft in original design).

In this scenario, the East Wet Well was selected. Therefore, SG-9 is closed, and SG-10 is open.

If no pumps are presently running, the lead pump in the selected wet well will start if the level is greater than 44.5 ft for more than 30 seconds. Pump SN2 will start at 44.5 ft and run at minimum speed (881 rpm) until the target level of 45.0 ft is reached. The pump speed will then be varied from minimum speed to full speed to maintain the target level utilizing PID control.

If the lead pump is operating at full speed (1175 rpm) [it appears that the Flygt full speed (1185 rpm) was not modified in the programming, carried forward with 1175 rpm] and the selected wet well level is 1.5 ft above the target level for more than 30 seconds, the lag sanitary pump in the selected wet well (SN4 in this case) will be started. SN4 will run at minimum speed (881 rpm) for 30 seconds. SN4 will be ramped up slowly and SN2 will be ramped down so both pumps run at the same speed. Both pumps will then run in tandem (varying speed together) to maintain the target level.

If both pumps are running together maintaining the setpoint between -0.1 and 0.1 error with a flow rate of less than 9.8 cfs (6.3 MGD) for over an hour, the lag pump will shut off. This logic was added to prevent two pumps from running unnecessarily when only one pump is needed to handle the incoming flow. (This was not in the original design)]

If both pumps are running together to maintain the setpoint and both pumps are at full speed (1175 rpm) and the selected wet well (East Wet Well) level is increasing and greater than 47.5 ft for more than 60 seconds, the control system will open SG-9 to make both wet wells active. The lead pump in the other wet well (in this case SN1) will be started and operated at full speed (1175 rpm) to attempt to pump down its wet well.

It should be noted that when three sanitary pumps are running and both wet wells are active, the target level is automatically increased by 1 foot (in this case 46 ft).

Also, when three sanitary pumps are running and the selected wet well level is higher than 44 ft, the pump speed control for the two pumps that are running in tandem is based on the Sanitary capped flow, which is (23.2 cfs [15 MGD] – combined sewer overflow (CSO) Basin Drain to Northwest Interceptor [NWI] Flow). Therefore, the two pumps which are varying in speed may deviate from the target level to avoid exceeding the capacity of the pipeline.

If SN1 succeeds in pumping down its wet well to below 47.5 ft, and both wet wells are decreasing, SG-9 will close, and the pump will stop. Since only one wet well is active again, the target level is returned to its originally entered value of 45 ft. The remaining two pumps in the selected wet well will continue to run and vary their speeds in tandem to maintain the target level.

However, if the three sanitary pumps are running, and the wet wells are still increasing, eventually the lead storm pump will start. When this happens, the lag pump in the selected wet well will stop. The lead sanitary pump in each wet well will continue to run at minimum speed to minimize grit accumulation in the wet wells during the storm event. The lead sanitary pump in each wet well will alternate with its corresponding lag pump each hour.

If the Recirculation Gate is closed during this time, the speeds of the running sanitary pumps will be set to 80% (1057.5 rpm) and continue to run until all storm pumps have been turned off. If the Surge Relief Chamber is higher than 102.98 ft, the sanitary pumps will stop.

[From discussions with the Great Lakes Water Authority (GLWA) and observations during ride - long visits, common practice no longer includes running sanitary pumps during a storm event. Therefore, the logic described in the two paragraphs above should be removed/modified to stop the sanitary pumps when the storm pumps are running during a storm event.]

If the storm event described above did not occur and only the selected wet well is active again, both pumps will continue to run and vary their speeds in tandem to maintain the target level.

If both pumps are operating at minimum speed (881 rpm) and the selected wet well level is 1.5 ft below the target level for more than 30 seconds, the lag sanitary pump in the selected wet well (SN4 in this case) will be stopped.

If the lead pump is operating at minimum speed (881 rpm) and the selected wet well level is 1.5 ft below the target level for more than 30 seconds, the lead sanitary pump in the selected wet well (SN2 in this case) will be stopped.

Sanitary pumps are also programmed to stop if they are in Auto and the wet well level falls below 40 ft.

When all pumps are stopped, the control system will automatically alternate the pump sequence based on run times so near equal runtimes are maintained.

An automatic wet well drawdown was programmed for the sanitary pumps. The time the drawdown starts is configurable by the operator by entering the time in a pop-up window. Presently, the start time is 9:00 AM daily based on the controller clock. The drawdown process will start one pump in each wet well (if the wet well level is greater than 44 ft) and attempt to pump the wet wells down to 42 ft (this was 39.5 ft in original design). A 15-minute timer is programmed to abort the process if 42 ft is not reached during that time. The process will also be aborted if a CSO event is detected (storm pump is running). The pump that draws down its respective wet well will be alternated with its partner each day. [From our discussions with GLWA operations this feature is not utilized.]

It should be noted that in the distant past it was observed that SG-9 appeared to be “leaking”. The West Wet Well level would rise even though SG-9 was fully closed. To combat this problem, logic was added to start a dewatering process on only the West Wet Well whenever the level was greater than 50 ft, the East Wet Well was less than 50 ft, and SG-9 was closed. The dewatering process would last for one hour or stop if the West Wet Well level was below 42 ft.

[The West Wet Well leaking dewatering logic described in the paragraph above, was not part of the original design]

2.2.3.3 Present Sanitary Pumping Unit Moisture and Temperature Monitoring

The Ovation system monitors each sanitary pumping unit’s moisture and temperature sensors. Moisture detection is present to protect the submerged bearings and motor from exposure to the wet well contents. The temperature monitoring sensor protects the motor from an over-temperature condition. The system, as presently programmed, will shut down the pumping unit if either trigger (high moisture or high temperature) is detected by the sensors.

From ride-along insights it appears that the high moisture trigger, as configured, may only trip once if there is a leak which could persist but not necessarily trigger another alarm.

2.2.3.4 Sanitary Pump – Observations While Verifying the Present Programming

The following observations were made as the present programming was confirmed within Ovation. Summarized herein as related to the control narrative but the first may merit attention in the near term to protect the pumps.

2.2.3.4.1 Sanitary Pump – Pump Shutdown Based on Wet Well Minimum Level

The Design Team observed a sanitary pump logic change that was applied to all four sanitary pumps. This change could have been made because the sanitary pumps were being run in exclusively in Manual mode instead of Auto mode and operations were possibly not turning off the pumps at low level. At the time the Ovation programming information was obtained, the observed method of operation was the Manual mode. It appears that logic was added to attempt to stop the pump automatically if the level reached a specified value even though the pump was in Manual mode. The logic was not added correctly, and the level used to stop the pumps was 0 ft. This level will never be reached since the wet well levels are calibrated from 38 to 78 ft. This logic will not work in its present state and recommend removal.

As stated above, the original redundant bubbler level sensors have been replaced with one radar level sensor and one ultrasonic level sensor in each wet well. Per the original PC-755 design, the system is programmed to take the highest of the two sensors in each wet well and use those values for control. It doesn't appear that the sensors are calibrated the same. As the wet wells are being pumped down, L804016C (radar in West Wet well) it appears to get stuck at 43.6 ft frequently when compared to its ultrasonic partner (L804016A) over a period of time. The ultrasonic typically will reach 39 ft during these instances. An example is shown below in **Figure 2-7**.

Figure 2-7
Oakwood Sanitary West Wet Well Level (Radar and Ultrasonic Instrument Output)

A similar phenomenon happens with the East Wet Well sensors. An example is shown below in **Figure 2-8**.

Figure 2-8
Oakwood Sanitary East Wet Well Level (Radar and Ultrasonic Instrument Output)

This behavior will impact any of the processes that use the wet well level to stop the pump. The Design Team recommends that this be addressed. If the level sensors are not calibrated correctly, this will cause problems when stopping the pumps in Auto mode.

2.2.3.4.2 Sanitary Pump – Upstream Isolation Valve Position

SG-9 and SG-10 are always open (Valves in Local Mode), likely due to the valves not closing leak tight. Therefore, what is considered “normal” operation of the sanitary pumps as described in the automatic operation scenario above is not entirely possible (somewhat compromised) with the valves not fully functional.

2.3 Storm and Sanitary Wet Well Sensor Selection Control Logic

The East and West Wet Wells were originally equipped with redundant level sensors on the upstream and downstream sides of the sanitary bar screen. The selection of which level to use for pump system control was performed by the control system through logic. The present control logic was configured to use the higher of the two levels, defaulting to the second sensor only if the primary were to fail. There are no operator actions to change how the level selection operates.

3.0 System Evaluation

The evaluation of improvements to the existing storm pumping system and sanitary pumping system operational strategies summarized in the following section have been separated into distinct categories in each subsection. Each category provides insights to aid in the improvements recommended to the operational strategies in addition to insights that will likely ripple to other elements of the design.

3.1 Operating Data Evaluation

Three years of operating data was acquired from the Ovation system, covering a period from September 2019 through mid-November 2022. The data collected and reviewed for the storm pumping system included pump runtime, speed, pump and motor bearing temperatures, pump and motor vibration, and wet well levels. Additional storm pump related parameters were collected but were not the focus of the evaluations described in this section.

The data collected for the sanitary pumping system included sanitary meter flow rates, pump running, pump speed, wet well levels, NWI level, and surge relief chamber level. Additional sanitary pump related parameters were collected but were not the focus of the evaluations described in this section.

3.1.1 Storm Pump Operating Data Analysis

3.1.1.1 Storm Pump Total Runtime

The storm pump total runtime data was reviewed to evaluate which pumps were operating most within the last three years. The total runtime hours on 9/1/2019 were subtracted from the total hours on 11/15/2022. The runtime hours on each of these dates and the total operating hours for the 3.2-year period analyzed are provided in **Table 3-1**. It is unknown if or when the runtime hours were reset prior to 9/1/2019, except for ST5 which appears to have been reset after the pump rehab was completed in 2022. It does not appear that any of the pump runtimes were reset during the evaluation period, since the runtime hours were always increasing.

Table 3-1 Storm Pump Operating Hours

Storm Pump	Total Runtime as of 9/1/2019	Total Runtime as of 11/15/2022	Total Hours Sep 2019-Nov 15, 2022
ST1	88	188	100
ST2	33	119	86
ST3	9	29	20
ST4	5	31	26
ST5	0.0	0.9	0.9
ST6	119	292	173
ST7	24	85	61
ST8	36	74	38

Note: ST5 - assume runtime reset when pump rehab completed.

The pump runtime data shows that pumps ST1 and ST6 were operated most often, followed by ST2 and ST7, with the fewest hours on ST8, ST4, and ST3 over the last three years. This application is similar to others with combination of VFD speed-controlled and constant speed pumps in which the VFD speed-controlled units are utilized most frequently.

3.1.1.2 Storm Pump Speed

Analysis of the pump speed data for the VFD controlled pumps, ST1, ST2, ST5, and ST6, indicates that these pumps typically run at 75-80% speed. Minimum speeds are set in Ovation system and cannot be changed by the operators. The minimum speeds are presently set to 75% for both the small and large pumps. **Table 3-2** shows the distribution of operating speed ranges for the 5-min averaged pump speed data in an evaluation period. The dominant operation at/near the minimum speed is driven by the common fill/draw operation of the pumping system coupled with the control logic which requires pumps operate at minimum speed when wet well level is dropping.

Table 3-2 Storm Pump VFD Operating Speed Ranges (Percent of Operating Time)

Range	ST1	ST2	Range	ST5	ST6
90-100%	5%	10%	100%	0%	6%
85-90%	1%	1%	93-100%	0%	1%
80-85%	1%	4%	87-93%	0%	2%
75-80%	89%	79%	80-87%	0%	3%
70-75%	1%	3%	75-80%	97%	85%
			70-75%	3%	2%

3.1.1.3 Storm Pump and Motor Vibration Monitoring

Pump and motor vibration sensors provide vibration velocity data to Ovation. Sensors were mounted on the pump discharge head (x-axis and y-axis), motor lower bearing (x and y), and motor

upper bearing (x, y, and z) locations/directions. General observations from review of this data are shown in **Table 3-3**. The constant speed pumps, ST3, ST4, ST7, and ST8 do not show any response or changes in the vibration data when the pumps are running or turned off. All the readings are very low 0.001 or 0.002 in/sec and likely are showing the background electronic signal offset which indicates sensors are not operating properly. ST1 and ST2 indicate vibration readings around 0.15-0.3 in/sec when the pumps are running typically. The maximum vibration readings for these two VFD speed-controlled pumps occur when the pump is not running which is potentially an indicator of sympathetic vibration from other sources in the pump station. The only pump that showed higher vibration readings than ST1 and ST2 was ST6.

Table 3-3 Storm Pump and Motor Vibration Data Summary

Storm Pump	Vibration Velocity Value Observations
ST1	Vibration velocity values observed. Typical values when pump runs were around 0.15-0.3 in/sec (for pump discharge, motor upper and lower bearing (brg) sensors). Some occurrences of higher vibration when pump was not running.
ST2	Vibration velocity values observed. Typical values when pump runs were around 0.15-0.3 in/sec with notable variation from event to event. - Pump discharge x, motor lower brg y, motor upper brg y&z were near upper end of range (0.2-0.3) or higher for motor upper brg x, y, z (0.3-0.5) at times. - Pump discharge y and lower motor x sensors read 0.15-0.2. - Some occurrences of higher vibration when pump ran for short duration with low wet well level (<60 ft) (due to testing?) or when pump is not running.
ST3	None of the pump vibration sensors were registering readings. Vibration measurement was same when pump off/on. Always reads 0.001 or 0.002. The motor upper brg x vibration drifts or was affected by other factors starting July 2022, with some higher spikes when the pump was not running.
ST4	None of the pump or motor vibration sensors were registering readings. Vibration measurement was same when pump off/on. Always reads 0.001 or 0.002.
ST5	Pump out of service for long duration. In 2022, ran a few times after rehab (reinstalled August 2022). Most of run time no vibration values, which is not possible. Some vibration when not running. One occurrence of 0.2-0.5 in/sec on Motor lower brg y and Pump discharge x vib sensors while running. Another with Vib of 0.2 in/sec on motor lower brg y and pump discharge x.
ST6	Pump Discharge x and y vibration was typically in range of 0.2-0.5 in/s, but has a few occurrences with spikes to 0.7-0.9 in/s during operation. Motor Lower Brg x Vib has frequent readings around 0.6 in/s when the pump was not running and no other sensors have elevated readings. The other motor lower and upper brg vibrations sensors were typically between 0.2-0.4 in/s when the pump runs but there were some events (July-Aug 2020, June-July 2021) with readings up to 0.6-1.0 in/s on motor upper brg x & y sensors.
ST7	None of the pump or motor vibration sensors were registering readings. Vibration measurement was same when pump off/on. Always reads 0.001 or 0.002.
ST8	None of the pump or motor vibration sensors were registering readings. Vibration measurement was same when pump off/on. Always reads 0.001 or 0.002.

The vibration velocity values observed indicate:

- The constant speed pump/motor vibration sensors are either all faulty or have been disconnected from the monitoring system.
- There appears to be activities in the pump station which result in elevated vibration levels which are translated through the structure to the pump/motor vibration sensors resulting in elevated values when pumping units are off-line.
 - The off-line elevated vibration levels were evaluated to assess if a correlation with other operating pumps in vicinity of units with elevated vibration amplitudes focused on ST1, ST2, & ST3 based on summary in **Table 3-3**. These are the units for which noted vibration >0.5 in/sec at times when pump not running. The dates with very high vibration spikes (>0.5 ips) for ST1 and ST3 did not have another pump in service. ST2 most of high vibrations for this pump were while the pump was running. When high vibration levels and pump is not running, there were no other pumps running either. There was one common date, 10/20/2022, between all three pumps, but at various times between 5:45-7:00 AM. This time frame could coincide with activities at the pump station which were independent of the storm pumps but resulted in vibration within the structure being transmitted to the pumping units.
- The Hydraulic Institute acceptance criteria (for new or rehabilitated) pumps is 0.17 ips RMS measured at the top of the pump discharge head (identified as “pump discharge” in **Table 3-3** when operating in POR and 0.22 ips RMS when operating in AOR. Elevated vibration velocity values are expected when operating outside the AOR which was occurring over significant portion of the lower wet well water elevations at or near minimum speed. Additionally, ANSI/HI 9.6.4 acceptance criteria includes displacement for units operating at or below 600 rpm, which would include all storm pumps, was not reported or calculated. The vibration levels could be elevated in part due to damage caused from frequent operation outside the AOR coupled with measurements recorded during operation when outside AOR. The measured elevated vibration is expected to be reduced through the rehabilitation of the pumps.
- The information provided in Appendix C of ANSI/HI 9.6.4 includes guidance level vibration values at the top of the motor when motor mounted to the discharge head, with the rather tall “motor stand” between the two components for this installation results in application of those values being a deviation from the intended configuration.

3.1.1.4 Storm Pump Motor Temperature Monitoring

The motor thrust bearing and the pump upper bearing temperature values were reviewed. The temperature data recorded were well below the alarm and trip temperatures (see **Table 2-2**) during pump operation. **Table 3-4** shows the maximum temperatures for each sensor on each pump/motor. The highest pump upper bearing temperatures were about 36 C on ST6 and 35 C on

ST8, while the alarm temperature is 65 C and the trip temperature is 71 C. The highest motor thrust bearing temperature is about 62 C on pump ST8, compared to an alarm temperature of 80 C and a trip temperature of 85 C.

Table 3-4 Storm Pump/Motor Maximum Temperature Data

Storm Pump	Max Temperature, Pump Upper Bearing (C)	Max Temperature, Motor Thrust Bearing (C)
ST1	30	53
ST2	29	55
ST3	32	59
ST4	31	55
ST5	--*	37
ST6	36	58
ST7	32	53
ST8	35	62

*Note: When ST5 back in service (Aug 2022), pump upper bearing temperature sensor not providing good data.

Given the storm pumping units typically do not run continuously for long durations it is not surprising that the maximum temperatures are quite low. It is likely that the equilibrium operating temperature was not reached in most run sequences. For example, motors of this size anticipate 6-8 hours to come up to temperature as confirmed with Ideal Electric.

3.1.1.5 Storm Pump Wet Well Level Monitoring and Associated Pump Operation

There are four level sensors located in the Oakwood pump station wet wells. One in each sanitary wet well, east and west, downstream of the sanitary bar screens, and one in each storm wet well, east and west, upstream of the sanitary bar screens. Review of the wet well level data confirmed that storm pump operation occurs when the level reaches about 73 ft and the pumps were turned off when the level is drawn down to about 65 ft. If the level continues to rise with one pump on then a second pump or more were turned on until start to draw down the wet well.

The levels vary between east and west and upstream to downstream for several reasons including minor differences in level sensor calibration and periodic operational issues. However, a main reason for differences between the upstream and downstream levels is the significant buildup of debris on the sanitary bar screen. Starting in July 2021 the upstream West Wet Well level minimum depth has been rising and has a typical depth between 52.5 ft and 53.5 ft in November 2022, while the downstream level sensor depth is between 41.5 and 49.5 ft as the sanitary pumps cycle. See **Figure 3-1** for approximately 1.5 years of wet well level data. Starting around June of 2022, the East Wet Well also has an elevated level around 58.5 ft during dry weather. The bottom of the storm pump bell is approximately at 53 ft elevation, so during dry weather the sanitary flow was backing up into the storm pumps on the west side due to the debris accumulation on the sanitary bar screen and in the wet well. The sanitary wet well level data and sanitary pump operation are discussed further in the next section.

Figure 3-1
Oakwood Pump Station Wet Well Levels

3.1.1.6 Number of Storm Pumps Running Simultaneously

Data for storm pump operation, on/off times were retrieved from the Ovation system and through the GDRSS portal. The data was reviewed to identify large wet weather events when multiple storm pumps were running at the same time and compared to logbook records with operations staff. The largest events, based on number of pumps in operation are summarized in **Table 3-5**. Based on the event rainfall volumes for the largest events in the September 2019 through October 2022 data set, historical daily rainfall totals back to July 2014 were reviewed to identify earlier rainfall events of similar volume. The GLWA rainfall gauges located closest to the Oakwood storm pump station tributary area were utilized for the event rainfall. Specifically gauge PG004, located at the Water Resource Recovery Facility (WRRF), volumes are shown in **Table 3-5**. The next closest gauge PG006, located in Lincoln Park, was also reviewed but was not as reliable during all events. Based on the pump operation, wet well levels, rainfall volume, and peak hour rainfall for the events initially identified from September 2019 through October 2022, the rainfall totals at PG004 were reviewed and the events with total rainfall of greater than two inches back to July 2014 were selected for further evaluation and added to **Table 3-5**.

The largest number of operating storm pumps was five pumps during three events, 4/30/2019, 8/2/2020, and 8/28/2020. On 8/28/2020 at 3:40 AM, with a maximum wet well level of about 76 ft. The five storm pumps only ran for 5 minutes and then two of the pumps shut off. This period of operation occurred when the pumps were remotely operated prior to an operator arriving on-site, according to the notes in the logbook. Later during the same event, when there was an operator on-site, five pumps ran for 5 minutes while the wet well levels were drawing down from a maximum of about 75-76 ft.

In the eight years of data reviewed there were three events where the Oakwood RTB CSO facility was operated using five storm pumps. Typically, the larger wet weather events require between two and four storm pumps operating during the event peak for the present collection system configuration. Based on the historical maximum number of storm pumps in operation at one time (five) the design team recommends two pumps be rehabilitated simultaneously. This will maintain six pumps available to convey flow from collection system into the retention treatment basin.

Table 3-5 Number of Pumps Operating during Large Wet Weather Events (July 2014-Oct 2022)

Date/Time ^a	Max Number of Pumps On (Pump #s)	Duration Max Number of Pumps On (nearest 5 minutes)	Max ¹ Wet Well Level During or Before Pumps On (ft)	Event Rainfall (PG004, WRRF) (in)	Max Hour (in) ^b
8/11/2014 15:00	2 (ST1, ST7)	60	NA	4.11	1.59
8/16/2016 3:00	2 (ST1, ST7)	165	82 ⁶	3.34	1.75
9/20/2018 0:00	3 (ST1, 2, 3)	65	75	2.20	0.54
9/25/2018 4:50	3 (ST1, 6, 8)	85	75	3.62	1.44
4/30/2019 20:45	5 (ST1, 3, 4, 6, 7)	5 (5-pumps); 50 (4-pumps)	79	3.06	1.11
1/11/2020 8:40	3 (ST1, 2, 3)	5	73	2.66	0.46
7/10/2020 18:55	4 (ST1, 2, 6, 7)	15	78	2.23	1.27
8/2/2020 6:35	5 (ST1, 2, 5, 6, 7)	10	81	2.56	1.01
8/28/2020 3:40	5 (ST1, 2, 4, 6, 8) ²	5	76	4.29	1.13
8/28/2020 7:15	5 (ST1, 2, 4, 6, 8)	5	76		
9/7/2020 3:05	3 (ST4, 6, 8)	15	82	2.35	1.11
7/16/2021 8:55	3 (ST2, 6, 8)	90	78	3.22	1.20
6/25/2021 22:20	2 (ST6, 8) ⁵	75	78	2.16	0.38
7/24/2021 12:35	4 (ST2, 3, 6, 8) ³	45	81	2.14	2.00
8/12/2021 3:10	3 (ST2, 3, 8) ⁴	20	73	2.23	0.85

Table Notes:

NA=Not available (Historian data not readily available earlier than Oct 2017)

^aTime is approximate time start first pump

^bMax hour is based on clock hour, not a rolling average. This may slightly underestimate the max hour rainfall.

¹Max level among the available wet well level sensors (east upstream & downstream, west upstream & downstream)

²Under remote or automatic operation

³Attempted to start two more pumps but could not at time due to overload trip alarms.

⁴Logbook only indicates turning on 3 pumps. Data indicates that attempted to start ST4 and ST7 but each only ran 1 min.

⁵The storm track for this event was along the I-94 corridor. There was less rainfall, only 2.2 inches, near the Oakwood facility tributary area.

⁶Per level noted in logbook. Historian data not readily available earlier than Oct 2017. Only at peak level for short time (~10 min) then 2 pumps start to keep up.

3.1.2 Sanitary Pump Operating Data Analysis

Operating data reviewed from the sanitary pump station included the wet well levels and sanitary pump operating speeds. An example month of data from 10/20/2022 to 11/20/2022 has been provided in **Figure 3-2**, with pump speed on one graph and the four wet well level sensors on a second graph. At the time this data was collected SN-2 in the East Wet Well was out of service. SN-1 and SN-3 pumps were primarily used during dry weather at varying speeds to maintain the West Wet Well downstream level near the target operating level of 45 ft (see West Wet Well level downstream sensor in **Figure 3-2**). When SN-4 was utilized it appears to be running at full-speed continuous. This caused the East Wet Well downstream and upstream to draw down to a minimum of about 42 ft.

There was a large difference between the downstream and upstream (of screen) levels.

- On the west side the upstream level was 53.5ft when SN-1 or SN-3 was running and it draws down to 52.5 ft when SN-4, in the East Wet Well, was running. This was about 8 ft higher than the downstream level of 45 ft. This was an indication of the affect that screenings built up on the bar screen has on the level upstream assuming level sensor condition or calibration is not the cause for the differential.
- On the east side the upstream level was fairly constant at 58.6 ft and the downstream level was 51.8 ft, when SN-4 was not running. The difference between upstream and downstream on the east side is about 6.8 ft, when a pump in the other wet well was running. It was not readily apparent what may cause the differential when no pumps were operating in the East Wet Well. When SN-4 was running the levels are similar upstream and downstream as expected with the lower section of the screen removed.

From the review of the sanitary pumping system data below it appears that refinement of the existing control logic is required. This will include consideration of the intermittently operated third pump running at full speed which requires revision to facilitate operation within AOR. This will likely constrain the variability of level above and below target elevation within the hydraulic capacity of the operating pumping units.

Figure 3-2
Oakwood Sanitary Pump Speed, Wet Well Level and Flow Rate

3.2 Operations Ride-Along Observations and Findings

The Design Team observed the pump operation during five ride-along events from October 31, 2022 through January 19, 2023. The purpose of the operations ride-along visits was to gain an understanding of the present process operations related to the storm and sanitary pumping systems at Oakwood. Information was obtained by observing the pump operations, collecting real-time data from the Ovation control system screens, and at times asking questions of the GLWA staff present at the facility.

The first three ride-along visits were completed by the Design Team lead for pumping improvements, Steve Fehniger, at Oakwood. These visits occurred during storm pumping events on 10/31/2022 with GLWA staff, Ira Hawkins, Art Folks, and Kelvin Jackson, onsite; 11/27/2022 with Art Folks onsite; and 12/15/2022 with Kelvin Jackson, Ira Hawkins, and Robert King onsite. Most of the information gathering and observations summarized below were obtained during these three

visits. Additional ride-along visits were performed which focused primarily on the screenings collection and handling in the screen facility but secondarily included gathering additional information and observations related to the storm pumps by Julie Aichler. These visits were completed on 12/30/2022 with Ira Hawkins onsite; and 1/19/2023 with Art Folks and Ira Hawkins onsite.

3.2.1 Storm Pump System Operations Ride-Along Observations and Findings

The ride-along visits provided an opportunity for the Design Team to observe the operation of the storm pumps at the Oakwood CSO RTB on several occasions as described above. Below is a summary of the findings based on these observations and operator interviews:

- Storm pumps operated manually from Ovation workstation in Control Room when operations staff were on-site during wet weather. At times when facility was not staffed, pumps set to turn on automatically if triggered by lead pump on level.
- Permissive of fine screens and conveyor in operation before starting first pump were active. The fine screens and conveyor were typically operated automatically and start based on wet well level before the first pump starts.
- Consistently turned first pump on at WSE 73 ft. Selection of the storm pump to operate was driven by combination of previous run time balanced with preference to run VFD speed-controlled pump which allowed longer run time to react to changes in the system; i.e. adjust disinfectant dose.
- Did not observe start of a second unit, as the storm events were not large enough to require two pumps operating at the same time to maintain level below two pump run level.
- For each fill/draw cycle a different storm pump was started and pump was turned on when WSE reached 73 ft. Selection of which pump to run appears to be driven by overall run time for each storm pump and providing motor cool down time after each run cycle, if feasible.
- Facility was not operated to try to maintain a constant level.
- Pumps are turned off when wet well level dropped to 65 ft (utilized since Fall 2018). In one case pump turned off at 62.5 ft (ST7).
- Changes to which pump placed in operation occurred when a storm pump was started and the chemical metering pump failed to start. This led to the unit being shut down and an alternate unit being operated instead. In addition, if the flow meter on the selected pump discharge was identified as not functioning then this may lead to shut down of the pump and switch to an alternate pump for which flow meter was operating.

- Levels would decrease for each event after pump start as pumped flow rate would exceed influent flow rate to the facility. This resulted in Ovation selecting minimum speed for each pump (programmed as 75% for both small and large pumps).
- Observations of the instruments on the cooling/seal/lube water during pump operation resulted in the following range of observed values as interpreted from existing pressure gauges and a rotameter:
 - Water pressure measured in storm pump motor room, 68-76 psi.
 - Water pressure measured at intermediate level, 13-24 psi and one reading of 48 psi.
 - Flow rate measured at intermediate level, 12-17 gpm.
- Discharge pressure, as measured at centerline of the discharge pipe via the pressure gauge:
 - ST1: 25-27 psi
 - ST5: 12-13 psi
 - ST6: 10.5 psi
 - ST8: 13 psi
 - ST7: 12 psi
- In general, VFD speed-controlled pumps observed some noise at intermediate level. The VFD pumps were louder with a deeper sound during operation, compared to generally quiet operation of the constant speed pumps. Storm pump 5 made intermittent “boom” sounds, which sounded like hitting a 55-gallon drum when running at minimum speed. The pumps will be noisier when outside AOR. However, the audible sound from pump 5 may not be caused only by operation outside AOR.
- It appears that several vibration sensors may not be functional or out of calibration. ST4, ST7, and ST8 vibration sensors displayed 0 in/sec whether the pump is running or not. Others, for example, ST3 were displaying 0.11 to 0.15 in/sec when off while others in same off condition displayed 0 in/sec.

3.2.2 Sanitary Pump System Operations Ride-Along Observations and Findings

The operations ride-along visits provided an opportunity for the Design Team to observe the operation of the sanitary pumps at the Oakwood CSO RTB on several occasions. These observations typically occurred as transitioned from sanitary to storm pumping. Below is a summary of the findings based on these observations and operator interviews:

- Typically the sanitary pumps are controlled by Ovation in automatic operating mode.

- Normal dry weather operation involves first unit start at WSE 46 ft; low level off level at 41 ft. This range is operator adjustable and has been constrained to 45 to 42-ft.
- In dry weather conditions it has been unusual to run more than two pumps.
- Dry weather average flow is 7-8 cfs which is 4.5-5.2 MGD (one pump running).
- Maximum operating condition is three pumps in service. With four pumps in service flow will overtop the weir in the surge relief chamber intended for recirculation of flow.
- If pumps operated manually typically done from Ovation workstation in the control room. Occasionally need to clear alarm at the VFD if not clear in Ovation.
- It appears that the sanitary pump moisture alarm may be treated like a nuisance alarm with a successful reset either in Ovation or at the VFD resulting in continued operation. From discussions with the Flygt local rep the pump protective device for high moisture will not necessarily repeat the moisture alarm which can then lead to more substantial damage to the motor with continued operation. The observed stator failures demonstrate the extent of damage which can occur prior to pump operation ceasing.
- Common to turn the sanitary pumps off several hours before an anticipated storm event to reduce the flow to the NWI and allow more capacity for wet weather flows from other areas as the collection system is filling. Typically turned off sanitary pumps during the storm event between Wet Well levels 62-67 ft and occasionally lower.
- Range of speed: 881 to 1175 rpm. The rated speed of the Flygt sanitary pumps is 1185 rpm, therefore the pumps are typically operated in the range of 74-99% speed.
- Sanitary pumps were not operated in recirculation mode during wet weather events and have not had a problem with grit clogging the pumps.
- Operations is aware of but does not choose to operate the cleaning cycle (draw down) with the sanitary pumps intermittently.

3.3 Storm Wet Well Minimum Operating Level

The storm wet well minimum operating level was evaluated by consideration of three key focus areas:

- Pump intake design acceptance criteria at minimum operating level
- Adequate NPSH margin
- Motors non-overloading for the new conditions of service

The above areas were evaluated in the stated order to determine the minimum storm wet well level while meeting associated constraints. The contract established a minimum of 65 ft for the lead storm pump shut off level as a goal. A summary of the evaluation for each focus area follows:

3.3.1 Pump Intake Design – Physical Model Study Acceptance Criteria

The pump intake design acceptance criteria, as summarized in ANSI/HI 9.8 Pump Intake Design standard relative to physical model studies, were evaluated through the physical hydraulic model study performed by Clemson Engineering Hydraulics (CEH). The details of the model study were included in the report prepared by CEH included as Appendix A.

Key findings included that the minimum water surface elevation at which the physical model study acceptance criteria are within tolerance for each pump size were as follows: 61 ft for the small pumps and 62.5 ft for the large pumps.

These values are an improvement relative to the goal 65 ft minimum level but require further evaluation in the other two areas summarized below to determine if technically feasible to shut down the lead pump at these lower minimum water surface elevations.

3.3.2 Adequate NPSH Margin

The NPSH Margin for the small and large storm pumps was calculated with the minimum water surface elevations determined by the physical model study as an input. The calculation also utilized the maximum combined sewage temperature, actual NPSH datum of each pump, and operation in the AOR with associated greater NPSH margin ratio.

The evaluation determined that the NPSH margin is adequate at the minimum water surface elevation for each pump with a margin ratio of 1.2 in accordance with ANSI/HI 9.6.1 for the pump impeller material (stainless steel), service (wastewater) and horsepower (≥ 100 HP).

This area of focus determined operation at the model study determined lower water surface elevations is technically feasible which resulted in evaluation of the motor load focus area summarized below.

3.3.3 Motors Non-overloading for the New Conditions of Service

The evaluation of the motor load capability for the new conditions of service (lower wet well elevation with resultant greater total head and revised minimum speed to maintain operation within the AOR) resulted in a focus on the available motor torque at minimum speed as compared to the pump required torque.

The evaluation included consideration of pump required torque at the higher head, lower speed condition and compared to the motor manufacturer's input regarding the motor torque available for these operating conditions to determine the motors will not be overloaded or unable to provide sufficient torque at the new conditions of service. Ideal Electric indicated existing motors can

operate at the horsepower and speeds provided (small pump: 88% speed , 885 HP, 523 rpm; large pump: 92% speed, 1,632 HP, 410 rpm) with no modifications or reduction in motor life expectancy.

3.3.4 Storm Wet Well Minimum Operating Level Conclusions

Therefore, based on the evaluation of the three focus areas summarized above the storm pumps can operate to shut off wet well levels (61 ft for the small pumps and 62.5 ft for the large pumps) lower than present practice (65 ft) although minimum pump speed will be higher than present practice to maintain operation within AOR as described in the next section.

3.4 Storm and Sanitary Pump System Curve Envelope & Overlay Plots – Viable Operating Conditions & Speeds

The storm and sanitary pump system curve envelopes were determined and then compared to the pump performance curves in overlay plots to assess the range of feasible operating conditions and speeds the pumps could operate for these applications and maintain operation within the AOR of each pumping unit. In addition, consideration was given to operation focused within the POR to the extent feasible.

The pump performance curves with AOR and POR for the small and large storm pumps as well as the sanitary pumps were included in Section 2.

3.4.1 Storm Pumps

3.4.1.1 System Curve Envelope Development

The storm pump system curves were developed using a spreadsheet-based tool developed by CDM Smith which develops system curves for range of static head over which the system will operate and estimates losses due to pipe friction and minor losses.

For this application, each pump is directly piped to the screen facility inlet chamber with a vertical standpipe terminated above downstream maximum water level as a hydraulic break such that the pumps do not convey flow in a common discharge header.

The system curve envelope covers the range from minimum water surface elevation for each pump (small and large) to the maximum level. Minimum levels selected based on the evaluation summarized in section above and maximum level based on original design which has worked in historical practice to minimize basement backups.

3.4.1.2 Overlay Plots

Overlay plots which combine the system curve envelopes discussed above with the pump performance curves for the application specific hydraulic performance characteristics are presented in **Figures 3-3, 3-4, and 3-5** for the small and large pumps, respectively.

The overlay plots reflect the output of a spreadsheet tool developed by CDM Smith for the graphical representation of the pump coverage of the system curve envelope.

The overlay plots provide a visual tool to estimate the operating range of each pump in the application with a focus on maximizing operation in the POR to extent feasible and avoiding sustained operation outside the AOR in accordance with pump manufacturer's input on operating range and with consideration of applicable HI standards and guidelines. The speed-controlled pumps include a series of speed reduced performance curves to represent performance over range of speed steps.

Figure 3-3
 Oakwood Small Storm Pump Overlay Plot

Figure 3-4
Oakwood Large Storm Pump Variable Speed Overlay Plot

Figure 3-5
Oakwood Large Storm Pump Constant Speed Overlay Plot

In the figures above the acceptable operating envelope was shaded in blue. The range of conditions shown have been used for the development of the operational strategy improvements described below to determine how the pumping units should be operated. In addition, the minimum acceptable speed to maintain operation primarily in the POR to minimize operational costs and over entire operating envelope within the AOR (excludes the unstable portion of the performance curve) for each pump size are shown with minimum speed for small pumps of 88% speed and for large pumps 92% speed.

Although the overlay plots provide a “one pump” view of the system, the summation of capacities from each operating pump can be determined by summing capacities for various pump combinations/operating scenarios to determine the overall capacity and the gap (step in flow rate capacity) that will occur as the number of operating pumps change. **Table 3-6** provides an example with the large VFD speed-controlled pumps started first, followed by the small VFD speed-controlled pumps, then the constant speed pumps. Due to the capacity range of each pump the steps

(gaps) of flow rate are present despite ramping the operating speed-controlled pumps down to minimum speed when turning on the next pump.

Table 3-6 Storm Pump Sequence to Minimize the Capacity Gaps at Pump Transitions

Combination Order as Flows Increase	Operating pump combination			Min Flow, small VFD (mgd)	Max Flow, small VFD (mgd)	Min Flow, Large VFD (mgd)	Max Flow, Large VFD (mgd)	Flow, Large Const (mgd)	Total Min Flow (mgd)	Total Max Flow (mgd)	Limitation for Min Flow	Overlap with previous combo (mgd)	Pump, Min speed, %	Comments
Sequence 2	Number of Small VFD	Number of Large VFD	Number of Large constant	Values only used if # on is >0										
1	0	1	0			146	174		146	174	Min operation with given pump		92%	Starts with large VFD pump, then second large VFD, then small VFD, and constants last.
2	0	2	0			148	175		296	350	92% speed	-122	92%	Min flow at WW=73', max flow at WW=75' & 100% speed
3	1	2	0	84	97	150	175	175	384	447	92% speed	-34	92%	Min flow at WW=75.5', max flow at WW=76' & 100% speed
4	2	2	0	85	98	151	176	176	472	548	92% speed	-25	92%	Min flow at WW=76', max flow at WW=76.5' & 100% speed
5	2	2	1	85	98	152	176	176	650	724	92% speed	-102	92%	Min flow at WW=76.5', max flow at WW=77' & 100% speed
6	2	2	2	85	98	153	177	177	830	904	92% speed	-106	92%	Min flow at WW=77', max flow at WW=77.5' & 100% speed
7	2	2	3	85	98	154	178	178	1012	1066	92% speed	-108	92%	Min flow at WW=77.5', max flow at WW=78' & 100% speed. This combination covers Design Capacity Peak flow of 1660 cfs with

Notes: 1. Assume WSE is increasing 0.5' as each additional pump is called to turn on.
2. All VFD speed-controlled pumps operated at the same speed. This limits the operating speed of the small pumps to 92% to match minimum speed for the large pumps.
3. Flow rate is rounded to nearest whole number. At the given WSEs the flow rate has limited change as increase WSE in 6" increments, therefore rounded flow rate is the same across some increases in WSE.

3.4.2 Sanitary Pumps

3.4.2.1 System Curve Envelope Development

The sanitary pump system curve envelope was developed using AFT Fathom for the pressurized portion of the system and Visual Hydraulics for the gravity portion.

For this application each set of dedicated pumps convey flow into a common header that is then combined into a single force main downstream of the West Wet Well connection. Under nearly all operating conditions, the system transitions to gravity flow at the first manhole.

The system curve envelope covers the range from minimum water surface elevation to the maximum level. Minimum levels selected based on the operating practice and minimum

submergence required by Flygt based on their input to the historic maximum if sanitary pumps were to be operated during a storm in recirculation mode in the future.

The following summary provides background regarding the system curve development with a focus on the downstream water surface elevation.

The Storm Water Management Model (SWMM) hydraulic modeling of the collection system established a maximum dry weather water surface elevation of 94.1 ft in the sanitary manhole immediately downstream of the surge relief chamber. Visual Hydraulics (VH) was used to establish the upstream water surface elevation at the discharge of the sanitary pump force main (first manhole). This VH determined upstream water surface elevation was subsequently input into AFT Fathom as the “downstream” water surface elevation.

Under all modeled scenarios in which the surge relief chamber weir was not overtopped, the discharge of the 20” sanitary force main was not submerged. Therefore, the downstream water surface elevation input into the AFT Fathom model was 98.33 ft, equivalent to the centerline of the force main connection to the first manhole.

Under modeled scenarios with a high-water surface elevation (above 62 ft) in the sanitary wet well, it was assumed that only one sanitary pump was in use and that all flow passed over the surge relief chamber weir (recirculation mode). In these scenarios, the water surface elevation at the sanitary pump force main discharge was 98.6 ft, which was input into AFT Fathom as the model’s downstream water surface elevation.

The other elements of the system including pipe/fittings configuration and range of upstream water levels were input into the AFT Fathom model to complete the system and determine the system curve envelope.

3.4.2.2 Overlay Plots

Overlay plots which combine the system curve envelope discussed above with the pump performance curves for the application specific hydraulic performance characteristics are presented in **Figures 3-6, 3-7 and 3-8** for three pump combination operating conditions (one pump, two pump and three pump operation).

A sensitivity analysis was performed to determine how much the system curve varied from one pump to the next. The findings determined that the variation is limited relative to the total head such that these curves are representative of the four pump positions.

Refer to the general overview information regarding overlay plots in the storm pump overlay plot section above.

Figure 3-6
 Oakwood Sanitary One Pump Overlay Plot

Figure 3-7
 Oakwood Sanitary Two Pump Overlay Plot

Figure 3-8
Oakwood Sanitary Three Pump Overlay Plot

In the sanitary pump overlay figures the acceptable operating envelope was shaded in blue. The range of conditions shown have been used for the development of the operational strategy improvements described below to determine how the pumping units should be operated. In addition, the minimum acceptable speed to maintain operation within the AOR are shown as a function of wet well water surface elevations due to the limited coverage of the system curve envelope on the right side of the performance curve. The right limit of the AOR was discussed with Xylem Flygt as summarized in Section 2.

Although the overlay plots provide a one, two and three pump view of the system, the summation of capacities is also represented in **Table 3-7** with associated operational constraints identified. The table demonstrates that limited overlap at pump transitions will be feasible if system is operated as represented in the overlay plots.

Table 3-7 Sanitary Pump Sequence Summary Tabulation

Combination Order as Flows Increase	Operating pump combination	Total Min Flow (mgd)	Total Max Flow (mgd)	Limitation for Min Flow	Overlap with previous combo (mgd)	Pump, Min speed, %	Comments
Sequence 1	Number of Sanitary Pumps (VFD)						Starts with one pump, transition to two pumps, then three pumps with constantly rising wet well
1	1	2.5	5.8	Min operation at WW WSE=41	NA	75%	Min flow at WW=41' (75% speed), max flow at WW=46' & 95% speed
2	2	3.5	8.6	70% speed	2.3	70%	Min flow at WW=46', max flow at WW=55' & 80% speed
3	3	8.3	14.1	70% speed	0.3	70%	Min flow at WW=55', max flow at WW=62' & 80% speed
1	1	1.8	3.65	60% speed		60%	Separate consideration of operating range for 1 pump between 62' and 78' at 60% speed

Notes: 1. Table provided sanitary pump example operations - starts with single pump between 40.2-46 ft, then 2 pumps between 46-62 ft, & 3 pumps up to 62 ft.
2. Refer to last row for 1-pump in operation (if recirculation mode reinstated) between 62 ft and 78 ft at constant reduced speed of 60%.

3.5 Storm and Sanitary Wet Well Sensor Selection Control Logic Evaluation

The importance of reliable level sensor signals and associated control logic utilized to select the signal for control basis of each pumping systems cannot be overstated. With a focus on the operational strategy in this TM, the Design Team has considered of the existing sensor selection logic summarized in Section 2 and has determined revision to address limitations of the present logic and modify to reflect the practice at other GLWA pump stations is required. A description of the proposed control logic follows.

As part of the system improvements, the control logic utilized for storm and sanitary wet well level selection will be updated to use the standard multiple-transmitter selection (2X-Select) logic. The new system will still use the two redundant level sensors as inputs, while the output signal used by the pump system could be one of five options:

- AVG - Average of the two inputs
- Max - Higher value input
- Min - Lower value input
- A – Input A
- B – Input B

Selection of which mode to use will be performed by the operator through a control faceplate. The standard faceplate shows the two input levels, current mode, and output level.

The updated logic will also check the quality of each input signal and defaults it's selection mode if one signal goes into bad quality due to a failed instrument, broken wire, etc. For example, if AVG is selected and input A fails, the logic will default to B mode. The logic inhibits the selection of a failed input. Once the failed input is returned back to service, the operator can switch modes.

3.6 CS-299 report and Brown & Caldwell (BC) TM Operational Strategy Recommendations

The CS-299 and BC TM operational strategy recommendations were reviewed and evaluated relative to the Design Team's evaluation of these systems. A list of the recommendations which differ from those discussed above are provided with an explanation of why not changing our approach to the evaluation.

- Potential storm pump setpoint modifications included:
 - Operating SP1 and SP2 within a speed range of 85 to 100% to avoid unstable operating zones.
 - *Design Team recommended range of 88 to 100% to maintain operation primarily in the POR and within AOR over the system curve envelope in lieu of the proposed speed range.*
 - Operating SP5 and SP6 within a speed range of 85 to 100% to avoid unstable operating zones.
 - *Design Team recommended range of 92 to 100% to maintain operation primarily in the POR and within AOR over the system curve envelope in lieu of the proposed speed range.*
- Lowering lead storm pump shut off water surface elevation from 71 ft to 65 ft.
 - *Design Team recommended a minimum of 61 ft for the small pumps and 62.5 ft for the large pumps in lieu of the proposed 65 ft.*

- Potential sanitary pump setpoint modifications included the following summarizing the setpoints from Table 5-5 of the BC TM:

Water Surface Elevation (ft)	Number of Pumps On	Motor Speed (%)	Approximate Discharge Flowrate Range (mgd)
EL 40 to EL 46	1	75% - 100% (varies)	2 - 6 mgd
EL 46 to EL 50	2	75% - 100% (varies)	6 - 14 mgd
EL 50 to EL 60	2	100% (fixed)	14 - 15 mgd
EL 60 to EL 72	3	85% (fixed)	16 - 20 mgd

- The Design Team recommended the operating conditions summarized in Table 3-8 for the sanitary pumps in lieu of the above to maintain operation in the AOR over the range of operating conditions.

Table 3-8 Sanitary Pump Operational Protocol

Wet Well Level (ft)	No. of Pumps On	Motor Speed (%)	Approx. Flow Rate (MGD)	Notes
40.2 to 46	1	75 to 95	2.3 to 5.8	Normal dry weather 41-46 with intermittent cleaning cycle to 40.2
46 to 62	1	75 to 80	2.9 to 4.9	Not anticipated to occur frequently (expect multiple pumps on-line at higher levels)
62 to 78	1	60 (constant)	1.8 to 3.7	If recirculate flow during wet weather
46 to 62	2	70 to 80	3.5 to 9.5	
46 to 62	3	70 to 80	5.2 to 14.1	Potential to raise upper motor speed slightly if additional capacity required

Note: Flow rate range stated was over full wet well level range for each operating condition.

The conditions proposed in the BC TM would result in operation outside the AOR. Therefore, the speed range as a function of wet well level and number of pumps in operation varies as summarized in **Table 3-8** and as shown graphically in the overlay plots. The motor speed upper limit could be expanded a couple percent for two and three pump operation if greater overall capacity required as approach potential wet weather event.

The selected Flygt pumps are unable to cover the right side of the system curve envelope as would be optimal for operational flexibility resulting in varied speed restrictions to maintain operation in the AOR. If additional pumps are purchased in the future consideration to an alternate hydraulic design which works within the horsepower constraints of the electrical gear and VFDs would be beneficial.

4.0 Conceptual Storm and Sanitary Pump Improved Operational Strategies Improvements

The conceptual operational strategies summarized in this section reflect Design Team proposed improvements to the present operational strategies for storm and sanitary pumping systems when operated in Auto mode based on evaluations and operational insights gained as summarized in Sections 2 and 3.

The conceptual improvements are summarized in the following subsections utilizing an improved description of the existing operational strategy included in Sections 2.1.3 (Storm) and 2.3.3 (Sanitary) for the present (existing) Auto mode operational strategy.

4.1 Storm Pumping System

The following is a summary of the improved storm pump Auto mode operational strategy. This strategy assumes that all storm pumps are operational and that all storm pumps are in Auto mode.

Prior to a storm event, the operator selects ST sequence. The sequence is selected from a selection screen in Ovation. The follow sequence is recommended to minimize the size of the gaps when transitioning from one pump combination to the next and is captured greater detail in Section 3: ST5, ST6, ST1, ST2, ST3, ST4, ST7 (or ST8). This sequence includes VFD speed-controlled pumps in operation before the constant speed pumps.

This example is based on the design condition in which the wet well level continuously rises requiring all seven duty pumps to be turned on.

This sequence no longer utilizes the target level to maintain in the wet well within so many feet of a target level due to limitations on the operating range of the pumps within their respective AOR's as constrained by the system curve envelope and limitations in stored volume relative to pump capacity. Instead of this method a ramp up/then down of level with associated pump starts/then stops was summarized.

The decision regarding lead pump selection is guided in part by desire to distribute the runtime between the storm pumps and if alternate lead pump is selected the incremental increase in flow when another pump is turned on will likely be greater.

During a wet weather event, the wet well levels will increase. When the wet well level rises to or above 73 ft, the first storm pump in the sequence will start. The pump will run at minimum speed (523 rpm for small pumps (88% speed); 410 rpm for large pumps (92% speed)) for 75 seconds to allow the discharge piping to fill up. After the 75-second timer expires, the control system will modulate the pump speed to attempt to maintain the level below second pump on level (75 ft). Below 73 feet pump will operate at minimum speed, between 73 and 75 ft pump will ramp up linearly to be at full speed when level reaches 75 ft.

The Ovation control system will compare the wet well level with the Ramping Level Setpoint. As the wet well level rises above the last ramping level setpoint, the control system will increase the speed of the speed-controlled pumps to attempt to maintain the wet well level. Similarly, if the wet well falls below the ramping level setpoint, the control system will decrease the speed to attempt to maintain the wet well level. If the lead pump is running at full speed and the wet well level is at or above 75 ft for more than 60 seconds, Ovation will start the next storm pump in the sequence.

The second pump will run at minimum speed for 75 seconds. Then the pump will ramp up and the operating pump will slow down to match speeds so not such a substantial increase in flow rate with additional pump. Both pumps run at the same speed (if a combination of small and large variable speed pumps the greater minimum speed will be utilized) and will be modulated to maintain the last Ramping Level Setpoint (75 ft).

If the wet well continues to rise and the two running pumps are at maximum speed and the wet well level is at or above 75.75 ft for more than 60 seconds, Ovation will start the next storm pump in the sequence. The third pump will run at minimum speed for 75 seconds. Then the pump will ramp up and the three operating pumps will slow down to match speeds and modulate speed to maintain the 75.75 ft setpoint.

If the wet well continues to rise and the three running pumps are at maximum speed and the wet well level is at or above 76.25 ft setpoint for more than 60 seconds, Ovation will start the next storm pump in the sequence. The fourth pump will run at minimum speed for 75 seconds. Then the pump will ramp up and the four operating pumps will slow down to match speeds and modulate speed to maintain the 76.25 ft setpoint.

If the wet well continues to rise and the four running pumps are at maximum speed and the wet well level is at or above the 76.75 ft setpoint for more than 60 seconds, Ovation will start the next storm pump in the sequence.

In this operational strategy, the remaining pumps in the sequence are constant speed pumps. The constant speed storm pumps are programmed internally (not through Ovation) to ramp up over a range of 0-180 seconds, with an initial setting of 75 seconds to allow discharge piping to fill up as the pump speed is increasing to full speed. After the constant speed pump has completed ramp up, the VFD speed-controlled pumps will all decrease to minimum speed to minimize the step increase in flow rate and then continue to modulate to maintain the last Ramping Level Setpoint (76.75 ft) while the constant speed pump runs at full speed.

If the wet well continues to rise and the five running pumps are at maximum speed and the wet well level is at or above the next Ramping Level Setpoint (77.25) for more than 60 seconds, Ovation will start the next storm pump in the sequence. The VFD speed-controlled pumps will step down in speed as described for five pumps in operation followed by continuation of modulation of speed to maintain the last wet well Ramping Level Setpoint while the constant speed pumps will run at full

speed. This sequence will continue until seven pumps are operating (7th pump on at 77.75 ft) or the wet well level begins to fall.

As the wet well level begins to fall, the pumps will shut down in order (first started of each pump size/ speed control type (VFD speed controlled or constant) will be first off as step pumps off to allow runtime distribution). As stated before, the VFD speed-controlled pumps will continue to modulate to maintain the Wet Well Falling (since level decreasing but same numerical value as the corresponding rising level setpoint) Level Setpoint while the constant speed pumps will run at full speed. If the wet well continues to fall and the four VFD speed-controlled pumps are running at minimum speed and the wet well level is 0.5 or 0.75 ft (match the same set point values as used for rising level) below next Falling Level Setpoint for more than 60 seconds, Ovation will stop the last storm pump that was started in the sequence. The VFD speed-controlled pumps will continue to modulate to maintain the Wet Well Falling Level Setpoint while the remaining constant speed pumps will run at full speed. If the wet well continues to fall and the four VFD speed-controlled pumps are running at minimum speed and the wet well level is 0.5 or 0.75 feet below the next Falling Level Setpoint for more than 60 seconds, Ovation will stop the next storm pump that was started in the sequence. This sequence continues with each pump turning off in the reverse order that they turned on until the last VFD speed-controlled pump is operating.

If the wet well continues to fall, the final VFD speed-controlled pump will continue to run at minimum speed until the level falls to 62.5 ft (large pumps) or 61 ft (small pumps) for 15 seconds.

4.1.1 Storm Pumping Unit Vibration and Temperature Monitoring

The Ovation system will continue to monitor each storm pumping unit's vibration and temperature sensors.

4.1.1.1 Vibration Monitoring

The vibration sensors, as presently configured and if sensors fully functional, cause an alarm for any of the pumping units if a sensor value exceeds 0.85 in/s independent of the location (pump, lower motor or upper motor) of the sensor. In preliminary design phase a recommended alternate set point for vibration alarm, which will likely vary by sensor location, as well as clarification of the vibration velocity units (peak or RMS) will be determined to refine this part of the operational strategy. The recommended alarm and trip set points will consider alignment with HI standards guidance and the pump manufacturer.

Discussion with GLWA is needed regarding their preference for the Multilin motor protection device for a representative pump to shut down if the vibration trip value is in excess of pump manufacturer recommended trip value. Presently the pumps do not shut down if a vibration trip set point is reached. The Design Team recommends shut down of the pump if this level of vibration is detected to minimize damage to the pump if this will not result in basement backups (if another pump can be started if wet well level is close to maximum).

4.1.1.2 Temperature Monitoring

The temperature sensor monitoring by Ovation includes set points for alarm and trip temperatures. In Section 2, **Table 2-2** provides the alarm and trip temperatures for the storm pumps. This protection due to elevated temperatures will continue to be part of the operational strategy.

The design team will confirm the present alarm and trip set points for the bearings with the pump and motor manufacturers in the preliminary design phase.

4.2 Storm and Sanitary Wet Well Level Sensor Selection

Section 3.5 includes the proposed operational strategy for the selection of the level sensor which is to be utilized for control at each level monitoring location (“upstream” for the storm wet well and “downstream” for the sanitary wet well).

As part of the system improvements, the control logic utilized for storm and sanitary wet well level selection will be a match to similar systems in other GLWA level sensing applications to use the standard multiple-transmitter selection (2X-Select) logic. The new system will still use the two redundant level sensors as inputs, while the output signal used by the pump system could be one of five options:

- AVG - Average of the two inputs
- Max - Higher value input
- Min - Lower value input
- A – Input A
- B – Input B

Selection of which mode to use will be performed by the operator through a control faceplate. The standard faceplate shows the two input levels, current mode, and output level.

4.3 Sanitary Pumping System

The following is a summary of the improved sanitary pump Auto mode operational strategy.

This strategy assumes:

- All sanitary pumps (four equally sized submersible pumps) are operational.
- All sanitary pumps are in Auto mode.
- Isolation gates (pinch valves) in upstream junction chamber (SG-9 and SG-10) are operational such that one sanitary wet well can be isolated from the influent flow which was not feasible at the time of this writing. Gates are planned for replacement as part of the Oakwood District Intercommunity Relief Sewer (ODRIS) project (No. 2002655). This fully functional gate

condition is critical for “normal” operation of the sanitary pumps as described below to be entirely feasible (unable to isolate wet well from influent flow) with the gates not fully functional.

Normal (Dry Weather) Operation (41 – 46 ft)

In normal (dry weather) operation, the pumps will be in Auto mode and the pumps will be controlled by a target level. The target level is to be operator adjustable (from 44.5 ft to 45.5 ft) and is assumed to be 45.0 ft for this example.

In this example, the East Wet Well was selected. Therefore, SG-9 is closed, and SG-10 is open. The opposite would apply if West Wet Well was selected.

If no pumps are presently running, the lead pump in the selected wet well will start if the level is greater than 44.5 ft for more than 30 seconds. Pump SN2 will start at 44.5 ft and run at minimum speed (75% = 889 rpm) until the target level of 45.0 ft is reached. Target level will be operator adjustable with the lead pump start level 6 inches below the target level. The pump speed will then be varied from minimum speed to maximum speed (95% = 1126 rpm) to maintain the target Level utilizing existing PID control.

For dry weather flow conditions recommend one pump in service with associated higher approach and discharge velocity for this high grit wastewater and operation at higher efficiency (in POR) as compared to two pump operation. This will include operation over level range of 46 to minimum level of 41 ft. Recommendation is based upon observations and discussions as part of the ride-along visits, where the Design Team identified one pump operation is common and suitable to convey the average dry weather flow (7-8 cfs which is 4.5-5.2 MGD).

Wet Weather Event Approaching (46 – 62 ft)

If the lead pump is operating at maximum speed at 46 ft (1126 rpm) and the selected wet well level is above the dry weather flow maximum (46 ft) level for more than 30 seconds, the lag sanitary pump in the selected wet well (SN4 in this case) will be started. SN4 will run at minimum speed (70% = 830 rpm) for 30 seconds. SN4 will be ramped up slowly (rate to be determined in design phase) and SN2 will be ramped down so both pumps run at the same speed. Both pumps will then run in tandem (varying speed together) to maintain the level between 46 and 55 ft. Pump speed will be ramped up linearly from minimum after second pump start-up complete up to maximum speed (80% = 948 rpm) at 55 ft. Speeds are constrained to maintain operation within AOR.

If both pumps are running together to maintain the setpoint (55 ft) and both pumps are at maximum speed (948 rpm) and the selected wet well (East Wet Well) level is increasing and greater than 55 ft for more than 60 seconds, the control system will open SG-9 to make both wet wells active. The lead pump in the other wet well (in this case SN1) will be started and ramped up slowly (rate to be determined in design phase) and SN2 and SN4 will be ramped down so all three pumps run at the same speed. The three pumps will operate together to attempt to control the wet well rise ramping linearly from minimum (830 rpm) at 55 ft to maximum at 62 ft (948 rpm).

It is recognized that the West Wet Well in this example will fill independent of the SG-9 position as at the level indicated for third pump start (55 ft) the gate will be overtopped and enter the wet well.

If the addition of SN1 succeeds in pumping down its wet well to below 46 ft, and both wet wells are decreasing, SG-9 will close, and the SN1 pump will stop. The remaining two pumps in the selected wet well will continue to run and vary their speeds in tandem to maintain the target level.

However, if the three sanitary pumps are running, and the wet wells are still increasing, eventually the lead storm pump will start. When this happens, the three sanitary pumps will stop at 62 ft assuming that the recirculation mode during wet weather event will not be operated based on limited value identified by operations.

One pump Operation Above Dry Weather Operation Level Range (46 – 62 ft)

For the unusual operating condition in which only one pump is operated between 46 and 62-ft the speed limitations to maintain operation within AOR are from minimum of 75% to maximum of 80%.

Maximum Flow Rate Constraint

The maximum flow rate the sanitary pumping system was intended to convey to NWI was determined to be 23.2 cfs (15 MGD) as part of the original design. Based on the above operational scenario with associated maximum operating speeds over the wet well ranges stated to maintain operation within the AOR this flow rate will not be exceeded. Rather the maximum at 62 ft will be approximately 22 cfs (14.1 MGD) as shown in the three-pump overlay plot in Section 3.

This revision is aligned with the one sanitary pump operational constraint focused on maximum sanitary flow rate including CSO basin dewatering of 23 cfs after a wet weather event.

Recirculation Mode (62 – 78 ft)

If recirculation mode during wet weather events is restarted, for levels above 62 ft the lead sanitary pump in each wet well will alternate running at fixed speed each hour to minimize grit accumulation near the pumps in the wet wells during the storm event. The lead sanitary pump in each wet well will also alternate with its corresponding lag pump each incremental start of recirculation mode in each wet well.

The speed of the running sanitary pump will be set to 60% (711 rpm) to maintain operation within AOR and continue to run until all storm pumps have been turned off. If Surge Relief Chamber is higher than 102.98 ft, sanitary pump operation will stop.

From discussions with GLWA and observations during ride-along visits common practice no longer includes running sanitary pumps during a wet weather event. Therefore, the logic described in this subsection should be removed/modified to stop the sanitary pumps when the storm pumps are running during a storm event if there is no intent to potentially restart this activity in the future.

Drawdown (Cleaning) Cycle (44 – 40.2 ft)

An automatic daily wet well drawdown for the sanitary pumps should be restarted as this operational practice has not been utilized recently given this could reduce the accumulation of debris thereby increasing the duration between manual cleaning. This procedure has been reviewed with Xylem Flygt which indicated that this operation is acceptable down to 40.2 ft (minimum water level for the sanitary pumps). The time the drawdown starts is configurable by the operator by entering the time in a pop-up window. In this example, the start time is 9:00 AM daily based on the controller clock. The drawdown process will start one pump in each wet well (if the wet well level is greater than 44 ft) and attempt to pump the wet wells down to 40.2 ft. A 15-minute timer is programmed to abort the process if 40.2 ft is not reached during that time. If practice identifies that the 15-minute timer is not allowing the cycle to complete then this time could be extended given not limited by motor exposure to air with the Flygt motors equipped with a cooling jacket. The process will also be aborted if a CSO Event is detected (storm pump is running). The pump that draws down its respective wet well will be alternated with its partner each day. If desired to increase the drawdown frequency to two times/day provide capability to accommodate two cycles/day.

Dewatering Cycle if Leaking Isolation Gate (41 – 49.5 ft)

It should be noted that in the past it was observed that SG-9 appeared to be “leaking”. Although this should not be an area of concern after the SG-9 and -10 gates are replaced, as part of a separate contract, in the future if the West Wet Well level rises even though SG-9 was fully closed (or vice versa) then a dewatering cycle will be initiated. To start a dewatering process on only the wet well with leaky isolation gate whenever the level is greater than 49 ft, the East Wet Well is less than 49 ft, and SG-9 was closed. The dewatering process would last for one hour or stop if the West Wet Well level was at 41 ft.

Other Operational Strategy Requirements

Sanitary pumps will be programmed to stop if in Auto and the wet well level falls below 40.2 ft.

When all pumps are stopped, the control system will automatically alternate the pump sequence based on run times so similar runtimes are maintained.

4.3.1 Sanitary Pumping Unit Moisture and Temperature Monitoring

The Ovation system monitors each sanitary pumping unit’s moisture and temperature sensors. Moisture detection is present to protect the motor internal components from exposure to the wet well contents. The temperature monitoring sensor protects the motor from an over-temperature condition. The system, as presently programmed will shut down the pumping unit if either trigger (high moisture or high temperature) is detected by the sensors. This shutdown practice should continue and should result in pump inspection to maximize the service life of each pumping unit.

Note that a finding from the ride-along insights discovered that the high moisture trigger, as configured, may only trip once if there is a leak which could persist but not necessarily trigger

another alarm. This highlights the importance to inspect the pump if this shutdown trigger were to occur.

4.4 Storm and Sanitary Wet Well Sensor Selection Operational Strategy Improvements

Refer to Section 3.5 for recommended operational strategy improvements.

5.0 Summary, Recommendations and Key Decisions

The review of operating data, enhanced understanding of operational practices gained from operations ride-along visits, evaluation of minimum storm pump operating level, determination of operational constraints to maintain storm and sanitary pumps within AOR, maintenance of storm pump maximum operating level to minimize potential for basement backups and consideration of recommendations from past studies provided the basis for improvements to the operational strategies.

The recommended improvements to the storm and sanitary pumping system operational strategies are captured in the conceptual strategies stated in Section 4. The improvements focus on maintaining operation of each pump within the AOR and to the extent feasible within the POR to maximize reliability/service life, optimize operation and reduce maintenance and downtime.

5.1 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

- Speed range changes for storm and sanitary pumps
- Changes to minimum wet well level (lead pump shutoff) for storm pumps
- Changes to overall control based on rising level setpoint for storm pumps
- Sanitary pump operation with one pump serving dry weather flow wet well level range in lieu of three
- Sanitary pump speed constraints to maintain operation within AOR
- Changes to number of operating sanitary pumps as a function of wet well level

6.0 Next Steps

The items which require advancement/further development as the design process advances include the following:

- Selected improvements to the operational strategies further detailed and coordinated at greater level of detail within the Design Team.

- Develop table to summarize the storm pump cycling through (turning on) pumps as flow rate increases as part of the control description specification.
- Development of full-scale test plan to evaluate storm and sanitary pump performance when operated in accordance with the selected operational strategy improvements as part of the construction of associated improvements.
- During construction, utilize the full-scale test plan to evaluate pump operation after changes made to storm and sanitary operational strategies to verify modified operations of storm and sanitary pumps provide acceptable performance.
- For storm and sanitary pumps, after future project phases completed and improved operational strategy implemented, tested and tuned, update select sections of the system O&M manual with the new operating procedures. In addition, provide operator training focused on the new operating procedures.
- The sanitary pump operational strategy updates will identify the high moisture alarm condition as basis to take pump out of service and placing another unit in service to allow pump to be removed and inspected to minimize the damage due to moisture intrusion.
- Determine vibration velocity units for the existing sensors (RMS or peak).
- Determine the constraints on the number of vibration signals that the Multilin protection relay can receive as independent signals to potentially allow different limits for top of pump and top of motor.
- After Multilin and vibration switch capabilities verified, discuss vibration alarm and recommended shutdown indication operational practices for the storm pump application with GLWA stakeholders along with the associated operational strategy improvements.
- Confirm bearing temperature, vibration alarm, and trip values with the pump and motor manufacturers.
- GLWA to consider if would like to move forward soon with recommendations to modify sanitary pump strategy changes to enhance service life of the pumps (maximize operation in AOR).
- Complete NPSH calculations for sanitary pumps to confirm that pumps not NPSH limited in the proposed cleaning cycle minimum level (40.2 ft) operating condition.

EXECUTIVE SUMMARY

A physical model study of the Oakwood storm pump station was conducted. A 1:12.1 scale model was constructed, and tests were conducted to determine the nature and severity of any adverse hydraulic conditions that may affect pump performance.

Baseline testing was used to determine minimum operating levels for both the small and large pumps and to evaluate the overall conditions in the wet well and around the pumps. Water level sensitivity testing indicated that when operating a single large pump at full speed, surface dimples were observed at El. 62.0 ft and when operating at minimum speed, surface dimples were observed at El. 61.0 ft. When operating the small pump at full speed, surface dimples were observed at EL. 61.0 ft and when operating at minimum speed, surface dimples were observed at EL. 60.0 ft.

Overall conditions around the pumps were very stable during single pump operation for both the small and large pumps. As the number of operating pumps increased overall conditions became less stable; however, flow still entered each of the operating pumps uniformly around the bell circumferences. A previous model study recommended both floor splitters as well as sidewall fillets for vortex suppression. These were installed for baseline testing and were effective at preventing floor vortex activity and minimizing sidewall vortex activity. Mild and infrequent vortex activity was still observed occurring on the sidewalls but typically flushed out or dissipated prior to or entering the pumps. In addition, when adjacent pumps were operating, mild interaction / swirl was observed forming in between the pumps but no organized vortices were observed. Velocity and turbulence variations as well as pre-swirl were within criteria for all baseline conditions. After submittal of the initial minimum water levels, CDM Smith further revised the final wet well operating levels, based on the initial findings. Final documentation tests were later used to document conditions at revised operating levels as well as to determine if there are any sensitivities related to non-uniform or skewed flow in the influent pipes.

After evaluating conditions with the pumps operating, CEH simulated the existing flushing system. It should be noted that spray and sediments will not scale precisely in the physical model but it does provide a reliable approach to evaluate relative differences and the impact of changes. This testing showed that the effectiveness of the flushing system could be improved by lowering the nozzles from the current elevation to just above the sidewall fillets and placing additional nozzles on the opposite (low flow trench) side to clean the “backside” of the splitters where the nozzles on the opposite side cannot reach.

It is recommended that the pump-off level for the large pumps be set at El. 62.5 ft and the minimum pump-off level for the small pump be set at El. 61.0 ft. The effectiveness of the flushing system can likely be improved by lower the elevation of the flushing nozzles and strategically placing the nozzles relative to the floor splitters. This is discussed in Section 5.5 of this report.

1.0 INTRODUCTION

1.1 Revision 1 – April 7, 2023

Editorial comments addressed per CDM report review. Fig 3-2 was revised to include an updated dimension.

1.2 Background

Clemson Engineering Hydraulics, Inc. (CEH) conducted a physical hydraulic model study of the Great Lakes Water Authority (GLWA) Oakwood Storm Pump Station for CDM Smith and the GLWA. The existing pump station houses both dry-weather and wet-weather pumps. Flow enters the facility via two large sewers (one existing; one future) that combine in a common junction chamber. Two parallel 18-ft diameter influent pipes take flow from the junction chamber to two symmetrical wet wells (East and West) that both house four (4) wet weather pumps including three large pumps rated at 275 CFS and a smaller 150 CFS pump. Dry weather flows can pass through the wet wells via a low flow trench to a sanitary pump station located in a separate downstream chamber. While the low flow trench geometry was simulated, the dry-weather pumps were not included in this study.

1.3 Objectives

The objectives of this model study were as follows:

- Evaluate the performance of the existing pump intake and determine minimum operating levels based on potential air entrainment.
- Evaluate the performance of the wet well flushing system and determine if any revisions or modifications would increase flushing performance.
- Evaluate the intake over the range of expected pump operating combinations and water levels.

1.4 Sump Hydraulics & Pump Problems

The pump manufacturer typically develops pump curves at the manufacturing facility. The head-flow curves, efficiencies, net positive suction head, and power requirements are usually determined by conducting a pump test with the actual prototype pump or a geometrically similar model. This pump test is conducted in a controlled environment with uniform approach flow to the pumps. Therefore, to ensure that the pump will perform as tested at the manufacturing facility; the prototype field installation must also have similarly uniform approach flow conditions.

Failure to provide uniform approach flow hydraulics can result in pump performance that differs significantly from that predicted from the performance curves. The pump may not operate at its best efficiency point, flow or head may be less than expected, power requirements may vary, and if the approach flow conditions vary enough, significant damage could occur to the pump itself.

Pump intakes are often designed to adhere to the 2018 Hydraulic Institute Standards (ANSI HI 9.8-2018). A consortium of pump manufactures, engineers, and end users developed these standards. Failure to adhere to these standards can lead to a number of problems including air entrainment, vortex activity, skewed velocity distributions and turbulence at the pump impeller. Research has shown that these conditions can lead to fluctuating loading on pump impellers, vibration, cavitation, and decreased flow and efficiency (Sweeney and Rockwell 1982).

Following the HI standards helps to minimize adverse approach flow conditions within the pump sump. However, the standards were developed for pumps with individual capacities of 40,000 gallons per minute (gpm) or less for vertical pumps, 20,000 gpm or less in trench type wet wells, 7,000 gpm or less for “can” pumps and 5,000 gpm or less for pumps in circular wet wells. When dealing with pumps that exceed these capacities, or overall station capacities in excess of 100,000 gpm, it is necessary to utilize physical and numerical modeling techniques to investigate the hydraulic conditions within the sump.

Physical models are used to evaluate the level of temporal velocity fluctuations, or turbulence, within the pump bell. Changes in pressure are directly related to changes in velocity. Therefore, velocity fluctuations, whether temporal, or as a result of skewed approach flow, can cause pressure fluctuations on the pump impeller. These pressure fluctuations translate into a loading imbalance on the pump shaft, possibly causing vibration or pre-mature bearing wear.

Physical models are also used to evaluate the uniformity of the flow within the pump bell. Should more flow be traveling down one side of a pump bay than the other, such as that which occurs when there is flow separation at the bay entrance, the velocity may be higher on one side of the impeller or the other. This may cause pre-swirl of the flow entering the pump. Depending on the direction of the pre-swirl relative to the pump rotation, this may cause the pump to consume more or less power than anticipated, resulting in the pump operating at a point other than its best efficiency. The pre-swirl may also result in the flow hitting the impeller blade at an angle of attack other than what it was designed for. This can result in localized flow separation on the impeller. These separation zones can cause low-pressure regions, which result in localized areas of cavitation.

Vortices are another hydraulic phenomenon with which physical models are used to identify and eradicate. Vortices are localized regions of high velocity swirling flow. The velocity at the core of a vortex can be high enough that the pressure falls below the vapor pressure of the fluid. If the vortex forms below the surface, it is called a submerged vortex, and can result in vapor being pulled out of suspension. If it forms as a surface vortex, it can pull a vapor core into the pump. Either of these vortices can result in air entrainment or cavitation within the pump. Depending on the system, this entrained air may be able to accumulate within the downstream piping network, possibly causing damage to other system components. The low-pressure core of a vortex can also lead to localized cavitation, noise, decreased pump capacity, and vibration.

Numerical modeling of pump sumps is a relatively new approach to investigating wet-well hydraulics. The ability of numerical models to predict the general flow patterns within the sump is constantly improving. However, numerically modeling highly mobile surface vortices presents a challenge. Research is constantly being conducted to improve the ability to numerically predict mobile vortex activity. However, at the present, physical models remain the only method available to reliably simulate mobile prototype vortex activity.

2.0 MODEL SCALING AND ACCEPTANCE CRITERIA

2.1 Model Scaling

To obtain accurate results from a physical model study, there must be dynamic similitude between the model and the prototype. To satisfy this requirement, there must be exact geometric similitude. In addition, the ratio of the dynamic pressures must also be maintained. Strictly satisfying dynamic similitude requires a 1:1 scale model. This is usually not feasible, so some compromise is made. To accomplish this, geometric similarity is maintained and the dominant forces associated with the prototype are determined and maintained between the model and prototype.

The primary forces that affect fluid flow are viscosity, surface tension, velocity (inertial), pressure, gravity and elastic forces. In structures with a free surface, such as a pump intake, gravitational and inertial forces are far greater than the viscous and turbulent shear forces. Therefore, when modeling free surface structures, geometric similarity and the ratio of inertial to gravitational forces, or the Froude number, is maintained between the model and prototype.

Simply holding the Froude number constant violates the strict definition of dynamic similitude. However, if the model is operated within a high enough range of Reynolds numbers, viscous and surface tension scale effects may be minimized. The 2018 ANSI-9.8 Hydraulic Institute Standards recommends that the minimum Reynolds number at the pump inlet be greater than 6×10^4 . Therefore, when choosing the model scale, it is necessary to ensure that the scaled flow rate will result in a high enough Reynolds number to minimize scale effects. It is common to be conservative and select a scale that results in a Reynolds number closer to 1×10^5 .

Upon selecting an appropriate model or length scale, it is possible to determine relationships such as velocity, flow, and pressure between the model and prototype. This is accomplished by setting the model and prototype governing equations equal to one another. As mentioned above, the governing equation is determined by evaluating the dominating forces. These equations are typically dimensionless numbers such as the Froude, Reynolds, Weber, Euler, or Mach numbers. These common modeling relationships are shown below:

$$\text{Froude Number} \quad F = \frac{U}{\sqrt{gL}} = \frac{\text{Inertial Force}}{\text{Gravity Force}} \quad (2-1)$$

$$\text{Reynolds Number} \quad Re = \frac{UL}{\nu} = \frac{\text{Inertial Force}}{\text{Viscous Force}} \quad (2-2)$$

$$\text{Euler Number} \quad E = \frac{\rho U^2}{\Delta P} = \frac{\text{Inertial Force}}{\text{Pressure Force}} \quad (2-3)$$

$$\text{Weber Number} \quad W = \frac{U}{\sqrt{\sigma/\rho L}} = \frac{\text{Inertial Force}}{\text{Surface Tension Force}} \quad (2-4)$$

$$\text{Mach Number} \quad M = \frac{U}{\sqrt{K/\rho}} = \frac{\text{Inertial Force}}{\text{Compressive Force}} \quad (2-5)$$

Where:

U = characteristic velocity

g = gravitational constant

L = characteristic length

ρ = fluid density

ΔP = pressure difference

ν = kinematic viscosity of the fluid

σ = surface tension of the fluid

K = bulk modulus of elasticity of the fluid

If the governing equation is held constant between the model and prototype, the corresponding model flow rate, velocity, pressure, etc., can be solved directly. For example, setting the Froude number of the model equal to the prototype yields the following relationships, where the subscripts p & m denote prototype & model, respectively:

$$F_p = F_m \quad (2-6)$$

$$\frac{U_p}{\sqrt{gL_p}} = \frac{U_m}{\sqrt{gL_m}} \quad (2-7)$$

Using equation 2-7, the model velocity, and therefore, the flow rate Q can be solved for if the prototype velocity and length ratio is known. Typically, the model parameters are solved for based on the prototype to model length ratio, L_p/L_m , or L_R . Doing so yields the following equations for Q & U :

$$\frac{Q_p}{Q_m} = L_R^{5/2} \quad (2-8)$$

$$\frac{U_p}{U_m} = \sqrt{L_R} \quad (2-9)$$

Using these equations, it is possible to determine the flow rates at which the model should be operated. The Oakwood model was constructed at a 1:12.1 scale. The resulting model pump bell

Reynolds numbers and Weber numbers for both the large and small pump are shown in the table below.

Pump Size	Reynolds No.	Weber No.
150 cfs	8.4×10^4	600
275 cfs	1.1×10^5	820

All values exceed Hydraulic Institute criteria.

2.2 Acceptance Criteria

In addition to choosing an appropriate scale with which to construct the model, it is important to evaluate the performance of the model against a set of pre-determined acceptance criteria. The criteria used for this model study closely follow those suggested in the 2018 ANSI-9.8 Hydraulic Institute Standards and are as follows:

- No organized free surface or submerged vortices greater than a Type 1 (general rotation) should be permitted at Froude scaled flow rates. The HI standards suggest that a Type 3 vortex may be allowed to enter the pump if it occurs infrequently, such as less than 10-percent of the time; however, it is a goal of this study to eliminate any vortex greater than a Type 1.
- Pre-swirl should be less than 5.0-degrees at the pump impeller location per Hydraulic Institute.
- Time averaged velocities within the pump throat should not deviate more than 10 percent of the cross-sectional area average velocity.
- Time-varying velocity fluctuations (turbulence) at a point within the pump throat should be less than 10 percent.

Vortex activity is evaluated qualitatively. The Hydraulic Institute Standards suggest using a scale of 1 to 6 to rank the severity of a vortex. A scale of 1 to 5 was utilized for this study, with a Type 1 being the least severe and a Type 5 being the most severe, pulling air and trash into the intake. HI varies slightly by ranking a vortex that pulls trash into the intake as a Type 5 and one that pulls air as a Type 6. However, since the acceptance criteria do not permit vortices greater than a Type 1, this variation of the HI scale does not have any effect on the outcome of the model study. Figure 2-1 presents a graphical representation of the vortex ranking used in this study.

3.0 THE MODEL

3.1 *Model Boundaries*

When evaluating the portions of the pump station that are to be included in the model, it is necessary to include any components that could affect the approach flow to the pumps. This is first determined by evaluating the upstream and downstream controls. In this application, an upstream hydraulic control is a structure or component that controls the downstream flow. This may be a change in grade that results in critical flow, a sluice gate or opening that directs the flow, or simply a long stretch that results in uniform flow conditions. The Oakwood pump station consists of two separate mirrored wet wells that each receive flow from a common junction / splitter box that is supplied via two 120-inch influent pipes. A portion of the length of each of these influent pipes were included in the model and served as the upstream model boundary. Flow from the splitter / junction box enters into the separate wet wells (with no cross-over) via individual 216-in (18-ft) diameter supply pipes. The full geometry of the junction / splitter box including both 216-in supply pipes were included in the model. Given the symmetrical nature of each wet well, only one (East Wet Well) was simulated in detail, including all internal geometrical features and all four pumps (1 small and 3 large). The outer geometry of the other wet well was constructed and used to house simple withdraw lines to simulate operation.

Physical model studies are used to evaluate the approach flow and ensure that the flow is uniform up to the pump impeller. Therefore, the downstream model boundary was chosen as the entrance to the pump impeller. It is not necessary to include a model pump impeller because the pump performance is tested at the manufacturer's facility. The manufacturers test was conducted with uniform approach flow conditions. Therefore, with other design considerations being equal, if those conditions can be duplicated in the prototype structure, the performance of the pump in the field should match that determined by the manufacturer.

3.2 *Model Construction*

The model was constructed on a raised deck to facilitate viewing and data collection. The model head box, floor, and sidewalls were constructed with waterproof wood. The model pumps, intake piping and pump bells were fabricated out of clear acrylic up to the impeller location. The additional piping was fabricated out of PVC pipe. Friction losses within the model limits are negligible when compared to form or boundary losses. Therefore, it is assumed that materials mentioned above were appropriate for model construction.

The overall model basin was constructed with a tolerance of +/- 6.3 mm (0.25 model inches). The model pumps were constructed to within +/- 1.5 mm (0.06 model inches). Valves were used to control the individual pump flows as well as the total model flow. A pump was installed downstream of the model pumps to re-circulate flow back to the model head box. Flow straightening devices were installed in the model head-box to ensure that flow entering the head box was uniform. The following figures and photos show the model.

4.0 INSTRUMENTATION AND TESTING PROCEDURES

4.1 Instrumentation and Data Collection

The individual model pump flow rates, as well as the total model flow rate were determined with an ASME standard orifice meter with an accuracy of +/- 2 percent or better. U-tube manometers as well as a Dwyer Series 475 differential manometer were used to measure the manometer deflection. Valves were adjusted in the model piping until the manometer deflections indicated that the proper flow rates were set.

The water levels in the pump sump were recorded with a staff gauge referenced to the sump floor with an accuracy of 3-mm (0.01-ft) or better). Vortex formation was visually observed. Dye was used to aid in the visualization of vortex formation. Vortex strength was rated according to the scale presented in Figure 2-1. Digital photographs and video footage were also used to document vortex formation.

Velocity fluctuations and turbulence levels were measured in one model pump, just upstream of the pump bell. A free spinning miniature propeller Model 412 Nixon Streamflow probe was used to measure the velocities. A data acquisition board was connected to the Nixon probe and recorded approximately 9000 samples over a 30-second period. The software program HPVEE was used to record this data and determine the mean and standard deviation of the velocity data. The pump bell was attached to a turn-column, which allowed the velocity probe to be rotated 360 degrees. Velocities were collected at 8 points around the pump bell, at a fixed radius, in 45-degree increments.

A swirl meter was installed in each pump located four (4) throat diameters downstream of the prototype impeller location (per HI) to measure the level of pre-swirl of flow entering the pump. Each swirl meter consists of 4 straight vanes mounted on a shaft. The swirl angle can be calculated with the following equation:

$$\theta = \tan^{-1} \left(\frac{\pi d n}{u} \right)$$

Where: u = average axial velocity

d = diameter of the pipe in which the swirl meter is installed

n = revolutions per second of the swirl meter

4.2 Test Program

Testing is conducted in three phases, baseline, modification, and final documentation testing. Each of these phases is described below:

- Baseline Testing: Tests were conducted with the intake structure design. These tests were conducted to evaluate the approach flow conditions, and to determine if any adverse hydraulic phenomena were present. In general, vortex activity, pre-swirl, velocity distribution, turbulence levels, and overall approach flow conditions were evaluated.
- Modification Testing: No modification testing was required or conducted for this model.
- Final Documentation Testing: Final testing was conducted to document conditions at the recommended minimum water levels and to evaluate the impact (none observed) based on non-uniform or skewed approach flow in the influent pipes.

5.0 TEST RESULTS

5.1 *Baseline Testing*

Baseline tests were conducted for the original design with several possible operating conditions. In general, the following observations were made:

1. Baseline testing was used to determine minimum operating levels for both the small and large pumps and to evaluate the overall conditions in the wet well and around the pumps.
2. Water level sensitivity testing indicated when operating a single large pump at full speed, surface dimples were observed at El. 62.0 ft and when operating at minimum speed, surface dimples were observed at El. 61.0 ft. When operating the small pump at full speed, surface dimples were observed at EL. 61.0 ft and when operating at minimum speed, surface dimples were observed at EL. 60.0 ft.
3. Overall conditions around the pumps were very stable during single pump operation for both the small and large pumps. As the number of operating pumps increased overall conditions became less stable; however, flow still entered each of the operating pumps uniformly around the bell circumferences.
4. A previous model study recommended both floor splitters as well as sidewall fillets for vortex suppression. These were installed for baseline testing and were effective at preventing floor vortex activity and minimizing sidewall vortex activity. Mild and infrequent vortex activity was still observed occurring on the sidewalls but typically flushed out or dissipated prior to or entering the pumps. In addition, when adjacent pumps were operating, mild interaction / swirl was observed forming in between the pumps but no organized vortices were observed.
5. Velocity and turbulence variations as well as pre-swirl were within criteria for all baseline conditions.
6. After submittal of the initial minimum water levels, CDM Smith further revised the final wet well operating levels, based on the initial findings. Final documentation tests were later used to document conditions at revised operating levels as well as to determine if there are any sensitivities related to non-uniform or skewed flow in the influent lines.

A summary of the baseline data is shown in Table 5-1.

Table 5-1 Baseline Data Summary

Note: See Figure 3-1 for pump orientation. A velocity probe was installed in Pumps 2 and 8. Pre-swirl meters were installed in all four pumps. Velocity and turbulence levels should be less than 10%, pre-swirl should be less than 5.0-degrees, and no vortices greater than Type 1 or weak Type 2 should enter the pump.

Floor splitters and sidewall fillets were installed for all baseline testing.

5.2 *Modification Testing*

Baseline testing showed infrequent sidewall vortex activity forming; however, these were infrequent, weak Type 2 (per our Figure 2-1), typically dissipated as they entered the pumps and did not result in out of criteria turbulence values. Velocity and turbulence variations, as well as pre-swirl values were within criteria for all baseline tests. Based on this, no additional modifications or revisions are required or recommended.

5.3 *Witness Testing*

No formal witness test was held for this model. Video of baseline testing will be included with the final report.

5.4 *Final Documentation Testing*

After submittal of the initial water level recommendations, CDM Smith further revised the levels to be utilized as minimum / pump off levels. These water levels were incorporated into the final documentation testing phase. In addition, final documentation tests were used to determine if conditions in the wet wells were sensitive to skewed or non-uniform flow in the influent pipes that would result from curvature or bends in the pipes upstream of the intake. The following water levels were used as the minimum operating levels for the final testing:

- Small pump minimum operating level (any speed): El. 61.0 ft
- Large pump minimum operating level (any speed): El. 62.5 ft

Table 5-2 shows the final documentation test data.

5.5 *Flushing System Testing*

After evaluating conditions with the pumps operating, CEH simulated the existing flushing system. It should be noted that spray and sediments will not scale precisely in the physical model but it does provide a reliable approach to evaluate relative differences and the impact of changes.

The Oakwood Storm Pump Station flushing system consists of a horizontal pipe that runs along one wall (opposite the low flow trench) with a series of nozzles directed downward. The flushing system is broken down into four quadrants with two in the East Wet Well and two in the West Wet Well. Only one quadrant will operate at a time at a flow rate of 1770 gpm spread out over 11 nozzles. CEH simulated the existing flushing system by scaling the pipe and flowrates at the model scale. The nozzles were approximated with 40-degree spray patterns. One quadrant was operated at a time and simulated 1770 gpm.

To evaluate the general effectiveness the bottom of the wet well was loaded with a layer of crushed walnut shells. The existing flushing header and nozzles were simulated at the existing location and one of the two quadrants in the detailed wet well was operated for a period of time and then the second quadrant was operated. The tests were done with the water level up to the pump bell elevations and then repeated with an empty wet well. In summary, the spray nozzles were not effective at all when there was standing water in the wet well. With no water in the wet well, the existing nozzles were still only minimally effective as the spray spreading out and losing much of its concentrated energy before it reached the sediment.

A second test set of tests were done using a second flushing system, installed on the opposite side of the wet well but at a much lower (just above the existing side wall fillets) elevation. This testing showed a significant improvement over the existing system simply because the lowered nozzle elevations allowed for the energy to remain more concentrated before it impacted the sediment. Given the model observations, the following is recommended.

- 1) On the side with the low flow trench, it is recommended to lower the nozzles to just above the sidewall fillets (approximately El. 55.5-ft) with the spray directed to hit the toe of the splitters below the pump bells. A 40-degree wide spray angle and flat (thin rectangular) pattern was effective.
- 2) On the side opposite the low flow trench, it is recommended that the nozzles also be set at approximately El. 55.5-ft to match the elevation and mirror the spray angle of the nozzles on the side with the low flow trench. Two nozzles should be equally spaced ($1/3$ and $2/3$) the length of each pump's floor splitter and then one nozzle centered between the splitters to push debris through the openings.
- 3) It is also recommended that on the side housing the low flow trench, two nozzles should spray onto each splitter at $1/3$ and $2/3$ the length. This side should not have one centered on the opening as this will simply push sediment to the opposite side. This will help to move sediment on the "backside" of the splitters that the nozzles on the opposite side cannot reach.

The photos below show the qualitative and relative results. Video has also been provided and is considered to be an integral part of this report.

6.0 CONCLUSIONS & RECOMMENDATIONS

6.1 *Conclusions*

Baseline testing was used to determine minimum operating levels for both the small and large pumps and to evaluate the overall conditions in the wet well and around the pumps. Water level sensitivity testing indicated that when operating a single large pump at full speed, surface dimples were observed at El. 62.0 ft and when operating at minimum speed, surface dimples were observed at El. 61.0 ft. When operating the small pump at full speed, surface dimples were observed at EL. 61.0 ft and when operating at minimum speed, surface dimples were observed at EL. 60.0 ft.

Overall conditions around the pumps were very stable during single pump operation for both the small and large pumps. As the number of operating pumps increased overall conditions became less stable; however, flow still entered each of the operating pumps uniformly around the bell circumferences. A previous model study recommended both floor splitters as well as sidewall fillets for vortex suppression. These were installed for baseline testing and were effective at preventing floor vortex activity and minimizing sidewall vortex activity. Mild and infrequent vortex activity was still observed occurring on the sidewalls but typically flushed out or dissipated prior to or entering the pumps. In addition, when adjacent pumps were operating, mild interaction / swirl was observed forming in between the pumps but no organized vortices were observed. Velocity and turbulence variations as well as pre-swirl were within criteria for all baseline conditions. After submittal of the initial minimum water levels, CDM Smith further revised the final wet well operating levels, based on the initial findings. Final documentation tests were later used to document conditions at revised operating levels as well as to determine if there are any sensitivities related to non-uniform or skewed flow in the influent lines.

After evaluating conditions with the pumps operating, CEH simulated the existing flushing system. It should be noted that spray and sediments will not scale precisely in the physical model but it does provide a reliable approach to evaluate relative differences and the impact of changes. This testing showed that the effectiveness of the flushing system could be improved by lowering the nozzles from the current elevation to just above the sidewall fillets and placing additional nozzles on the opposite (low flow trench) side to clean the “backside” of the splitters where the nozzles on the opposite side cannot reach.

6.2 *Recommendations*

It is recommended that the pump-off level for the large pumps be set at El. 62.5 ft and the minimum pump-off level for the small pump be set at El. 61.0 ft. The effectiveness of the flushing system can likely be improved by lower the elevation of the flushing nozzles and strategically placing the nozzles relative to the floor splitters. This is discussed in Section 5.5 of this report.

*Subject: TM-22 Flushing Systems (Leib-FD-1, OKW-FD-2 and OKW-PUMP-1B)
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) reviews the work studies/evaluations to develop the design of work that will improve the flushing systems at the Leib CSO Screening and Disinfection Facility (SDF), the Oakwood CSO Retention Treatment Basin (RTB), and for the Oakwood Storm Wet Well flushing systems. The goal of this work is to make improvements to the flushing systems that will reliably and simply reduce the Great Lakes Water Authority (GLWA) staff's time and effort required to clean and clear residuals after storm events in the facilities. The proposed improvements will improve on the safety of the staff and the operations and maintenance (O&M) activities required.

Leib SDF Recommendations

- The following improvements are recommended to provide a better means of flushing the screening inlet channels in the Screening Chamber after wet-weather events in the Leib SDF.
 - A piped service water main is to be installed to deliver water volume and spray area to the screening inlet channel. Additionally, a pipeline is recommended to be provided at the head end of the screening collection channel.
 - The stepped floor within the screening inlet channels are to be topped with a concrete coating to make the surface smooth.

Oakwood CSO RTB Recommendations

- The following improvements are recommended to make the flushing valves in the Oakwood CSO RTB more accessible for maintenance.

- The service water mains and valves in the Oakwood CSO RTB are to be relocated downstream of the flushing gates.
- The following improvements are recommended to provide a means to keep the Oakwood CSO RTB sumps and basin drain piping clean of debris that may result in issues draining the basin.
 - The addition of a conditioning pump that is specifically manufactured to recirculate sanitary flows is to be included within each sump. These pumps will operate during times where there is a sufficient depth of fluid in the sumps.
 - A new service water flushing header is to be routed from the existing lines to each sump. The ability to add clean, clear water to the flushing media will increase the conditioning pump's ability to keep the media suspended.

Oakwood Pump Station Storm Wet Well Recommendations

- For Oakwood storm wet well flushing system the following improvements serving each wet well are recommended:
 - Lower existing downstream header (located beside storm pumps) and direct discharge on top of the "short" sidewall fillet at elevation high enough to establish spray pattern and minimize gap between adjoining nozzle discharges.
 - In vicinity of storm pumps, add header on sanitary flow trench side of wet well. Mount above sidewall fillet, spray pattern to contact the toe of the splitter below each pump bell. Provide new isolation valve near other isolation valves on intermediate level dedicated to new header to facilitate automated or manual control from Ovation workstation.
 - Lower existing upstream header to elevation set to achieve intended spray pattern above top of expansion zone sloped concrete floor slab at upstream end of system where nozzles will be closest to floor slab.
 - Replace all nozzles with units providing 40–65-degree spray angle with a flat (even) spray pattern.
 - Maintain approximately the same number of nozzles in each zone of the flushing system to provide similar demand on the secondary water system as compared to existing wet well zones, unless selected per nozzle flow rate allows greater number.
 - Remove all sanitary flow trench covers in storm wet well to maximize trench length over which debris can be conveyed into trench and avoid debris accumulation on covers.

Description of Leib SDF Flushing System

The Leib SDF does not have a flushing system for the Screening Chamber beyond service water hose bibs located along the catwalks over the facility Influent Channel and the screening chamber. The area that is most problematic is the “stepped” sloped floor within the screening inlet channel and the screening collection channel. These areas receive the largest volume of debris after a wet weather event and have the highest concentration of the screenings.

Spray down and water distribution systems were reviewed, and two main recommendations have been identified. First the “stepped” sloped floor should be topped with a concrete coating to make the surface smooth. This will aid in the flow of the debris to the dry weather flow channel during dewatering. To aid in the effort and to reduce in the manual need to spray the area down, a piped service water main is proposed to deliver water volume and spray area to the screening inlet channel. Additionally, a pipeline is recommended to be provided at the head end of the screening collection channel.

Description of Oakwood CSO RTB Flushing Valves and Flushing System Improvements

The Oakwood CSO RTB has flushing water service pipelines that deliver water to the flushing gate reservoirs. The valves on these lines are located under the roof slab and are difficult to access for maintenance. The service water mains and valves are proposed to be relocated further into the basin at a location that can be more safely accessed.

The flushing gates transfer debris that has collected on the basin floor after dewatering. This debris is pushed to a collection channel that is dewatered through an 8 ft by 8 ft sump. There are two sumps (one per basin) and each sump has two drains that transfer dewatered flow and debris to either the sanitary gravity main or back to the upstream. High concentration of sludge and debris in the sumps have proven to be problematic and difficult to clear if the lines plug. GLWA has identified that only the lower drain, to the upstream junction chamber, has historically plugged. Several alternatives of methods to resuspend or keep suspended the debris in the sumps were researched. Two improvements are identified in this TM. The addition of a conditioning pump that is specifically manufactured to recirculate sanitary flows is proposed to be included within each sump. These pumps will operate during times where there is a sufficient depth of fluid in the sumps. This activity will lessen the potential of the drains clogging. To aid in the effort to improve on the concentrated flushing fluid’s ability to flow within the gravity drains, a new service water flushing header will be routed from the existing lines to each sump. The ability to add clean, clear water to the flushing media will increase the conditioning pump’s ability to keep the media suspended, and it will also be used to flush down the pipelines after flushing activities.

Oakwood Storm Wet Well Flushing System

The Oakwood storm wet well flushing system improvements evaluation was focused on assessment of the usefulness and operability of the existing system and to propose improvements to the system to aid in increased use and effectiveness. The evaluation of the system was conducted in two

phases, first existing system hydraulic characteristics and second use of a physical model study to assess existing system configuration performance and system modifications to improve flushing functionality.

1.0 Introduction and Purpose

TM-22 is focused on the evaluation of several flushing systems to be added or improved as part of this project. This includes the following:

- Leib SDF Flushing System
- Oakwood CSO RTB Flushing Valves and Drainage Sumps
- Improvements to the existing Oakwood storm wet well flushing system (both storm wet wells)

The TM is configured to first cover the Leib SDF flushing system, followed by the Oakwood CSO RTB flushing valves and drainage sumps, and finally the improvements to the Oakwood storm wet well flushing system within each section.

The Oakwood storm wet well flushing system improvements evaluation was focused on assessment of the usefulness and operability of the existing system and to propose improvements to the system to aid in increased use and effectiveness.

2.0 Existing Systems Description

2.1 Existing Leib SDF Flushing System

The Leib SDF does not have a dedicated system for flushing the screening chamber. The facility presently drains by gravity following storm events. Solids accumulation has not been a major issue due to limited use, with the exception of the screening inlet channels. The screening inlet channels are manually hosed down using city water following an event in which the screens are in use. Manual wash down is performed via hose reels that are located along catwalks above the screening channels. The hose reels are fed by a pipe header that extends down from the upper level of the facility. The facility operator presently uses a smooth bore fire nozzle on the end of the hose reels. This type of nozzle has been more effective than a standard spray nozzle.

The present manual wash down does not present issues in cleaning the facility. However, the process is difficult, time-consuming, and requires two operators to access all areas in need of wash down. Discussion with the Leib facility operator indicated that the present water pressure at the hose reels is adequate enough to perform the wash down, however a higher pressure is desired to wash down more efficiently.

The complete wash down process involves cleaning the screens and screening inlet channels, the influent channel and dry-weather flow trench, the screening outlet channels, and the screening collection channels. There are four screening inlet channels; two of the channels contain vertical

Romag screens, and two of the channels contain horizontal Copa screens. The channels with the Romag screens are easier to wash down as they are open from above and can be sprayed down from the catwalks. The channels with the Copa screens are entirely covered by the screen and are difficult to wash down. To clean the channels with the Copa screens, the operator must go down into the screening collection channel and wash the screen and screening inlet channel through a gate opening in the screening collection channel wall.

Figures 2-1 and 2-2 show a section and plan view of the present 2-inch water line in the Leib SDF. **Figure 2-3** shows the screening inlet channel for the Copa screens.

Figure 2-1
Section View of Existing 2-Inch Water Line in the Leib SDF

Figure 2-2
Plan View of Existing 2-Inch Water Line in the Leib SDF

Figure 2-3
Copa Screening Inlet Channel

The planned area for advanced flushing is the “stepped” area within the screening inlet channel. The channel floor is sloped from the back end of the screening inlet channel to the front end near

the influent dry weather flow channel This is the area with the highest concentration of debris which gets held up on the stepped surface. This surface is also shown in **Figure 2-2** and **Figure 2-3**.

2.2 Existing Oakwood CSO RTB Flushing Gates and Fill Valves

The basins at the Oakwood CSO RTB are primarily dewatered by gravity following use during a wet weather event. At the conclusion of basin dewatering, solids that had settled out of the water remain on the floor of the basin. The Oakwood CSO RTB presently has a flushing gate system in place to handle the removal of these solids. Both the east and west CSO basins utilize eight flushing gates for the basin floor and two for the basin influent channels for a total of twenty flushing gates.

Each flushing gate holds the chlorinated and screened combined sewage in an open flushing reservoir. The flushing reservoirs are filled as the basin is filled during a wet weather event. Flushing water remains in the flushing reservoirs after the basins have been dewatered. The reservoirs remain full until the control logic or Oakwood CSO RTB operators initiate the flushing sequence. The entire stored volume is then released to scour settled solids off the floor and flush the solids to the flushing sumps. This is done in a timed sequence in order to maintain continuous flow to the pump station. If the initial flushing sequence is not satisfactory, the flushing reservoirs may be refilled using the facility's secondary water system, and the flushing sequence is run again.

Secondary water fill valves used to control the additional flushing procedures are located above the influent channels and flushing reservoirs. These valves are on the secondary water lines. There are three secondary water fill valves in each basin, two for the flushing reservoirs and one for the influent channels. The valves are 4-inch motor operated gate valves. The actuators that operate the fill valves are located on the roof of the CSO basin. The actuators are located on the southern end of the basin roof; two actuators are located at each of the east and west edges of the roof, and two actuators are located centrally.

The secondary water fill valves, or flushing valves, are difficult to reach during maintenance activities due to their location over the basin influent channel. presently, scaffolding is set up to reach the valves, and it is difficult to set up the scaffolding due to the steep slope of the basin influent channel.

Figure 2-4 shows the shows the secondary water fill header and valves in the west CSO Basin.

Figure 2-4
Secondary Water Fill Valves for the Flushing Reservoirs (Both) and the Influent Channels (Left)

2.3 Existing Oakwood CSO RTB Sump Flushing

The basins at the Oakwood CSO RTB are primarily dewatered by gravity following use during a wet weather event. Each basin is connected to the “drain to Northwest Interceptor (NWI)” pipe through a “CSO Basin Drain to NWI” control valve. The basins are drained to the NWI until the water surface reaches an elevation of 94.5 feet (elevation may have changed based on operating experience). The remaining volume in the basins is drained back to the Oakwood Pump Station by gravity. A series of valves along the drains to the NWI and the drains to the Oakwood Pump Station regulate the timing of the dewatering operation as well as the dewatering flow rates.

Presently, significant grit accumulation at the flushing sumps is an issue. Grit accumulation leads to plugging of the drain lines leading out from the sumps. Presently, the drain lines are cleared manually by jetting the drains. Frequent jetting of the drain lines is difficult due to the configuration of the pipes below the facility’s slab and the depth to the flushing sump below the adjacent finger weir. An image of one of the sumps is shown in **Figure 2-5** for reference.

Figure 2-5
Sump at Effluent Side of Oakwood CSO RTB

2.4 Oakwood Storm Wet Well Flushing System

The existing Oakwood storm wet well flushing system is configured generally the same way in both wet wells with the flushing water header mounted to the outside wall and equipped with a series of fixed nozzles. The 8-inch header is mounted at CL El 61.5 which is approximately 11-ft above the wet well floor.

This flushing system is arranged with a total of six zones:

- Sanitary flow trench (two zones): Discharge into the sanitary flow trench within the upstream junction chamber (east and west) via outlet of the flushing water pipe (no nozzles)
- Storm wet well upstream (two zones): Discharge to the upstream portion of the wet well including the expansion zone (east and west) as shown in **Figure 2-6**.
- Storm wet well downstream (two zones): Discharge to the downstream portion of the wet well (east and west) as shown in **Figure 2-6**.

The system in the Oakwood Storm Pump Wet Well is represented graphically in **Figure 2-6** as shown in PC-755 record drawing D-04-08-409.

Figure 2-6
Existing Flushing System Section from PC-755 Record Drawings

Each zone is supplied by secondary water with supply on/off controlled by a motorized isolation valve. Only one zone is operated at a time to maximize the effectiveness of the system and to constrain reduction of secondary water system pressure during operation. Refer to Section 3 for the operation of the system.

Each zone of wet well/expansion zone is equipped with a series of nozzles with most directed generally down (20 degrees offset from vertically down) and two directed for horizontal discharge. Upstream zone includes 11 nozzles and the downstream zone includes 10 nozzles.

All nozzles were furnished as part the original construction and appear to be the PC-755 required product: 2-inch full-cone nozzle with 65-degree spray angle, Distribojet Model 2 RR-SS 65 45, manufactured by Spraying Systems Inc. as shown in **Figure 2-7**.

Figure 2-7
Existing Flushing System Nozzle (Oakwood Storm Wet Wells)

3.0 System Evaluation

3.1 Leib SDF Flushing System

A model of the service water system was developed in InfoWater. InfoWater is an advanced software for modeling and managing water distribution networks. This model was used to evaluate the feasibility of the Leib SDF flushing system alternatives. The model was also used to evaluate the need for a high-pressure water tank to provide the desired pressure at the flushing system nozzles. The model was developed with the assumption that the pressure delivered to the Leib SDF is 55 psi. The flushing system was modeled with a conceptual flow rate of 10 gpm through the nozzles and a conceptual minimum pressure of 10 psi at the nozzles.

The alternatives for this system are designed around an extension of the 2-inch diameter headers presently feeding water to the hose bibs in the SDF. Full cone spiral nozzles are to be placed at intervals along the new water line headers to provide complete coverage of the area for the chosen alternative. **Table 3-1** displays the theoretical spray coverage of these nozzles for a given spray angle and distance from the surface. Placement of nozzles along the header is ultimately subject to the header distance from the surface to be sprayed and the water pressure available at the nozzle.

Table 3-1 Theoretical Spray Coverage at Various Distances in Inches (cm) from Nozzle Orifice

Full cone spiral nozzles (**Figure 3-1**) spray water in a solid, cone shaped pattern and offer spray angles ranging from 60 to 170 degrees. Spiral nozzles are also designed to mitigate clogging due to debris buildup.

Figure 3-1
Full Cone Spiral Nozzle

3.2 Oakwood CSO RTB Flushing Valve Relocation

The flushing valves are difficult to reach during maintenance activities due to their location over the basin influent channel. Presently, scaffolding is set up to reach the valves, and it is difficult to set up the scaffolding due to the steep slope of the basin influent channel. To accommodate more convenient maintenance activities, the flushing valves would need to move roughly 50-ft north in the basin to move over the CSO Basin floor. This would allow scaffolding to be set up more easily, as the basin floor has a mild slope.

3.3 Oakwood CSO RTB Sump Flushing/Mixing

Grit accumulation at the flushing sumps has led to plugging of the drain lines leading out from the sumps. The design alternatives considered to resolve this issue center around the idea of introducing a form of positive agitation in the sump to resuspend and keep in suspension grit and sludge that has accumulated in the sump.

3.4 Oakwood Storm Wet Well Flushing System

The evaluation of the storm wet well flushing system focused on the use of two tools: first, modeling one quarter of the wet well system using WaterCAD software and second qualitative evaluation as part of the physical model study.

3.4.1 Evaluation of existing storm wet well flushing system hydraulic characteristics

The storm wet well flushing system hydraulic considerations were evaluated to facilitate estimation of the quantity of water required to operate the wet well portions of the system as presently configured.

WaterCAD model was built to represent the upstream portion of the wet well (one quarter of the system (11 nozzles in lieu of 10 nozzles downstream)) which was assumed to be generally representative of all four quadrants of this system with the common header configuration and slight variations between the quadrants.

Assumptions in the model included the following:

- Sanitary flow trench (two zones): Discharge into the sanitary flow trench within the upstream junction chamber (east and west) via outlet of the flushing water pipe (no nozzles) would be the first step in overall flushing procedure to reduce debris quantity in the sanitary flow trench but this was not included in the model. Assumed sanitary flow trench would be generally clear of debris given frequency of use recommended in section below.
- Distribution system pressure assumed to be between 50 psi and 70 psi (GLWA estimated 65-70 psi per SCC)
- Losses in backflow preventer (10 psi drop); flow meter (10 psi drop – likely conservative) upstream of the flushing system headers

- Nozzles modeled as “D2A” – discharge to atmosphere at a given design flow rate and head.
 - Checked and confirmed that model results were close to manufacturer’s nozzle design manual flow rate values

Hydraulic model results:

For one quarter of the wet well system (only one quarter operates at a time) in operation and distribution system pressure maximized (70 psi at elevation 96-ft in street) the total flow rate was estimated to be approximately 1,940 gpm (2.8 mgd) total with pressure immediately upstream of nozzle in range of 51-52 psi (estimated flow rate of 195 gpm/nozzle) at header CL elevation, 61-ft. This represents the maximum water usage of the system at the maximum operating pressure.

- This pressure immediately upstream of the nozzle was identified to be well above the assumed value for the original design pressure (3 psi).

Based on model results the Design Team concluded that greater loss at the nozzle would benefit the system to reduce overall water usage if cleaning functionality is not impacted.

Other observations from analysis:

The installed nozzle type distributes the spray pattern uniformly over a wide area which does not allow the energy in the flushing water system to be concentrated to effectively push the debris toward the sanitary flow trench. Therefore, an alternate spray pattern which concentrates the flushing system motive energy was evaluated as part of the physical model study.

3.4.2 Evaluation of storm wet well flushing system using physical model study

The physical model study was utilized to qualitatively evaluate the wet well flushing system performance. This was accomplished by comparing the reduced scale model performance of the system at existing mounted elevation (about 11-ft above the floor) to a significantly lower flushing system header (at approximately top of the center wall splitter which is about 4-ft above floor)).

The physical model was utilized to qualitatively evaluate the following:

- Relative performance of higher versus lower flushing water header
 - Lower flushing water header has superior performance as shown in **Figures 3-2 and 3-3** after or just before completion of flush cycle

Figure 3-2
Flushing system ineffective at existing (high) mounting elevation, photo courtesy of CEH

Figure 3-3
Flushing system effective at lower mounting elevation, photo courtesy of CEH

- Strategic placement of the nozzles along the header
 - Placement optimized to minimize debris remaining on wet well floor after flush cycle and convey debris to the sanitary flow trench as shown in **Figure 3-4**
 - On the side opposite the sanitary flow trench, position two nozzles along each pump spaced $\frac{1}{3}$ and $\frac{2}{3}$ of length of splitter and one nozzle centered between the splitters to push debris through the openings between splitters.
 - On the side of the sanitary flow trench, two nozzles positioned along each pump spaced $\frac{1}{3}$ and $\frac{2}{3}$ of length of floor splitter to cover area unreachable by other zone.
 - The targeted nozzle positions will be evaluated relative to the spray pattern reach.

Figure 3-4

Conceptual nozzle location sketch for downstream flushing water headers in east storm wet well, similar in west wet well

- Preferred nozzle spray pattern and angle
 - Spray pattern to be flat (even) with thin rectangular profile at angle of 40-65 degrees. It may be necessary to increase spray angle above 40 degrees to establish nozzle discharge in contact at the point of impact as balance energy conveyed to the debris and reach to the debris within the constraints of the secondary water system.
- Elevation to mount the nozzles to maximize effectiveness
 - On sanitary flow trench side of the wet well, mount above sidewall fillet at elevation to allow spray pattern to contact the toe of the splitter below pump bell.

- On the opposite side, position nozzles to discharge on the top of the “short” sidewall fillet at elevation to establish the intended spray pattern and reach.
- Value of sanitary flow trench cover removal in vicinity of each storm pump bell to enhance opportunity to flush debris into the trench for conveyance downstream
 - The baseline physical model testing demonstrated that no adverse hydraulic conditions caused by the removal of the trench covers to storm pump intake conditions.
 - Benefit to provide maximum open length over which debris can be conveyed into the trench, unobstructed by the covers. In addition, removal of the covers will avoid accumulation of debris as observed in recent wet well entry on the first trench cover as shown in **Figure 3-5**.

Figure 3-5

Debris accumulation on sanitary flow trench cover, photo courtesy of Pullman SST, Inc.

Model study assumptions:

- The number of nozzles will be maintained to be comparable to the existing condition in each zone to minimize the potential to increase the water demand of the system.
- One zone of the system will operate at a time with the upstream portion operating before the downstream portion for in-series cleaning within each wet well.
- Qualitative comparison with the physical size of nozzle/discharge location relative to face of wall not to scale due to limitations of commercially available nozzles.
- At reduced scale, crushed walnut shells approximate the behavior of the grit/sludge/silt which accumulates in the Oakwood wet wells.

3.4.3 Present operation considerations

The present operation of the storm wet well flushing system was evaluated through discussions with operations staff as part of our operation ride-alongs and interaction with the wet well cleaning contractor who was cleaning the wet wells at the time of this writing.

The findings of the evaluation follow:

- The flushing system is not presently utilized frequently.
- Given the “knee high” level of the debris observed in the wet well recently, as evidenced by the contractor’s photo in **Figure 3-6**, the existing system would not be effective to remove this quantity of silt/sediment/sludge (3 + years of accumulation coupled with sanitary flow backup due to sanitary influent screen debris accumulation over part of that time). The debris/sludge characteristics observed by the cleaning contractor (recent activity as part of a separate project) identified a material with high water content and fairly loose consistency which could be waded through.
- Several years ago the system was operated with some level of frequency but the loss of motor operator function on one of the four wet well flushing system isolation valves resulted in reduced level of usage.
- Mixed information received regarding the secondary water system pressure reduction when flushing system in use. One staff member noted no impact while another noted a one-time alarm from the fire suppression system for low pressure (both systems utilize the same source water but separated by backflow preventer).
- Information regarding effectiveness of cleaning if operated after each storm event was not available.

Figure 3-6
Wet Well Debris February 2023, photo courtesy Pullman SST, Inc.

3.4.4 Conceptual operating procedure after system improvements

The following conceptual operating procedure to be conducted after each wet weather event would apply after the flushing system has been optimized as part of this project (nozzle type/angle, number of nozzles, header elevation, etc.) to reduce the required frequency of manual cleaning:

- Procedure applies to east and west systems; complete one side then transition to the other side. The duration of each step will be defined in BOD phase.
- Wet well dewatered using the sanitary pumps to a water surface elevation below the invert of sanitary flow trench (El 47.0) which is 1-ft above the present normal operating level range of the sanitary pumps (El 41 – 46-ft) thus compatible to maintain no ponding water in storm wet well. This step is critical as the model study demonstrated the flushing system does not perform effectively with standing water in the wet well.
- Flushing water added to sanitary flow trench (at upstream junction chamber)
- Flush the upstream portion of wet well
- Flush the sanitary flow trench
- Flush the downstream portion of wet well on side opposite the sanitary flow trench

- Flush the sanitary flow trench
- Flush the downstream portion of wet well on side with sanitary flow trench
- Flush the sanitary flow trench
- Pump down the flushing water/debris using the sanitary pumps after/during each flushing procedure step
- Repeat for the other sanitary flow trench/wet well

4.0 Description of Alternatives

4.1 Leib SDF Flushing System

Both improvement alternatives to the Leib SDF flushing system are based on an extension of the existing header in the facility and the implementation of nozzles to spray water down into the areas with solids accumulation.

4.1.1 Screening Inlet Channel Flushing System

A proposed alternative is to install a new flushing system piped from the existing water line that presently supplies the hose reels. The new flushing system would extend lower into the facility and lie in and above the screening inlet channels where a configuration of nozzles would be located and aimed in a way to provide wash down coverage of the screening inlet channels at the upper end of the “stepped” slope in the channel. **Figure 4-1** highlights the area in the SDF to be flushed in this alternative.

Figure 4-1
SDF Area Flushed in the Automated Flushing System Alternative

To aid further into the effectiveness of the flushing process the “stepped” feature of the sloped inlet channel can be modified to have a smooth surface. A smooth surface will improve the flushing systems ability to wash down debris to the sanitary channel. A section of the slope will need to include a stair section to allow personnel the ability to walk up the channel if needed.

To make the above improvement, the existing stairs would be modified by jackhammer or saw cutting to remove the steps, including the embedded rebars, down to a sloped surface with a surface roughness of approximately CSP7. The contractor would then scarify the surface to the roughness required for the repair mortar to bond. Once the contractor has prepped the surface, new concrete repair mortar will be applied in approximately a 2-inch-thick layer. At the bottom of the ramp a groove would be chipped out to avoid a feather edge at the low point of the ramp. The repair mortar would be troweled smooth to match the desired slope. **Figure 4-2** shows a cross section of the proposed work.

Figure 4-2
Proposed Modifications to the Stepped Feature in the Sloped Inlet Channel

4.1.2 Expanded Flushing System

A second proposed alternative is to expand upon the system described in Section 4.1.1. The same flushing system would be in place over the screening inlet channels. This alternative would expand the flushing system to provide coverage of the influent channel and dry-weather flow trench, the screening outlet channels, and the screening collection channel. This alternative provides an automated flushing system for all areas of the facility that are regularly washed down following storm events. **Figure 4-3** highlights the area in the SDF to be flushed in this alternative.

Figure 4-3
SDF Area Flushed in the Expanded Automated Flushing System Alternative

4.2 Oakwood CSO RTB Flushing Valve Relocation

4.2.1 Relocation of Flushing Valves and Header

A proposed alternative is to relocate the flushing valves and associated actuators to an area downstream of the flushing gates. The recommended relocation of the valves is over the CSO basin floor, which has a mild slope and should not pose issues when setting up scaffolding. Relocation of the valves in the CSO Basin would also require relocation of their respective actuators on the roof of the CSO Basin. This alternative would also require demolition of the existing pipes and installation of new pipes to accommodate the valve relocation. **Figure 4-4** shows a marked-up image of this alternative concept. **Figures 4-5** and **4-6** roughly show the proposed area for the relocation of the valve actuators.

Figure 4-4
Image Markup Showing New Water Line Route and Valves over CSO Basin Floor

Figure 4-5
Image Markup Showing Rough Area of Valve Actuator Relocation (Red Indicates Existing and Green Indicates Proposed)

Figure 4-6
Aerial Markup Showing Rough Area of Valve Actuator Relocation (Red Indicates Existing and Green Indicates Proposed)

4.2.2 Relocation of Flushing Valves and Header, and Flushing Header Extension to Basin Sumps

This proposed alternative is an extension of the previous alternative and contains the same design elements as before. In addition to those proposed changes, this alternative would extend the flushing line towards the sump in both basins. The flushing line would conclude at a header located in the sump. The purpose of the header would be to spray flushing water on the sides of the sump walls to work in tandem with the alternatives presented in Section 4.3 to reduce grit accumulation in the sump. This header would also provide clear water volume to the collection of debris and sludge being flushed from the channels. The header in the sump would operate during the CSO Basin flushing process.

This extension of the flushing line to the basin sumps would also require the addition of two new actuators on the roof of the building to facilitate the control of the flushing water added to the sumps. **Figure 4-7** shows the general location of where these new actuators would need to be placed on the CSO Basin roof to sit atop the basin sumps.

Figure 4-7
Aerial Markup Showing Area of Proposed Sump Pump Hatch Location

4.3 Oakwood CSO RTB Sump Flushing/Mixing

The following alternatives to reduce grit accumulation in the CSO basin sumps will be located in the 8-ft x 8-ft sumps themselves.

4.3.1 Submersible Solids Handling Pumps with Nozzles System

An alternative to mitigate the CSO basin sump pipe clogging issues include installing submersible solids handling pumps at each sump to recirculate effluent near the sump drains and resuspend accumulated materials. A 4-inch ductile iron pump discharge manifold mounted around the sump with two or three nozzles pointed toward the sump opening would support particulate resuspension while the basin is use.

As the facility comes into operation, the pumps would start operating and continue operation for the duration of the event and as the facility is drained. By preventing a large accumulation of grit at the sump, the draining process can more effectively dewater the facility and gradually remove settled materials. Pumps would be rail-mounted and removable to the surface through new hatched openings in the top of the structure.

A submersible solids handling pump will have estimated electrical demands of 5 HP, 480 Volts, 60 Hz, and 3-phase.

Figure 4-8 shows a plan view of the submersible solids handling pump alternative in the CSO Basin sump.

Figure 4-8
Plan View of the Submersible Solids Handling Pump with Nozzles System in the Basin Sump

4.3.2 Conditioning Sump Pumps with Direct Nozzle

Another alternative to mitigate the pipe clogging includes installing submersible conditioning sump pumps at each sump to recirculate effluent near the sump drains. The conditioning pumps would chop and mix accumulated materials to prevent clumping and clogging of grit in the sump drainpipes.

As the facility comes into operation, the pumps would start operating and continue operation for the duration of the event and as the facility is drained. By preventing a large accumulation of grit at the sump, the draining process can more effectively dewater the facility and gradually remove settled materials.

A conditioning sump pump will have estimated electrical demands of 15 HP, 480 Volts, 60 Hz, and 3-phase. **Figure 4-9** shows a plan view of the conditioning sump pump alternative in the CSO Basin sump.

Figure 4-9
Plan View of the Conditioning Sump Pump with Direct Nozzle System in the Basin Sump

4.3.3 Air Induction Units to Generate Particle Suspension

A third alternative evaluated is an air induction unit (commercial brand Wet Well Wizard™). The air induction unit is a wet well aeration system with no moving parts and utilizes no electricity underwater. This technology consists of a set of antipodal bubble cleaving disks inside a confined tube that cuts and shapes large air bubbles into high speed, spinning “FOG cutters.” The ejection of a continuous flow of cleaved spinning bubbles into the wet well water breaks up and liquefies FOG and other viscous semi-solids. The only maintenance required is cleaning an air filter occasionally.

The manufacturer claims that the device will not become clogged with floating well debris. The air source is an industrial grade regenerative blower.

The air induction unit would operate as the CSO basin fills and dewateres. During these times, air would be continuously pumped into the bottom of the sump to mix up the screened wastewater and prevent solids from settling out.

An air induction unit will have estimated electrical demands of 3 HP, 480 Volts, 60 Hz, and 3-phase.

Figure 4-10 shows a plan view of the air induction units alternative in the CSO Basin sump.

Figure 4-10
Plan View of the Air Induction Unit System in the Basin Sump

4.3.4 Gravity Line Clean Out

Common to all alternatives is the addition of clean out access lines on each gravity pipeline. The cleanouts will be located outside of the basin. These clean out lines will be accessed to snake the lines back toward the sump. Access to the cleanouts will be below the basin hydraulic grade line during wet weather events, therefore the connections need to be flanged for secure isolation from the hydraulic pressure within the basin. This service access provides a more accessible location, safer connection point, and is non-disruptive to the existing basin facility.

There are two options for locating the clean outs. The first option is to locate the clean outs within the valve chambers. The second option is to locate the clean outs between the valve chamber and the CSO Basin where a new connection can be added to the gravity line and brought to grade.

4.3.5 Flushing Header Extension to Basin Sumps

This section is redundant of Section 4.2.2, and a more detailed description of it can be found there.

This alternative would extend the flushing line towards the sump in both basins. The flushing line would conclude at a header located in the sump. The purpose of the header would be to spray flushing water on the sides of the sump walls to work in tandem with the alternatives presented earlier in this section to reduce grit accumulation in the sump. This header would also provide clear water volume to the collection of debris and sludge being flushed from the channels. The header in the sump would operate during the CSO Basin flushing process.

4.4 Oakwood Storm Wet Well Flushing System

Not used.

4.5 Alternatives Evaluation Criteria

Each recommendation reviewed in the alternatives were evaluated on the following criteria based on the GLWA CSO Improvement Project Guiding Principles.

- Increase operational flexibility for GLWA staff.
- Decrease amount of time require by staff for manual wash down and debris removal.
- Improve staff safety by reducing frequency of entrance to facility basins and SDF areas.
- Provide better access to equipment for maintenance.

5.0 Alternatives Analysis

5.1 Leib SDF Flushing System

5.1.1 Screening inlet Channel Flushing System

This alternative would address the issue of solids accumulation within the screening inlet channels. It would assist the Leib SDF operator in routine cleaning of the facility after storm events where the screens see use and cut down on time needed to manually clean the facility. Spray down from the catwalk areas will still be needed but the main area of the screening inlet will have the flushing system available through a valved piping connection.

Providing a flushing system for the screening inlet channels may prove to be difficult in providing complete coverage for both existing screen types and a proposed third screen type. However, this challenge is not unique to this alternative.

5.1.2 Expanded Flushing System

This alternative would provide the same services as the previous alternative but on a larger scale. This alternative would further reduce the time needed to manually clean the facility after screening and disinfection events by providing flushing water for even more areas of the facility.

Some of the areas, especially the screen faces and other remote sections of the facility, would require an extensive and complicated arrangement. The extended system would not eliminate the needs for manual spray down from the catwalk access as is done now.

This also would encounter the same challenge of designing a flushing system that provides complete coverage for each unique chamber given the different types of screens. This alternative would have a much more involved design than the previous alternative.

5.2 Oakwood CSO RTB Flushing Valve Relocation

5.2.1 Relocation of Flushing Valves and Header

Relocating the flushing valves and header to a point over the CSO Basin floor would accomplish the objective of providing easier access to the valves using scaffolding for maintenance purposes.

The downside to this alternative is the need to demolish and install new pipe headers to relocate the flushing valves as well as relocate the valve actuators on the roof of the basin.

5.2.2 Relocation of Flushing Valves and Header, and Flushing Header Extension to Basin Sumps

As this alternative is just an expansion of the previous alternative, it has the same advantages and disadvantages. This alternative, however, would also have the added benefit of providing more water to the sumps to wash clear solids out of the basin during the basin flushing process.

This alternative also presents the concern of adding additional equipment in the basin sumps. This has the negative effect of adding more surfaces for solids and grit to accumulate on, as well as potential equipment failure due to clogging of flushing water nozzles.

5.3 Oakwood CSO RTB Sump Flushing/Mixing

5.3.1 Submersible Solids Handling Pumps with Nozzles System

The submersible solids handling pump with nozzles has an advantage of being a known commodity for applications similar to the CSO basin sumps where the resuspension of solids in water is needed. A pump alternative would also allow the flexibility of the Design Team to select a pump sized to provide adequate pressure and disturbance in the sump. A submersible solids handling pump could also be rail mounted to provide easy removal for maintenance purposes.

The submersible pump has the disadvantage of requiring a significant amount of equipment in the sump on which solids can collect. This alternative introduces mechanical equipment into the sump which may lead to increased maintenance activities to sustain performance of the pump and nozzle system. The nozzles added for recirculation of the wastewater are also at risk of clogging due to the buildup of solids in the basin and sump during the flushing process.

5.3.2 Conditioning Sump Pumps with Direct Nozzle

The conditioning sump pump alternative also has the advantage of being a known commodity for this type of application, being specifically manufactured to break up and suspend solids. This would also afford the Design Team the flexibility to select a pump sized to provide adequate pressure and

disturbance in the sump. This alternative would not require a header and nozzle system and would be less intrusive in the sump compared to the submersible solids handling pump alternative.

Still, this alternative would contain mechanical equipment in the sump on which solids can collect and which may need increased maintenance activities in the basin to sustain pump performance. The conditioning sump pump would likely also require the greatest electrical load of all the presented alternatives.

5.3.3 Air Induction Units to Generate Particle Suspension

The air induction unit has the advantage of being both the cheapest alternative and the alternative requiring the lowest electrical load. This alternative is also the least intrusive in the sump and contains no mechanical equipment in the sump itself.

The air induction unit has the disadvantage of its effectiveness not being proven for this type of application as it mostly used to break up FOG in wet wells. This alternative also requires space for a blower, likely on the roof of the CSO basin. The blower for the system produces sound levels at 68 to 76 decibels. Prolonged noise at this level could result in noise complaints from residents in the Oakwood neighborhood if a means to control the sound is not implemented.

5.3.4 Gravity Line Clean Out

The addition of the gravity line clean outs is expected to improve upon the present maintenance activities required to wash out the gravity drain lines. This method of cleaning out the gravity lines is intended to be more efficient and effective than the present method of entering the CSO Basin and jetting the drain lines from the sump.

As previously mentioned, the access to the cleanouts will be below the basin hydraulic grade line during wet weather events. This raises concern of effluent spilling out of the clean outs should they open before the basin is dewatered. To mitigate this concern, the clean out connections will need to be flanged for secure isolation from the hydraulic pressure within the basin.

5.3.5 Flushing Header Extension to Basin Sumps

The inclusion of this alternative would increase the efficacy of the alternatives presented in Sections 5.3.1 through 5.3.3 if used in tandem. The addition of flushing water in the sumps themselves would assist in the previous alternatives abilities to keep grit in suspension. The additional water volume would also help in diluting the amount of sludge and debris flushed from the basin channels.

This alternative does have the drawback of implementing even more equipment in the sump for debris to catch on. This addition could also lead to an increase in the frequency or duration of maintenance needed in the sumps. Still, the benefits of this alternative are expected to outweigh the detriments.

5.4 Oakwood Storm Wet Well Flushing System

Not used.

6.0 Life Cycle Cost Analysis (for alternatives analysis - applies to most equipment systems)

The Life Cycle Cost Analysis (LCCA) was prepared for the new Oakwood CSO RTB sump flushing equipment alternatives. The analysis is for a 20-year period starting from the estimated end of project construction.

6.1 Approach

The LCCA provides comparative cost estimates intended to represent order-of-magnitude estimates for equipment capital, and operation and maintenance (O&M) costs. It is intended for planning purposes and comparing alternatives and does not serve as an opinion of probable construction cost (OPCC). The costs developed for this project phase are based on general requirements of each alternative. The alternatives that were not eliminated from further consideration based on technical feasibility to meet project goals and where there are at least two remaining viable alternatives, are included in the LCCA.

For the sump flushing equipment alternatives, this includes a comparison between the:

- Submersible Solids Handling Pumps with Nozzles System (Alternative 1)
- Conditioning Sump Pumps with Direct Nozzle (Alternative 2)
- Air Induction Units to Generate Particle Suspension (Alternative 3)

Escalation rates are applied to move present costs into the future to the time when the purchase, energy use, or maintenance will occur. Then a discount rate is applied to move those future costs back to the present and provide the net present value (NPV) of each alternative. The individual escalation rates are discussed in the following sections. The discount rate applied is 4%.

6.2 Initial Purchase and Installation

Initial purchase costs are based on budgetary costs estimates for the sump flushing equipment. The costs include the sump flushing equipment, structural and hatch modifications, piping and nozzles, and electrical panels.

Supporting component purchase costs were estimated as approximate percentage of primary equipment cost. For the sump flushing equipment these estimates included 15% for miscellaneous electrical and 5% for instrumentation and control.

Installation and labor were estimated as 30% of the equipment purchased. Commissioning costs were omitted from this analysis as they would be similar for each alternative.

Contractor costs, including general conditions, permits, insurance, bonds, overhead and profit, and 30% contingency were added to the purchase, installation, and commissioning costs as an overall percentage of 75%.

The total installation and commissioning costs were escalated from February 2023 to the approximate mid-point of construction, estimated to be May 2027, based on the project schedule at the time of the analysis. The escalation rate utilized is 6% annually.

6.3 Operation, Energy, and Maintenance

Operation and energy costs for all three alternatives were based on the duration of operation of the sump flushing equipment on a yearly basis. The operation duration of the sump flushing equipment alternatives for each year was calculated based on an estimation of the number of events in which the RTB fills over the course of a year. A detailed analysis of this estimation can be found in Section 3.1 of TM-4 Oakwood Screw Conveyor & Grinder System Modifications (OKW-SCR-2). This analysis estimates about 36 events per year. The Design Team assumed an average 30-hour runtime for the sump flushing equipment per event (6 hours for the storm event and 24 hours to dewater the basin). This totals to a sump flushing equipment runtime of 1080 hours for all three alternatives over the course of a year. The nominal horsepower (HP) of each alternative converted to kilowatts (kW) and the yearly runtime were used to calculate the energy usage costs for each alternative. The two submersible solids handling pumps are rated at 5 HP each. The two conditioning pumps are rated at 15 HP each. The four air induction units are rated at 3 HP each.

The cost of electricity was assumed to be \$0.1316 per kWh at the Oakwood CSO RTB, based on GLWA power bills. An annual escalation rate of 2.7% was applied to the energy cost rate.

Maintenance costs for all three alternatives were based on an estimation of the regularity and duration of service needed for the sump flushing equipment. For all alternatives, manual cleaning of the equipment in the sump was assumed to occur quarterly and removal of the equipment from the sump was assumed to occur yearly. For the submersible solids handling pumps with nozzles system alternative, manual cleaning in both sumps was assumed to take 4 hours and equipment removal from both sumps was assumed to take 8 hours. For the conditioning sump pumps with direct nozzles and air induction unit alternatives, manual cleaning in both sumps was assumed to take 4 hours and equipment removal from both sumps was assumed to take 16 hours.

An average labor rate of \$140/hour (including benefits) was utilized. Maintenance costs were escalated 3.5% from present (2023) to the year when performed.

6.4 Decommissioning/Salvage

The salvage value was estimated as 10% of the original equipment purchase cost (before sales tax), and then escalated to the end of the 20-year analysis period using a 3.5% annual escalation rate (consistent with the maintenance escalation rate). Salvage value is shown as a negative value in the LCCA because it is an income as compared to the other values included in the analysis, which are costs.

6.5 LCCA Results

Table 6-1 provides a summary of the LCCA for the Oakwood CSO RTB sump flushing alternatives. All values in the table are rounded to the nearest \$5,000.

This analysis shows a similar 20-year NPV for Alternatives 1 and 2. Alternative 3 has a comparatively lower 20-year NPV given the lower equipment cost and electrical cost with smaller HP motor.

Table 6-1 LCCA Summary for Oakwood CSO RTB Flushing Alternatives

Alternative	Capital Costs (Year 2027)			20-Year NPV of Capital Costs	O&M Cost Breakdown (20-Year Present Values)		20-Year NPV of O&M Costs	Salvage Value (NPV)	20-Year NPV
	Initial Capital Cost	Installation, Commissioning & Startup	Total Construction Cost		Electricity	Maintenance			
Alternative 1 Submersible Sump Pump	\$165,000	\$215,000	\$380,000	\$330,000	\$20,000	\$60,000	\$80,000	\$5,000	\$405,000
Alternative 2 Conditioning Pump	\$140,000	\$185,000	\$325,000	\$280,000	\$55,000	\$85,000	\$135,000	\$5,000	\$410,000
Alternative 3 Air Induction Unit	\$105,000	\$145,000	\$250,000	\$215,000	\$20,000	\$85,000	\$105,000	\$5,000	\$315,000

7.0 Summary, Recommendations and Key Decisions

7.1 Leib SDF Flushing System

The recommended alternative for the Leib SDF flushing system is to provide a flushing header and nozzle system that provides flushing coverage for the screening inlet channels and the screening collection channel. This recommendation calls for a slight extension of the originally proposed header system into the screening collection channel. The flushing system would add flushing water to the upstream end of the screening collection channel to assist in passing solids down into the Toward Treatment Sewer system.

It is believed that this adaptation of the alternatives will provide needed help to the washdown process for both the screening inlet channels and the screening collection channel without expanding the system for outside of the original scope of design.

7.2 Oakwood CSO RTB Flushing Valve Relocation

The Design Team's recommended alternative for the Oakwood CSO RTB flushing valve relocation is the alternative which relocates the flushing valves over the CSO basin floor and extends the flushing line towards the sumps for use in assisting the resuspension of grit in the sump.

Relocating the existing flushing valves over the floor of the CSO basin will solve the present issue of maintenance crews having difficulty accessing the flushing valves. The extension of the flushing line to the sumps of both CSO basins will aid in the effort to improve the removal of solids in the basin when flushed into the sump.

7.3 Oakwood CSO RTB Flushing/Mixing System

The recommended alternative for the Oakwood CSO RTB flushing system is the conditioning sump pump with direct nozzle. This alternative is recommended as it is a known solution for this kind of application, and the Design Team believes it will deliver the best performance of all the alternatives. With the addition of the flushing water supply and spray down the alternative becomes even more effective. The conditioning sump pump with a direct nozzle will provide improvements to the sump in three ways.

- The pump suction will lift settled solids from the floor of the sump.
- The conditioning pump will chop and break up clumped solids.
- The direct nozzle will maintain water circulation in the sump to keep solids in suspension.

The combination of the conditioning sump pump with direct nozzle and the flushing water supply and spray down is conceptualized in **Figure 7-1**.

Figure 7-1
Plan View and Section View of the Combined Conditioning Sump Pump and Flushing Water Supply in the Basin Sump

The recommendation of adding accessible cleanouts outside of the basin will allow staff to access the most likely areas of plugs without having to enter the basin.

7.4 Oakwood Storm Wet Well Flushing System

The evaluation of the storm wet well flushing system demonstrated that improvements are required to maximize system effectiveness while utilizing a reasonable quantity of secondary water (not negatively impact other demands on the system).

Improvements developed based upon the physical model study qualitative evaluation.

Recommended improvements include the following:

- Operate in accordance with conceptual operating procedure above after each wet weather event
- Avoid back-up of sanitary wastewater above top of sanitary flow trench (between wet weather events due to high losses across the sanitary screen or other factors). At time of this writing, the lowest section of one screen had been removed and GLWA was considering making the same modification to the other screen when conditions allow.
- Lower existing downstream header (located beside storm pumps) and direct discharge on top of the “short” sidewall fillet at elevation high enough to establish spray pattern and minimize gap between adjoining nozzle discharges.
- In vicinity of storm pumps, add header on sanitary flow trench side of wet well. Mount above sidewall fillet, spray pattern to contact the toe of the splitter below each pump bell. Provide new isolation valve near other isolation valves on intermediate level dedicated to new header to facilitate automated or manual control from Ovation workstation.
- Lower existing upstream header to elevation set to achieve intended spray pattern above top of expansion zone sloped concrete floor slab at upstream end of system where nozzles will be closest to floor slab.
- Replace all nozzles with units providing 40–65-degree spray angle with a flat (even) spray pattern.
- Maintain approximately the same number of nozzles in each zone of the flushing system to provide similar demand on the secondary water system as compared to existing wet well zones, unless selected per nozzle flow rate allows greater number.
- Remove all sanitary flow trench covers in storm wet well to maximize trench length over which debris can be conveyed into trench and avoid debris accumulation on covers.

7.5 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

7.5.1 Leib SDF Flushing System

- GLWA confirmed the inclusion of the flushing system for the screening inlet channels and the screening collection channel.

7.5.2 Oakwood CSO RTB Flushing Valve Relocation

- GLWA confirmed relocation of flushing valves. Also confirmed extension of flushing water header to the RTB sumps.

7.5.3 Oakwood CSO RTB Flushing/Mixing System

- GLWA confirmed the implementation of the sump conditioning pump and flushing water manifold in the RTB sumps.

7.5.4 Oakwood Storm Wet Well Flushing System

- Do not add header on "back side" of splitters (sanitary trench side of the wet well).
- Lower the storm wet well flushing water header.
- Remove sanitary flow trench covers.
- Automation of flushing sequence approved and can storm wet well can be flushed after each event using the improved system/sequence.
- Do not need to maintain same water usage. Water use can be at the level needed to provide the flushing as evaluated by the Design Team.

8.0 Next Steps

The items which require advancement/further development as the design process advances includes the following.

8.1 Leib SDF Flushing System

- Select nozzle with appropriate flow and pressure characteristics for the selected area to be washed down.
- Configuration of the header location and nozzle sizing for the screening inlet channel selected for a future screen alternative will need to be developed and modified as the design progresses.
- Develop a safe method to access the proposed concrete ramp within the screening inlet channels.
- Field confirm the condition of the existing flushing water line to determine if suitable for continued use and modifications.

8.2 Oakwood CSO RTB Flushing Valve Relocation

- Development of an operational sequence for the additional flushing water added to the CSO Basin sumps. Ensure that the flushing sequence is compatible with the drain capacity and conditioning pump operations.

8.3 Oakwood CSO RTB Flushing/Mixing System

- For the recommended conditioning pump alternative, final pump size and flow rate is to be determined to provide sufficient agitation in sumps.
- Obtain life cycle cost information for sump agitation alternatives.
- Discuss with GLWA staff about prior experience with spray nozzles at other facilities, and obtain their input for the flushing water manifold at the RTB sumps.

8.4 Oakwood Storm Wet Well Flushing System

- Select nozzle with greater headloss to aid in managing quantity of water utilized for each flush cycle equipped to provide 40-65-degree spray angle, flat (even) spray pattern from the physical model study findings. This will balance water usage for this intermittent activity with projected flushing system effectiveness. Spray angle to be evaluated relative to achieving balance between energy applied to debris and reach of spray along the floor with secondary water supply limitation.
- Utilize hydraulic model to confirm water usage of improved system does not exceed usage of existing system to minimize impact to other demands on the secondary water system.
- Develop wet well flushing system design concept patterned after the optimal configuration as determined by the physical model study.
- Develop estimated duration of each flushing cycle step for inclusion in the flushing procedure as further detailed in the next phase.
- Determine how to accommodate a third header in wet well equipped with motorized isolation valve located on intermediate level.
- Consider if check valve suitable for dirty water applications should be located between header and each nozzle to minimize contents within the wet well entering the flushing water header.

2.6 Disinfection, TM-17, TM-18, TM-19, and TM-20

Oakwood RTB and Leib SDF

- Sample pumps
- TRC analyzers
- Replacement of Sodium Hypochlorite FRP storage tanks
- Replace all metering pumps with recirculation pumps, common discharge header and motorized flow control valves
- Replace chemical feed/transfer piping
- Temporary chemical feed system during construction
- Chemical mixer enclosures replacement

Technical Memorandum

Date: June 1, 2023

*Subject: TM-17 Influent WQ Sampling Program
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The water quality sampling program includes reconnaissance of the Combined Sewer Overflow (CSO) system at the Oakwood CSO Retention Treatment Basin (RTB) and Pump Station, and at the Leib CSO Screening and Disinfection Facility (SDF), selection of the sampling locations, flow monitoring, wet weather sampling (two events per location), and samples handling and shipping for testing. Data collected during the field sampling program were used to define the Chlorine Dose-Response Strategy to improve the disinfection system in both facilities.

Chlorine demand, chlorine decay, and bacteria inactivation kinetics directly correlate to water quality. Understanding the influent water quality and how it changes over time is key to determining the integrated contact time (ICT) value that will be necessary to achieve bacteria permit limits.

CDM Smith successfully collected samples at Oakwood and Leib at different channel levels and flowrates during the wet weather events to collect representative samples.

1.0 Introduction and Purpose

Our approach to define the Chlorine Dose-Response Strategy begins with the collection of undisinfected influent samples during overflow events and performing chlorine dose response testing at CDM Smith's Research and Testing Laboratory in Bellevue, Washington (BLV RTL). The purpose of the water quality sampling plan is to define requirements for collection and containment of Influent CSO samples.

2.0 CSO Facilities Background

The Great Lakes Water Authority (GLWA) operates and maintains eight CSO facilities consisting of RTBs and SDFs. All the CSO facilities have screening capabilities upstream of their respective

retention or treatment basins consisting of either bar screens or perforated-plate screens. Disinfection at each CSO facility is primarily accomplished by adding sodium hypochlorite (NaOCl) to the CSO flow, typically near the headworks. Flow enters these facilities by gravity, except for the Oakwood CSO facility which receives flow through a series of eight storm flow pumps.

2.1 Oakwood Facility (12220 Pleasant St, Detroit, MI 48217)

The facility receives flow through the combined sewer collection system piping and conduits that convey combined wastewater into Junction Chamber No. 1, which is just upstream from the pumping station. Once all flows are combined at Junction Chamber No.1, they are conveyed into the pump station through a pair of 18-ft. diameter influent conduits. The combined wastewater, consisting of both sanitary and storm flows, are managed by the pump station. **Figure 2-1** provides an overall sewer schematic for the Oakwood RTB.

When the flows into the facility exceed the capacity of these pumps during storm events, the pump station storm pumps convey any excess flow to the Screenings Facility and then into two 4.5-million-gallon (MG) CSO Basins. When the facility's 9-million-gallon total storage capacity is exceeded, any additional flow is directed through two parallel outfall conduits into the O'Brien Drain and then into the Rouge River.

2.1.1 Oakwood Sampling Procedure Summary

The following is a summary of the sample collection procedures followed for samples tested on October 31, 2022 and November 27, 2022. Sample collection preparations were made, and all sampling equipment and items were stored at the Oakwood facility near the sampling location. The Field Team Coordinator called the Oakwood facility operators to check the status of the facility equipment and the wet weather event predictions.

When significant rainfall is predicted to take place in the next 24-hour period, the field sampling team is placed on alert. After the Field Team Coordinator received the GLWA text message "PE started" alert, a 5-minute call was held between the sampling team and the Oakwood operator to review the upcoming steps and make the sure that everything was ready. As the level at the Oakwood facility started to increase, the Oakwood operator opened the hatch cover at the influent pump station entrance. The field sampling team then installed the sampling tripod assist and other necessary equipment for sampling. All safety procedures were taken (Please see the Field Sampling Plan for more details).

Ice bags, jerricans and coolers were prepared before each sampling event. Grab samples were taken at the Oakwood facility using 5-gallon buckets with the tripod assist at different times depending on the channel level and the flowrates to make sure the field sampling team had a representative sample of the first flush, during, and at the end of the overflow event. The Sampling Team Coordinator made sure that the team was following the Field Sampling Plan. Upon collection, samples were labeled in accordance with the Field Sampling Plan, logged on chain of custody (COC) forms, and immediately transferred to coolers filled with ice and maintained at $4 \pm 2^{\circ}\text{C}$. The field team was able to ship three samples (5 gallons each) per event for a total of six samples to the

Design Team laboratory for testing on October 31, 2022 and November 27, 2022. During both sampling events, the Oakwood facility was not in full operation since the two events were short in time. All activities on the field were documented properly.

2.2 Leib Facility (2198 Mt Elliott St, Detroit, MI 48207)

The facility is located on the east side of Mt. Elliott between Waterloo St. and Kercheval Ave. It is designed to treat a total CSO flow of 1,550 cfs with a capacity for flows of up to 2,000 cfs to be conveyed through the facility with partial screening and disinfection with less contact time. Flows to the facility are via the 16-ft-diameter Mt. Elliott Sewer. The 16-ft-diameter Mt. Elliott Sewer is bulkheaded south of Waterloo St. thereby diverting all flows into the influent channel of the SDF.

Figure 2-2 provides an overall sewer schematic for the Leib SDF.

2.2.1 Leib Sampling procedure summary

The following is a summary of the sample collection procedures followed for samples tested on November 27, 2022 and January 19, 2023. Sample collection preparations were made, and all sampling equipment and items were stored at the Leib facility near the sampling location. The Field Team Coordinator called the Leib facility operator (or St Aubin facility Operator if the Leib operator is not available) to check the status of the facility equipment and the wet weather event predictions. In situations when the Leib facility operator is not available the call is placed to the St. Aubin facility operator.

When significant rainfall is predicted to take place in the next 24-hour period, the field sampling team is placed on alert. After the Field Team Coordinator received the GLWA text message “PE started” alert, a 5-minute call was held between the sampling team and the Leib operator to review the upcoming steps and make the sure that everything is ready. As the level at the Leib influent channel started to increase, the Leib operator opened the basement door to give the Design Team access to the influent channel. The field sampling team then installed the necessary equipment for grab sampling. All safety procedures were taken (Please see the Field Sampling Plan for more details).

Ice bags, jerricans and coolers were prepared before each sampling event. After confirming that the two chemical induction mixers in the influent channel were off, grab samples were taken at Leib facility using a 5-gallon bucket attached to a heavy-duty rope at different times depending on the channel level and the flowrates to make sure the field team had a representative sample of the coming influent during the overflow event. The Sampling Team Coordinator made sure that the team was following the Field Sampling Plan. Upon collection, samples were labeled in accordance with the Field Sampling Plan, logged on chain of custody (COC) forms, and immediately transferred to coolers filled with ice and maintained at $4 \pm 2^{\circ}\text{C}$. The field team was able to ship three samples (5 gallons each) per event for a total of six samples to the CDM Smith laboratory for testing on November 27, 2022, and January 19, 2023. During both sampling events, the Leib facility was not in full operation (screening operation was not active) since the level in the influent channel was not enough to turn on the screens at Leib. All activities on the field were documented properly.

7.0 Summary and Recommendations

Samples for each facility per overflow event were collected as planned by the disinfection team to support the chlorine dose response testing strategy in the aim to define the chlorine demand, chlorine decay, and bacteria inactivation kinetics and their correlation to Oakwood and Leib water quality. The testing results will help the Design Team to determine the ICT value that will be necessary to ***optimize the chlorination process, reduce capital improvement costs, and reduce operations life cycle cost as identified by project guiding principles***. This goal will be achieved while simultaneously meeting/exceeding permit bacteria limits and to improve the disinfection system at both facilities. This information is being used to help design/optimize the disinfection system from conceptual design through final design.

8.0 Next Steps

The Design Team understands the influent water quality and flow rates associated with each facility needed to prepare and initial ICT model and will continue to work with GLWA to obtain more CSO data (dosage, storage volumes, Flowrates, TRC, Fecal coliform, TSS etc.) to further refine the model. Updates to the chlorine dose response testing can continue to be performed to capture different water quality conditions during the project allowing the model to be refined as the disinfection system design progresses.

Field Sampling Plan (FSP)

CSO Facilities Improvements

Field Sampling Plan (FSP)

PREPARED FOR: Great Lakes Water Authority

COPY TO: David Mccord; CSO Manager, david.mccord@glwater.org

PREPARED BY: CDM Smith Michigan, Inc.

DATE: October 18, 2022

PROJECT NAME: CSO Facilities Improvements_ Sampling phase for Disinfection Study

APPROVED BY:

1. Summary

The purpose of this technical sampling plan is to define requirements for collection and containment of Influent CSO samples. The field sampling program includes reconnaissance of the CSO system, selection of the sampling locations, flow monitoring, wet weather sampling (at least 2 events this year), and samples handling and shipping for testing. Data collected during the field sampling program will be used to define the Chlorine dose- Response Strategy to improve the disinfection system in Oakwood/Leib facilities. Understanding the influent quality and how it changes over time is key to determining the ICT value that will be necessary to achieve bacteria permit limits.

All field activities will be performed in accordance with the Health and Safety Plan (HASP) developed for this program.

2. General Responsibilities

Ali Khraizat, PE – Project Manager

Brian Hilts, PE – Disinfection Task Lead

Mohamad Baydoun, PhD – Field Team Coordinator

Julie Aichler, PE – Health and Safety Coordinator

Oakwood Sampling Team 1- Mohamad Baydoun

Leib Sampling Team 2- Nigel Beaton/ Ruby Barron

3. Sites Background

The Great Lakes Water Authority (GLWA) operates and maintains eight Combined Sewer Overflow (CSO) facilities consisting of Retention Treatment Basins (RTB) and Screening and Disinfection Facilities (SDF). All the CSO Facilities have screening capabilities upstream of their respective retention or treatment basins consisting of either bar screens or perforated-plate screens. Disinfection at each CSO Facility is primarily accomplished by adding sodium hypochlorite (NaOCl) to the CSO flow, typically near the headworks. Flow enters these facilities by gravity, except for the Oakwood CSO facility which receives flow through a series of eight storm flow pumps.

Oakwood Facility (12220 Pleasant St, Detroit, MI 48217) (Figure 1)

The facility receives flow through the combined sewer collection system piping and conduits that convey combined wastewater into Junction Chamber No. 1, which is just upstream from the Pumping Station. Once all flows are combined at Junction Chamber No.1, they are conveyed into the pump station through a pair of 18' diameter influent conduits. The combined wastewater, consisting of both sanitary and storm flows, are managed by the Pump Station.

When the flows into the facility exceed the capacity of these pumps during storm events, the pump station storm pumps convey any excess flow to the Screenings Facility and then into two 4.5-million-gallon (MG) CSO Basins. When the facility's 9-million-gallon total storage capacity is exceeded, any additional flow is directed through two parallel outfall conduits into the O'Brien Drain and then into the Rouge River. Figure 2 provides an overall sewer schematic for the Oakwood facility.

Leib Facility (2198 Mt Elliott St, Detroit, MI 48207) (Figure 1)

The facility is located on the east side of Mt. Elliott between Waterloo and Kercheval. It is designed to treat a total CSO flow of 1,550 cfs with a capacity for flows of up to 2,000 cfs to be conveyed through the facility with partial screening and disinfection with less contact time. Flows to the facility are via the 16-ft diameter Mt. Elliott Sewer. The 16-ft diameter Mt. Elliott Sewer is bulkheaded south of Waterloo thereby diverting all flows into the influent channel of the Screening and Disinfection Facility. Figure 5 provides an overall sewer schematic for the Leib Screening and Disinfection Facility.

4. Sampling Plan

4.1 Sampling Team

Sampling team will be assigned to pre-determined sampling sites during wet weather event sampling. The team is responsible for taking samples from two sites Oakwood and Leib.

During wet-weather sampling, the sampling team are responsible for assisting with pre-event planning, grab sample collection on First flush, during and before the end of the event. In addition, the sampling team is responsible for collection of flowmeter field measurements, accurate completion of data sheets and chain-of-custody forms, and delivery of samples to the Laboratory staff for testing and data to the Disinfection Task Lead.

All field personnel will undergo training prior to field sampling. A record of this training will be documented in the field notebook. One individual (with possibility of an assist from another

individual) is responsible for sampling and assigned the task of delivering samples to the appropriate laboratory.

During sampling events, the Field Team Coordinator, will serve as Event Coordinator who will be responsible for planning, oversight, and coordination of all field sampling teams, including mobilization of teams and equipment and preparation of sample Jerricans.

The Event Coordinator will also be the primary point of contact for sampling teams during the event and will coordinate between the CDM Smith and GLWA teams.

The sampling team will be equipped with a cellular communication device, maps showing the location of each station, driving directions, a list of all sampling location, the cell phone numbers of all Sampling team, GLWA operators, the Field Team Coordinator, and the Health and Safety Plan (See Appendix D for the HASP).

All necessary equipment is provided to the teams prior to each schedule event. Equipment includes safety equipment, personal protective equipment (PPE), sampling equipment, decontamination materials, rain gear, and trash bags.

4.2 Sampling Locations

Oakwood Sampling Location (Figure 2,3 and 4)

During wet weather storm conditions, combined wastewater enters the Oakwood Facility pump station through Junction Chamber No. 1, is distributed to the two well wells through the influent conduits and enters the expansion zone of the East and/or West Storm Wet wells.

There are eight duty Chemical Feed Pumps (Nos. 1 to 8) and two standby Chemical Feed Pumps (Nos. 9 and 10). Each of the duty pumps is paired to a corresponding storm pump. The chemical feed pump meters chemical to match the discharge flow and needed application rate for each pump.

LEIB Sampling Location (Figure 5,6 and 7)

During wet weather storm conditions, increased flows enter the Screening and Disinfection Facility via the Dry Weather/Influent Channel. However, since the outlet for this channel is only 3 ft in diameter the sewage flow will begin to back up in the influent channel as the flows into the facility continue to increase the longer the wet weather event lasts.

As the flow backs up, the sewage level in the influent channel rises. At 13-ft the 3-ft diameter Dry Weather Channel Isolation Gate closes forcing all the incoming sewage flow to remain in the facility's Screen Chamber. Flows will continue to rise in the influent channel as well as the four screening inlet channels and begin to pass through the COPA horizontal screens and the ROMAG vertical screens.

Disinfection chemical application at the Leib CSO facility is currently achieved with chemical induction mixers. There are two pre-chlorination mixers in the influent channel upstream of the screening channels and 16 chlorination mixers downstream of the screening channels where there are four rapid mix zones with four chlorination mixers in each zone.

4.3 Event Response Plan Summary

- Daily, the Field Team Coordinator will review predicted rainfall amounts and patterns for 5-7 days in advance.
- If significant rainfall is predicted to take place in the next 24-hour period, the field sampling team will be placed on alert.
- Sample collection preparations will be made. The Field Team coordinator will call the GLWA CSO Operators to check the status of the facility equipment and the wet weather event predictions.
- The Field Team Coordinator will keep monitoring the weather and the GLWA SCADA system with GLWA Operations staff to help make the decision.
- As the Field team coordinator receives the GLWA SMS “**pre-storm**” alert. A 5 min call between the sampling team and GLWA operator to review sampling plan and make the sure that everything is ready and alerted.
- GLWA staff phone numbers:
 - Georgianna Lindsey – Leib –, 313-400-6239
 - Kelvin Jackson and/or Ira Hawkings – Oakwood –313-999-0537 / 313-400-6900 respectively.
 - David Mccord- CSO Manager- 313.822.2017
- CDM sampling team phone numbers:
 - Mohamad Baydoun 313-230-5606
 - Ali Khraizat 313-230-5614
 - Ruby Barron 773-603-1144
 - Nigel Beaton 269-903-1218
- Field team coordinator monitors the SCADA system to determine the perfect time to go take samples
- Sampling team 1 and 2 will arrange time to pick up Ice bags for coolers on their way to the sampling locations.
- Once the team receives the “**wet weather**” alert, Field team coordinator along with sampling team will mobilize quickly to capture the event. Sampling team needs around 30 min to arrive at both facilities.

- Samples (3 five gallons jerricans) will be captured on first flush, during and before the end of the wet weather event.
- Samples will be collected and handled properly and then shipped after checking shipping company schedule (FedEx, UPS etc.) to the laboratory for testing with the chain of Custody sheet.
- The Field team coordinator will make an event stop call once discharges have ceased.

4.4 Field Mobilization

Once a wet-weather sampling event has been identified, the Event Coordinator and Sampling Teams are responsible for ensuring that all sampling-preparation activities are completed.

These activities include:

- Procurement of field equipment and calibrated sampling equipment
- Procurement of ice bags (35-40 pounds), sample Jerricans (3 per location), coolers (3 per location), and temperature blanks (3 per location).
- Ensuring that all sampling personnel have reviewed the Field Sampling Plan and the Health and Safety Plan, and have received instruction on sampling and measurement techniques, documentation, and sample custody procedures for the project.
- Confirmation of GLWA site access.
- Arrangement of transportation and availability of at least one personnel on-site and another on-call at the time of wet weather event.
- Coordination with all the teams involved between CDM Smith and GLWA on the sampling day.

4.5 Sampling Event Start Timing

The timing of wet-weather events is more uncertain than that of dry-weather events. The process requires adaptive planning both before and during events.

Each sampling location will have its own time of concentration to consider. Flow observations collected through GLWA SCADA system at each site, and the alert phone message system will be used to estimate appropriate timing of grabs for each location.

4.6 False Starts and Aborted Events

Given the uncertain nature of precipitation, there is potential for false starts and aborted sampling events because of changes in precipitation patterns, volumes and/or durations, particularly for wet-weather surveys.

In all cases, CDM will determine whether an event will be aborted following mobilization of sampling teams to the field. Under some circumstances, the event may not be fully aborted, but postponed based on predicted event timing. The Field Team Coordinator will notify sampling

teams and GLWA Operators in the event of termination or postponement due to weather conditions.

4.7 Flow Monitoring

Flow meters are working properly at both facilities. The Field team Coordinator will check the flow meters, and he will monitor the flow during the wet weather event. He will make sure to take the flow numbers at the same time of sampling.

4.8 Influent analysis parameters

A wide range of parameters were selected to effectively characterize water quality. Table 1 lists the Influent parameters selected for each sampling event at each location (see appendix E).

During a wet weather event all samples will be collected by grab. Grab sampling is the most appropriate for our testing to make sure we are targeting the rising-limb of the storm hydrograph.

4.9 Decontamination Procedures

All materials used during the collection of samples and any non-dedicated sampling equipment that may contact the sample, will be decontaminated (washed with 70% Isopropyl and rinsed with distilled water) before sample collections and after each use. The equipment will be rinsed with distilled water and allowed to air dry.

4.10 Grab Sample Collection Method

Grab samples will be taken at Oakwood facility using 5 gallons bucket with a tripod assist and at Leib facility using a 3-Gallons bucket attached to a Chain. Samples are 5 gallons volume for each sampling time, with 3 sampling times planned per event and per location, approximately one hour apart.

The jerrican used for sample collection will be triple rinsed with sample water and then returned to the site. That is, a small amount of sample (approximately 500 mL) will be dispensed into a given jerrican, thoroughly shaken and then dumped out; this is repeated three times before collecting the actual sample.

The sampler will have to completely filling the jerricans such that there is no remaining headspace. Multiple grab samples will be composited into a single jerrican for each sample point in the wet weather event.

The sample collection device will be disinfected with 70% isopropanol between sample points to prevent cross contamination. To prevent photooxidation and limit additional microbial growth, samples will be kept on ice in a cooler while sampling and not exposed to sunlight unnecessarily or for extended periods of time.

Samples stored in cooler with ice to be ready for shipping. temperature blank bottle will be filled with tap water and stored in the sample cooler. All field observations, including flow conditions, are recorded on a Sampling Worksheet filled out for each site.

4.11 Sample Jerricans handling

All samples sent for laboratory analysis will be collected directly into the 5 gallons Jerricans for testing. Upon collection, samples will be labeled in accordance with Section 5.12, logged on chain of custody (COC) forms, and immediately transferred to coolers filled with ice and maintained at $4 \pm 2^{\circ}\text{C}$.

Samples will not be allowed to freeze in transit. Jerricans with chips, cracks, or etched surfaces will be discarded and replaced. If damaged Jerricans cannot be replaced, samplers will collect the sample in the damaged Jerricans and make note on the label and chain of custody. Jerricans closures will be watertight. Sample Jerricans will be secured and not be totally immersed in water during transit or storage.

The COC form filled out for the jerrican in each cooler will be completed by the sampler, placed in a Ziploc™ bag, and taped to the inside lid of the sample cooler. For the first sample shipment only, a sample shipment memo (SSM) (Appendix B) is required. The SSM will be completed by the Field Coordinator and submitted by email to the CDM Smith RTL Chemical Hygiene Officer (CHO) Mary Lou Fox (FoxML@cdmsmith.com) and the CDM Smith RTL Technical Lead, Dung Nguyen (nguyendd@cdmsmith.com) prior to sample collection.

4.12 Sample Identification and Custody

Sample labelling

The jerrican will be numbered in the order of sample collection with the following naming convention: LOCATION-YYYYMMDD- SAMPLE POINT. For example, OAKWOOD-20221001-INITIAL. This jerrican identifier will also be what is entered on the COC. One jerrican will be placed in each cooler.

Sample labels will be pre-printed in adhesive paper and covered with clear tape after they are affixed to the sample Jerricans to prevent damage to the label during transport to the laboratory.

After collection of water, a permanent ink will be used to mark the sample labels with the initials of the person who obtained the sample, date and time collected, and other relevant information.

Ice will be filled in double bagged sealable Ziploc™ bags to fill the remaining space of each cooler. The double bagged ice fill be filled as shown in Figure 8, where the seals are oriented opposite each other to prevent leaking. Double-bagged ice will be placed on the bottom of the cooler, in-between sample and cooler, and on the top of samples.

Figure 8 Double-bagging technique to prevent leaking.

Chain of Custody

A chain-of-custody (COC) procedure will be used to properly document each sample to ensure timely analysis of all parameters requested and to track the progress of samples in the laboratories. The chain-of-custody forms for each set of samples are filled out before Shipping samples to the laboratory. The appropriate chain-of-custody form will be placed in a waterproof plastic bag and affixed to the inside cover of the cooler that is sent to the lab.

All samples within a given package will be recorded on the chain-of-custody form. The Field Team Coordinator is responsible for filling out the chain-of-custody form including signing and dating the form. One copy of the chain-of-custody form will be retained by CDM. This copy will be maintained in a notebook of sequentially numbered chain-of custody forms.

Each time the samples are transferred, the person accepting the samples must sign and date the chain-of custody form and indicate the time the transfer occurred. The laboratory will return the completed chain-of-custody form containing all original signatures to CDM with the data report that provides the results of the requested analyses on a given package of samples. A copy will also be retained by the laboratory for their records.

4.13 Sample delivery logistics

This section outlines delivery logistics that will be implemented by the sampling teams during sampling events.

During sampling events, the CDM office in Detroit will act as the centralized coordination location. Grab samples collected at the sampling sites will be transferred to the centralized coordination point. The Field Team Coordinator will be assigned the task of shipping the samples from CDM to the appropriate laboratory.

Prior to sample collection, a conference call among the CDM Smith team members will be held to discuss sample collection, packing, and shipping techniques (See Appendix B for an example sample shipment memorandum).

Samples will be shipped the day of collection with sufficient double-bagged ice via FedEx priority overnight or equivalent service to the following attention at Research and Testing Laboratory. If samples cannot be shipped out the day of collection, samples will be stored at 4°C until they can be shipped. Any storage of samples prior to shipment will be communicated by field staff to the CDM

Smith RTL staff and will not exceed 24 hours from sample collection. Each cooler must include a temperature blank and proper chain-of-custody (COC) documentation detailing the number of jerricans, time and date of sample collection. The COC form is included in Appendix C.

When sampling is complete, the field coordinator will email Dani Tran (trandn@cdmsmith.com), cc Dung Nguyen (nguyendd@cdmsmith.com) and provide information on the conditions at the facility at the day of sampling (water flows, any unique aspects of operations, and the procedures of sample collection).

The field coordinator will also email the tracking number to Dani Tran on the day the samples are shipped out. Each cooler will contain a temperature blank (tap water in a poly container), which will be used to evaluate temperature upon receipt of the sample water. If wet weather happens Monday through Wednesday, samples will be shipped to the CDM Smith RTL and analyzed immediately. If wet weather happens after Wednesday, then samples will be collected and shipped to the CDM Smith RTL, stored at the lab, and will be analyzed depending on the CDM Smith RTL staff schedule

For the first round of testing, once the samples are shipped, the Field Team Coordinator will participate in the first chlorine dose response analysis at the CDM Smith laboratory in Bellevue WA.

Samples will be shipped to the following address:

ATTN: Dani Tran
14432 SE Eastgate Way, Suite 100
Bellevue, WA 98007
Office: (425) 519-8321

4.14 Field Documentation

Proper documentation of all field activities is essential to ensure that the data quality objectives are achieved. Sample teams should document any unusual or anomalous conditions that may later be useful for data interpretation and analysis.

During wet-weather events, data will be recorded on Sampling Worksheets. Information from the Sampling Worksheets will be converted to electronic databases after the event.

In addition to collecting grab samples, the sampling teams will note conditions near the sampling site. In particular, the sampling teams will be asked to record the flow conditions observed at the time of the grab.

5. Health and Safety Procedures

A separate Health and Safety Plan (HASP) was developed for Sampling plan and is included as Appendix D.

Appendix A

Wet Weather Event Activities

Mobilization Phase

Sampling equipment including sample Jerricans, field packets, Coolers, Sampling Buckets, and other field equipment must be collected from the CDM office in Detroit either the evening before or the morning of the anticipated wet-weather event. In between events, teams are allowed to store equipment in their vehicle, home, office, or other secure place at their convenience, as long as it is available during the events.

Planning is based on the forecasted grab-time announced in the 48-hour notification and updated as the event approaches.

Once the SMS GLWA message alert received declaring the “Pre-Storm” alert, a 5 min call will be performed between CDM Smith team and GLWA Team to coordinate the sampling plan while monitoring the SCADA system to identify timing of the wet weather event.

Activities performed at the time of the wet weather event:

- (1) Team will be at the first of two sampling locations at the forecasted grab-time wearing the prescribed PPE and have all the Grab sampling equipment and grab sample Jerricans.
- (2) Go to the sampling locations at both facilities where the grab is intended to be taken. Observe and report the flow condition sampling worksheet.
- (3) Take the 15 gallons sample (3 five gallons a different time points: first flush, during and before the end of the wet weather) by grab from each location.
- (4) Record a single time for the grab sample on each Jerricans and on the sampling worksheet.
- (5) When all grabs are finished. Make the area is safe around your sampling location. Perform a complete decontamination of the grab sampling equipment used.
- (6) Do the same sampling process for the other site (steps 1 through 6).
- (7) Immediately return to the CDM Smith office to prepare samples for shipping.

Appendix B

Sample Shipment Memorandum

To: Whom It May Concern

From: Dung Nguyen, CDM Smith Environmental Research and Testing Laboratory (Bellevue, WA)

Date: 10/01/2022

Subject: Procedure for Samples Shipping to Treatability Lab (Bellevue, WA)

This memo contains procedures for sending samples to the CDM Smith Research and Testing Laboratory located in Bellevue, Washington. It is intended to be used by anyone who sends environmental samples to the Research and Testing Laboratory, regardless of whether they are CDM Smith employees or not.

Research and Testing Laboratory staff or project managers will provide this memo to the sender prior to the sample shipment. Upon receipt, the sender must read it carefully and fill it out to the best of their knowledge before preparing the samples for shipping.

Once the memo is complete, it must be submitted to the Field Team Coordinator for review.

Upon the completion of review, a completed and approved copy of this memo must be shipped together with the sample(s) to the lab.

Before Shipping

It is the sender's responsibility to classify the samples to be shipped. If the samples are classified as Dangerous Goods, the sender must have applicable training on DOT and IATA regulations before initiating the shipment. For example, Fedex will not allow shipping of dangerous goods unless the sender has been trained on proper procedures. Furthermore, there can be significant penalties (up to \$50,000 per violation, per day) that can be imposed by DOT on the sender PERSONALLY (not just the company) if noncompliant shipments are offered by a shipper.

CDM employees should be familiar with CDM policy, located here:

http://cdmweblegacy/h&s/documents/hazmat_transport.doc

http://cdmweblegacy/h&s/hazmat_transport.html

Sample Shipment Procedures

1. Communicate with Research and Testing Laboratory Management regarding sample information and desired scope of work.

Charles Schaefer,

ETL Director

425-519-8300

schaefer@cdmsmith.com

Jennifer Hooper,
Technical Lead, Water and
Wastewater
hooperjl@cdmsmith.com

Zoom Nguyen, Technical
Lead, Remediation
nguyendd@cdmsmith.com

Mary Lou Fox,
Chemical Hygiene Officer
foxml@cdmsmith.com

2. Receive written approval from Research and Testing Laboratory Management for sample shipment (i.e. this memo, once completed and approved).

3. All the sample containers must bear a readable label with the sample name and contents, the related project name, the sender's name and company, the sample collection date, and any other appropriate sample information.

4. Prepare shipment per DOT and IATA regulations. Include a completed Chain-of-Custody form.

5. Send samples via overnight courier to the Research and Testing Laboratory:

CDM
Attn: Janelle Amador
14432 SE Eastgate Way, Suite 100, Bellevue, WA 98007

6. Inform Research and Testing Laboratory Management of shipping status and provide tracking number.

Sample Information Required Prior to Shipment

1. Source

Please check all of the following boxes that are applicable regarding the nature of the sample:

- | | | |
|--|--|---|
| ☐ Groundwater | ☐ Subsurface soil | ☐ Industrial Waste Water |
| ☐ Surface water | ☐ Surface soil | ☐ Municipal Waste Water |

2. Contaminants

Please check all of the following boxes that are applicable regarding contaminants in the sample:

- | | | |
|---|---|--------------------------------------|
| ☐ Chlorinated Solvents | ☐ Petroleum Hydrocarbons | ☐ Metals |
| ☐ Radioactive Substances | ☐ Pesticides/PCBs | ☐ Perchlorate |
| ☐ Unknown | | |

Please list specific contaminants:

3. Hazards Information

Based on the SDS or other sources of the sample hazards information, please check all of the following boxes that are applicable.

- | | | |
|------------------------------------|------------------------------------|--|
| ☐ Flammable | ☐ Toxic | ☐ Unknown, but is potentially hazardous |
| ☐ Reactive | ☐ Corrosive | ☐ None apply |

Notes:

4. Potential Headspace Gas Accumulation

- Sample will be shipped on ice? ☐ Yes ☐ No
- Any potential for gas generation/accumulation in the sample container during the transportation? ☐ Yes ☐ No
- If yes to the question above, please specify what are the gases could be encountered in the container upon receipt:

5. Sample handling information

- Does the sample require refrigeration on arrival? ☐Yes ☐No
- Will a temperature blank be included to verify appropriate temperature control during shipping? ☐Yes ☐No
- Does the sample require protection from oxygen contamination (i.e., should the containers be opened only in an anaerobic chamber)? ☐Yes ☐No

If yes:

- Water samples must be shipped in containers of 1L or smaller
- Soil cores must be no more than 16" long. Other containers should be no larger than 15" x 8" x 8".

6. Additional Sample Information

Please indicate if any of the following sources of information are included for the sample.

- ☐SDS ☐Product Sheet ☐Source Materials Information
☐No Additional Info Available

Notes: _____

Sample Sender's Name (print): _____

Sample Sender's Signature: _____

Date: _____

Approved for shipping? ☐Yes, ☐No,

☐Additional Information is needed, which includes:

Approved by: _____ (Print)

_____ (Signature)

**CDM
Smith**

CDM Smith		General Health and Safety Plan	
CDM Smith Activity Hazard Analysis			
Project Name:	CSO Improvements Project	Project No.:	276260
Analyzed by:	Julie Auchter	Date:	09/19/22
Reviewed by:	Jeffrey Rakowski	Date:	09/19/22
Description of Work Activity			
The tasks to be performed onsite are: Observe operation of CSO control facilities (OKW & Leib); Collect location and measurement information for various process equipment and potentially structures (all facilities, specifically for mixers at BC, CC, Leib); collect water samples from the treatment process (at the influent before the chemical injection); analyze water samples for TBD (potentially Free Chlorine, TRC, pH, Temp, TSS, BOD, TOC, Ammonia); transport samples to GLWA lab or for shipping to CDM Smith lab; remove and replace sample nets from flow chambers to analyze performance of screening system (Leib).			
Potential Hazards	Hazard Controls (Examples provided at this link)		
Slips, Trips, Falls	Samples & measurements (where feasible) will be collected at points engineered for the purpose. Use caution when working in the CSO facility and near the collection or the discharge point. Stay clear of any spills. Follow GLWA personnel instructions and floor markings when walking through the facilities to avoid tripping hazards.		
Falling hazards around open holes	The buddy system will be used at all times during work done near open holes. Crew members will approach open hatches with caution and determine safe places to stand and safe ways to approach and work near each hatch or opening. Plan ahead for field measurements/needs so bring necessary poles, boards, measurement tools, lights, etc. with you to perform work safely and effectively. Attempt to do the following as feasible: Stay low to the ground while performing inspections; Do not turn back from openings; Do not completely remove manhole cover from hole		
Physical hazards due to raising and lowering of hatches at the facilities and outfalls	Coordinate with GLWA staff prior to field visit to determine if they have staff person available to accompany CDM Smith staff and open/close hatches. Proper tools and lifting techniques must be used to lift the hatches, and extreme caution must be executed when closing the hatches to avoid bodily injury such as crushed toes or feet. Wear safety toe boots/shoes.		
Confined space accidents/sewer gas exposure	Comply with CDM's confined space entry requirements and procedures. Only CSE trained employees will perform work in confined spaces. Coordinate with GLWA staff prior to field visit to verify which spaces are classified as permit or non-permit confined spaces and any other site specific requirements & planning information needed.		
9/22/2022		AHA	

Potential Hazards	Hazard Controls (Examples provided at this link)
Exposure to non-hazardous calibration solutions (pH, chlorine residual analyzer)	Wear appropriate clothing at all times wear long sleeve shirt, pants, closed toed shoes, eye protection; wash hands before and after sample collection
Ingestion of chemicals or microbial agents	Wash Hands thoroughly. Avoid getting calibration solutions in mouth and chlorine reagents. Read the SDS of each chemical you are in contact with to make sure you are doing the right handling procedure.
Electrical Hazards	Care must be taken when working near electrical equipment and instruments. Only qualified personnel should work on or around this equipment. Operators shall become familiar with warnings, safety notices and maintenance procedures.
Sampling bottle & CSO screening net handling	Gloves will be worn when handling CSO samples or nets located on screen discharge. Do not touch the inside of the CSO sample bottle.
Mechanical hazards associated with the treatment process	Discuss our work with plant personnel whose operations may endanger the team, or that might be affected by our presence. Work out safe places to stand. For screenings characterization work out safe ways to access raw and processed screening material.
Lifting Injuries	Use proper lifting techniques to avoid lifting injuries
Night Time Sampling or Site Visits	Wear high visibility clothing (vest) and use proper work area lighting. Traffic safety plan if in or near traffic lanes. Perform work with another person (buddy system).
Cold Stress	Check the weather forecast prior to site visits. Account for higher winds outside facilities near the river or with elevated structures (i.e. on top of OKW basin) and dress accordingly. Take breaks inside the facility's heated spaces to warm up periodically if feel cold.
Exposure to microbial agents and debris from screenings	Wear protective eye wear and face shield in locations where samples or screenings samples are subject to splashing/splatter
Personal Security	Be aware of surroundings and security protocols arriving and leaving the site. Perform work with another person (buddy system). Choose areas with good lighting and visibility when parking vehicles.
Training Required	
Project Safety Orientation	All of the time - work clothes, cell phone
	For appropriate situations - safety toed shoes (opening/closing hatches, CSE, minimum)
	For appropriate situations - safety glasses
	Wear latex/nitril gloves when handling CSO samples

Potential Hazards	Hazard Controls (Examples provided at this link)
	Wear Leather gloves Opening/closing hatches or manholes
	Wear hard hat and safety glasses and high visibility vest in areas where required
	For problem situations - good judgment, first aid kit
Confined Space Entry Training	For CSEs - staff must be trained and have a health & safety manager approved permit prior to entry
HAZCOM Training	Employees potentially exposed to or working with chemicals are to take HAZCOM training prior to activities. Review SDS for all chemicals/reagents that will come in contact with.

Emergency Plan and Information			
Basic Approach:	If an emergency happens, the CDM Smith team will rapidly, but without haste, withdraw to a safe location and notify the appropriate emergency agencies listed below.		
Police:	Dial 911		
Fire:	Dial 911		
CDM Smith H & S Manager	Joe Sabo	857 / 500 - 3636

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

From: CDM Smith

Date: June 1, 2023

Subject: TM-18 Chlorine Dose Response Results and ICT Model

1.0 Executive Summary

The Design Team developed CSO disinfection efficacy models to determine the integrated contact time (ICT) necessary to achieve bacteria permit requirements at the Oakwood Combined Sewer Overflow (CSO) Retention and Treatment Basin (RTB) (Oakwood) and Leib Screening and Disinfection Facility (SDF) (Leib). The models were developed and calibrated using data from benchtop chlorine dose response tests from several wet weather events at both facilities in 2022 and 2023. Correlations between demand-dose responses and water quality were also explored. The data from these tests resulted in “high” ICT values of 120 and 142 mg-min/L, and “average” ICT values of 50 and 50 mg-min/L at Oakwood and Leib, respectively. The ICTs were selected based on log inactivation and final bacteria counts in accordance with each facility's permit requirement. The ICT values were utilized to size the improvements to the sodium hypochlorite storage and feed systems for both Oakwood and Leib.

2.0 Introduction

As part of the CSO Facility Improvements project the Great Lakes Water Authority (GLWA) is making disinfection system improvements to the Oakwood RTB and Leib SDF. Those improvements include upgrading the sodium hypochlorite storage, feed, and mixing systems at both facilities to improve their reliability, flexibility, simplicity, ease of operation and maintenance, and robustness, all with an eye toward doing so in a way that optimizes the amount of chemical utilized to meet the discharge permit requirements. In order to meet these project goals, the design criteria, specifically identifying the appropriate chlorine dose, for the new sodium hypochlorite systems had to be established.

The Design Team conducted a disinfection study to determine the chlorine dose required to treat CSO at Oakwood and Leib. The study centered around performing bench-scale chlorine dose response tests on undisinfected, wet weather samples collected at both Oakwood and Leib, where chlorine doses and contact times were varied and correlated with the log inactivation of fecal coliform. Water quality characteristics were measured as they varied through wet weather events and tend to correlate with chlorine demand. The study utilizes the data generated from the chlorine

dose response tests to develop a disinfection efficacy model that can determine the appropriate ICT value required to meet the bacteria limits in the discharge permit. The ICT value is then utilized in conjunction with the facility specific effective contact time and the chlorine demand and decay to calculate the chlorine dose required.

This technical memorandum (TM) summarizes the study objectives, the testing plan, the analytical procedures performed, the analysis of the data, the results of the study, and the conclusions and recommendation based on these results. TM-20 further explains how the chlorine dose is calculated using the results from this disinfection study.

3.0 Objectives

The purpose of the testing outlined in this memo was to:

- Gather data on the water quality of wet weather events at Oakwood and Leib by collecting samples for analysis.
- Generate disinfection efficacy models to determine the required ICT value to meet the design target for fecal coliform.
- Determine what correlations exist between water quality and ICT values.

4.0 Testing Plan

Three separate samples were collected for each of two wet weather events at Oakwood and Leib. One additional sample at Oakwood and two additional samples at Leib were collected on 2/27/2023 to supplement the initial testing. It is assumed that the water quality of the flows from Meldrum Sewer and Leib are comparable given that the contributing areas were developed around the same time, and both are comprised of a mix of residential, industrial, and transportation land uses. Therefore, it is assumed that the sampling conducting is representative of both the Meldrum Sewer and Leib collection area water quality characteristics. Samples were kept at or below 4°Celsius (C) and sent with overnight delivery to CDM Smith's Research and Testing Laboratory in Bellevue, Washington (BLV RTL) to perform the chlorine dose response testing. TM-17 summarizes the effort associated with the influent water quality sampling program.

An experimental matrix was developed, prior to initiating the sampling, with chlorine doses and contact times that would generate a wide range of ICT values necessary to develop robust disinfection efficacy models for the water quality represented in these samples. The experimental matrix for all samples is shown in **Table 4-1**.

Initial chlorine demand testing was performed for each sample upon arrival at the lab. These tests were used to determine the chlorine doses for each facility and event. The doses delivered at Oakwood ranged from 2 to 9 mg/L and were different for each event. The doses delivered at Leib were always 5, 8, and 12 mg/L, regardless of the event.

Table 4-1 Initial Test Matrix

Facility	Sampling Date	Disinfectant	Doses (mg/L)	Contact Times (minutes)
Oakwood	10/31/2022	Chlorine	2, 4, 6	0, 1, 3, 7, 15, 30
	11/27/2022	Chlorine	3, 5, 8	0, 1, 3, 7, 15, 30
	2/27/2023	Chlorine	4, 6, 9	0, 1, 3, 7, 15, 30
Leib	11/27/2022	Chlorine	5, 8, 12	0, 1, 3, 7, 15, 30
	1/19/2023	Chlorine	5, 8, 12	0, 1, 3, 7, 15, 30
	2/27/2023	Chlorine	5, 8, 12	0, 1, 3, 7, 15, 30

Table 4-2 lists the parameters and analysis methods performed as part of the chlorine dose response testing. Measurements of fecal coliform, total organic carbon (TOC), and time series studies (TSS), were performed by AmTest to simplify sampling and improve cost effectiveness. All other lab analysis was performed by CDM Smith at BLV RTL.

Table 4-2 Test Methods Performed by Testing Labs

Parameter	Lab	Analysis Method
Fecal Coliform	AmTest	SM9223B
TOC	AmTest	SM5410B
TSS	AmTest	SM2540D
Ammonia	BLV RTL	HACH Method TNT830
pH, Temp	BLV RTL	Probe
COD	BLV RTL	HACH Method 8000
Color (Apparent)	BLV RTL	SM5910
UV-254 (Unfiltered)	BLV RTL	SM5910
Free Chlorine	BLV RTL	HACH Method 8121
Total Residual Chlorine	BLV RTL	HACH Method 8167

5.0 Analytical Procedure

This section describes the chlorine dose response test procedures performed by the Design Team. The analytical procedures were developed by the Design Team specifically for this project to ensure that reliable results were obtained for design purposes. The full procedure is included as Appendix A.

Upon receipt of water samples by BLV RTL a chlorine demand test was performed by dosing each sample with a known volume of chlorine stock solution and measuring the residual chlorine concentration at several known intervals. The total residual chlorine analysis was completed using a Hach kit. The results from the chlorine demand test helped the team refine the chlorine doses to be utilized in the chlorine dose response tests as the water quality variability of each sample can render the dose response tests useless if a dose is too high or too low. Chlorine dose response tests were performed by dosing the samples with a known volume of chlorine stock solution and

measuring both the total residual chlorine and fecal coliform concentration at specific contact times.

Two sets of the wet weather samples presented complications in the analytical procedures to measure bacteria. Typically, samples are warmed up to room temperature prior to measuring undisinfected bacteria and performing chlorine dose response tests. However, for the 10/31/2022 event at Oakwood, the undisinfected bacteria measurements for fecal coliform were taken from a sample shipping container that had not warmed up to room temperature. The lower temperature of the undisinfected bacteria sample resulted in lower fecal coliform counts when compared to the bacteria counts at the first two contact times of the first chlorine dose response test. All subsequent chlorine dose response tests were performed correctly by allowing the sample container to warm up to room temperature prior to collecting samples. For modeling purposes, the undisinfected count was taken as the maximum fecal coliform observed, typically occurring at either the 1- or 3-minute mark of the chlorine dose response tests. One measurement of fecal coliform taken at the 15-minute interval was omitted given that it was higher than the previous four measurements taken (**Figure 5-1**). In addition to the outlier fecal coliform count, one outlier measurement of total residual chlorine (TRC) (**Figure 5-2**) taken at 30 minutes was higher than the preceding five measurements and omitted prior to disinfection modeling.

For the 11/27/2022 event at Leib, The Design Team identified several outlier measurements of fecal coliform. These outliers (**Figure 5-1**) differed by more than one order of magnitude (one log) from both the preceding and subsequent measurements. The four outliers were removed prior to disinfection modeling to avoid compromising model performance. Data from and analysis procedures for these chlorine dose response tests, including the duplicate QAQC samples, were reviewed and no issues were found. The outlier measurements from Leib are discussed further in Section 6.1. A summary of all omitted values is provided in **Table 5-1**.

Omitted Total Residual Chlorine Measurement at Oakwood (10/31).

Table 5-1: Summary of Omitted Total Residual Chlorine and Fecal Coliform Measurements.

Facility	Event	Sample	Chlorine Dose (mg/L)	Parameter	Time (min)	Omitted Value
Oakwood	10/31/2022	1	2	Total Residual Chlorine (mg/L)	30	0.76
		1	2	Fecal Coliform (CFU/100mL)	15	6,500,000
Leib	11/27/2022	1	5	Fecal Coliform (CFU/100mL)	7	120
		1	8	Fecal Coliform (CFU/100mL)	15	430,000
		1	12	Fecal Coliform (CFU/100mL)	3	11,000
		2	5	Fecal Coliform (CFU/100mL)	30	570,000

6.0 Results

The following subsections present raw CSO water quality data, describe the disinfection modeling approach, and provide disinfection modeling results.

6.1 Water Quality

When chlorine is added to wastewater in a combined sewer system, some fraction of it is instantly consumed, and is referred to as chlorine demand. The magnitude of this instantaneous demand is dependent on water quality of the water being disinfected. The concentrations of certain water quality parameters, such as organic matter (total suspended solids), nitrite and ammonia will have a significant impact on the chlorine demand. Ammonia, for example, reacts with chlorine to form chloramines. The chloramines are a weaker, yet effective, disinfectant than free chlorine, and the specific types and amounts are pH dependent. Reactions with organic matter and nitrite can increase chlorine demand, thereby reducing the residual chlorine available for disinfection.

Disinfection efficacy is directly correlated to ICT (mg-min/L), defined as the area under a chlorine dose response curve and is dependent upon the total residual chlorine concentration (C) (mg/L) and the effective contact time (T) (min). Total residual chlorine (TRC) includes free chlorine residual, which is a strong oxidant, chloramine residual, which generally are moderate oxidants, and chlorine reducing compounds, which have no disinfection value. Total chlorine residual at a given time is affected by water quality, so water quality characteristics are a key factor in disinfection efficacy. An ICT value is determined from chlorine dose response testing using **Equation 1** shown below.

Equation 1 Integrated Contact Time Formula

$$ICT = \frac{C_o - D}{k} * (1 - e^{-kt})$$

Where,

ICT = integrated CT (mg-min/L)

t = the effective contact time (theoretical contact time x baffling factor) (mins)

C_o = Chlorine dose (mg/L)

D = Chlorine demand (mg/L) (from chlorine dose response testing)

k = Chlorine decay (mg/L) (from chlorine dose response testing)

Water quality results from each sampling event for Oakwood and Leib are presented in **Table 6-1** and **Table 6-2**, respectively. Samples for each wet weather event are identified as “1”, “2”, and “3”, and reflect the order of sample collection during the wet weather event.

It is important to note the highly variable water quality characteristics in all four sampling events, and even between the first, second, and third samples within a sampling event. The variability in water quality helps establish a rough operational envelope a disinfection system will be required to perform within. Given this variability in water quality, without any predictable pattern, it will be important to utilize conservative design criteria to ensure that the disinfection system will be effective under a wide range water quality conditions (i.e. both high and low organic loading). Seasonal variations in water quality of wastewater treatment plant influent served by combined and sanitary collection systems are well documented and understood in the water industry. In the same way, seasonal variations in water quality are typically observed in combined collection system wet weather events. Therefore, collecting additional samples for both water quality analysis and chlorine dose response testing over a 12-month period provides an opportunity to characterize the water quality during those wet weather events and allow for a refinement and increase in confidence of the results from this study.

For example, as shown in **Figure 6-1**, TSS concentrations were approximately two times greater in Leib than in Oakwood during the first two sample events at each facility. 2/27/2023 TSS measurements at both Oakwood and Leib were significantly lower than measurements collected during previous events. Daily precipitation was analyzed across several rain gages in proximity to the Oakwood and Leib facilities. Daily event and previous 14-day totals are averages between gages per facility and summarized in **Table 6-3**. Previous 14-day totals at Oakwood (1.1") and Leib (0.7") were significantly larger on 2/27/2023 when compared to the other events, suggesting a "first-flush" in which pollutant build up over a dry period washes off during a wet weather event, may have occurred prior to the sampling event and contributed to lower TSS on 2/27/2023. It is worth noting that the rainfall measured for the previous 14 days period ahead of the 2/27/23 sampling event all occurred during a single storm event on 2/23/23. Low snowfall totals in the 14 days prior to sampling indicate snowmelt was not likely to be a significant factor in flushing the collection system. The higher concentrations of particulate matter (sample photos shown in **Figure 6-2**) likely contributed to lab measurement complications and the subsequent fecal coliform omissions presented in **Figure 5-1** and **Table 5-1**.

Table 6-3 Summary of Rainfall and Snowfall Totals by Facility and Event

Event	Oakwood		Leib		Previous 14-day Total Snowfall (in)
	Day of Event Total Rainfall (in)	Previous 14-day Total Rainfall (in) ¹	Day of Event Total Rainfall (in)	Previous 14-day Total Rainfall (in) ¹	
10/31/2022	0.43	0.38	No bacteria samples collected		0.0
11/27/2022	1.0	0.2	1.0	0.2	2.0
1/19/2023	No bacteria samples collected		1.0	0.4	0.2
2/27/2023	1.2	1.1	0.9	0.7	1.9

¹Previous 14-day total excludes event daily total.

Ammonia timeseries (**Figure 6-3**) at Oakwood show increasing concentrations for the initial two samples, followed by a sharp increase on 10/31/2022 and slight decrease on 11/27/2022 in the

final sample. Ammonia concentrations at Leib were stagnant at approximately 5.0 mg/L. Again, the 2/27/2023 ammonia concentrations were significantly lower due to diluted samples from the higher-flow event.

Particulate Concentration in Fecal Coliform Samples from Leib (11/27/2022).

Figure 6-3
Ammonia as a Function of Time During Wet Weather Events

6.2 Chlorine Demand

Chlorine demand may be calculated from the dose response tests by subtracting TRC measured at a 30 or 60 second contact time from the initial chlorine dose. This approach recognizes the fast kinetics that occur in the water matrix after chlorine is added. Chlorine decay is calculated as the difference between TRC measured at a 30 or 60 second contact time and the final TRC measurement (30 minutes). In one instance, the Design Team used TRC at 15 minutes to calculate decay due to an error in measurement at 30 minutes.

Chlorine demand (with decay included) patterns at each facility and sample (**Figure 6-4**) indicate a positive correlation between chlorine demand and dose. The highest demands were observed at Leib, where doses ranged from 5 to 12 mg/L. Chlorine demands on 11/27/2022 at Leib also consistently decreased over the duration of the event. There was no clear and persistent relationship between demand and time for the 1/19/2023 weather event at Leib nor with the samples taken at Oakwood. As shown in **Figure 6-4**, the chlorine decay observed in the chlorine dose response tests was typically a small fraction of the total chlorine demand. Meaning that the majority of the difference between the TRC after a contact time and the chlorine dose stems from the chlorine demand exerted. Several outliers exist where chlorine decay comprises more than half of the chlorine demand (11/27/2022) at Leib, sample #1; dose = 12 mg/L and 2/27/2023 at Oakwood). Sample timing nor dose correlate with chlorine decay.

Figure 6-4
Chlorine Demand (Top) and Decay (Bottom) by Dose and Sample for All Wet Weather Events

The average chlorine demands per dose (i.e., all samples per dose included in average) are plotted as a function of dose (**Figure 6-5**) for all sampling events. Demand increases steadily between a dose of 2 mg/L and 5 mg/L at Oakwood before presenting with scattered results at doses of 6 mg/L and above. The demand response to dose at Leib are scattered and do not follow any consistent trend. The higher demand for the first Leib wet weather event, compared to the Oakwood events, could be attributed to the higher TSS values observed (average TSS of 100 mg/L vs. 52 mg/L and 47 mg/L for the Oakwood events).

Figure 6-5
Chlorine Residual as a Function of Dose (Oakwood and Leib)

The 1/19/2023 and 2/27/2023 events at Leib produce significantly lower demand responses at doses of 8 and 12 mg/L when compared to the 11/27/2022 event. Chlorine demand as a function of TOC (**Figure 6-6**) show higher demands at Leib correlating with higher constituent concentrations (TOC $R^2=0.57$). Positive, yet weaker correlations are apparent between chlorine demand and chemical oxygen demand (COD) (**Figure 6-7**) and TSS (**Figure 6-8**). However, there is no correlation between demand and TSS when isolating just the Leib samples.

Figure 6-6
Chlorine Demand as a Function of TOC During Wet Weather Events

Figure 6-7
 Chlorine Demand as a Function of COD During Wet Weather Events

Figure 6-8
 Chlorine Demand as a Function of TSS During Wet Weather Events

6.3 Chlorine Demand and Decay Characteristics

Chlorine dose and residual concentrations over time at Oakwood and Leib (**Figure 6-9** and **Figure 6-10, respectively**) show the time required for residual stabilization. There is no clear relationship between dose and time required for TRC to stabilize. The Design Team identified two unusual TRC measurements that are not consistent with the expected trends in TRC. The “Sample 1” TRC at a contact time of 1-minute and chlorine dose of 3 mg/L in Oakwood (**Figure 6-9**) is less than the subsequent TRC measurements at 3-minutes, 7-minutes, and 15-minutes. The “Sample 1” TRC at 7-minutes and chlorine dose of 12 mg/L in Leib (**Figure 6-10**) is less than the following TRC measurement at 15-minutes. While unusual, these data points were not removed prior to disinfection modeling as they do not compromise model results.

Figure 6-9
Total Residual Chlorine as a Function of Time for Oakwood Samples Separated by Dose.

Figure 6-10

Total Residual Chlorine as a Function of Time for Leib Samples Separated by Dose and Wet Weather Event.

6.4 Bacteria Modeling Approach

For wastewater disinfection and CSO discharge, it is common for the disinfection characteristics to follow a dual population type disinfection pattern. The total population of fecal coliform in the water can be thought of as having two distinct parts. The first part contains bacteria that are not associated with particles and are affected quickly by chlorine. The second part is more difficult to disinfect either because they are innately less sensitive to chlorine or because they are associated with particles or exist in clumps that prevent chlorine from reaching them as quickly. Therefore, there is usually an initial decrease of bacteria that happens quickly followed by a slower decrease in bacteria. The dose response for each part of the population can be described by a first order decay coefficient. These coefficients are determined by fitting the disinfection kinetics to **Equation 2**.

Equation 2 Dual Population Disinfection Model

$$N = N_o(1 - B)e^{(-K_d*ICT^m)} + (N_o \times B)e^{(-K_p*ICT)}$$

Where:

N = Fecal coliform concentration after applied ICT

No = initial fecal coliform concentration

β = Coefficient for particle based (“hard to inactivate”) fecal coliform population

k_p = the first order decay rate of “hard to kill” fecal coliform

k_d = the first order decay rate of “easy to kill” fecal coliform

ICT = Area under the chlorine dose response curve at a given contact time

m = Coefficient for magnitude of k_d

The Design Team developed models to best fit the observed fecal coliform counts. The Design Team optimized four parameters (β, k_d, k_p, and m) to produce a model that minimizes the residual sum of squares (RSS) (**Equation 3**) between modeled and observed data points. Model and observed fecal coliform counts are log transformed prior to RSS calculation to ensure the model doesn’t prioritize prediction at higher bacteria counts (where squared residuals are much greater).

Equation 3 Residual Sum of Squares (RSS) Formula

$$RSS = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

where:

y = modeled result

ŷ = observed data

n = number of observations

i = observation

An example disinfection model fit to observed fecal coliform counts is shown in **Figure 6-11**. There is a significant amount of variability in observed fecal coliform, which makes the modeling process difficult. The example model in **Figure 6-11** tends to underestimate fecal coliform at low ICTs and overestimate fecal coliform at high ICTs. The approach of minimizing residual sum of squares helps eliminate model bias, in which a model may consistently over or underestimate predictions and provides an objective statistical justification in determining a final model.

Figure 6-11
Example Disinfection Model Fit to Observed Fecal Coliform Counts

6.5 CSO Discharge Permit Limits

The disinfection facility must meet the National Pollution Discharge Elimination System (NPDES) permit requirements and state limits for fecal coliform. Wet weather goals are established for total residual chlorine and presented along with fecal coliform permit limits in **Table 6-4**. Additionally, the Oakwood NPDES permit includes a wet weather event average TRC goal of 1.5 mg/L. It is worth noting that the fecal coliform permit value during the recreation season is a maximum value of 400 CFU/100mL. Because exceeding this value would be a permit violation, the disinfection system must be able to consistently treat the wet weather flow to values under that maximum value. In other words, targeting a lower bacteria count will account for variability in influent water quality and system performance. Therefore, a target of 200 CFU/100mL of fecal coliform is utilized for some of the system performance criteria.

Table 6-4 NPDES TRC Goals and Fecal Coliform Limits

Period	Event Instantaneous Maximum TRC (mg/L)	Maximum Fecal Coliform (CFU/100mL)
November 1 - April 1	2.0	1,000
May 1 – October 31	3.0	400

The Design Team evaluated disinfection performance to several operating targets to ensure an appropriate design. The operating targets are based on NPDES bacteria permit limits (**Table 6-4**) and their associated log inactivation (**Table 6-5**). Log inactivation, along with actual bacteria counts, from the chlorine dose response testing is used to determine the site-specific ICT value that will be utilized to set the design criteria for the sodium hypochlorite storage and feed systems. When establishing the fecal coliform log inactivation values for selecting the ICT values, the Design Team used the following three conditions:

- Average undisinfected fecal coliform counts down to half of the recreational season max value (200 CFU/100mL)
- Maximum fecal coliform value measured down to the recreational season max value (400 CFU/100mL)
- Maximum fecal coliform value measured down to half of the recreational seasonal bacteria limit (200 CFU/100mL).

As shown in **Table 6-5**, using a target fecal coliform count of 200 CFU/100mL, compared to 400 CFU/100mL, increases the log inactivation required by 0.3, which provides a factor of safety to the design.

Table 6-5 Log Inactivation Permit Limits by Facility and Wet Weather Event

Inactivation Goal (IG)	Description	Oakwood			Leib		
		10/31	11/27	2/27	11/27	1/19	2/27
1	Average undisinfected bacteria to 200 CFU/100mL	3.8	4.1	2.5	4.0	3.2	3.5
2	Maximum bacteria to 400 CFU/100mL	4.4	4.2	2.3	4.4	3.2	3.5
3	Maximum bacteria to 200 CFU/100mL	4.7	4.6	2.6	4.7	3.5	3.8

When evaluating the disinfection performance results against the required inactivation goals (IG), the same IGs will be used for Oakwood (i.e. log inactivation from the 10/31/2022 testing). The 10/31/2022 IGs allow for a more conservative design as they are slightly higher at the maximum bacteria conditions than the 11/27/2022 testing. The 2/27/2023 IGs are considered outliers when trying to determine the high and average ICT values due to lower undisinfected bacteria counts. The 2/27/23 storm event data was used to determine the low ICT value for the system, which will impact the minimum capacity of the feed system. The second IG from 2/27/2023 (2.3) is lower than the first (2.5) because the average (70,600 CFU/100mL) and maximum (85,000 CFU/100mL) undisinfected bacteria counts used to calculate these IGs are similar in magnitude on a log scale. Therefore, the log inactivation goals for 2/27/2023 are more sensitive to differences in the target bacteria count. For Leib, the log inactivation requirements for the IGs are quite different between the three samples. The log inactivation required when starting with the maximum fecal coliform

counts from the 11/27/2022 sample is over 1 log inactivation greater than that for the 1/19/2023 sample. Applying the 11/27/2022 log inactivation requirements (4.4 and 4.7) to the 1/19/2023 disinfection model could be done, however that would yield exceptionally conservative ICT values as the undisinfected bacteria counts for the January wet weather event are approximately a log lower than that from the 11/27/2022 sample. As a result, the Leib wet weather events will use their own log inactivation values when determining the ICT value, and the highest one of the three will be utilized as the basis of design.

6.6 Bacteria Modeling Results

Disinfection efficacy is controlled by ICT, the product of the stabilized TRC and the contact time that the residual has with the water being disinfected prior to being neutralized. Typically, there is a strong, reproducible relationship between ICT and log inactivation of bacteria. The chlorine demand pattern discussed in the previous section illustrates how important water quality is to dose determination because it dictates the magnitude of the stabilized TRC concentration.

The Design Team determined design ICT values, and ultimately dosing requirements, by identifying the point at which modeled fecal coliform (or log inactivation) meet various NPDES permit -based log inactivation requirements.

Modeled and observed log inactivation (**Figure 6-12**, **Figure 6-14**, and **Figure 6-16**) and fecal coliform (**Figure 6-13**, **Figure 6-15**, and **Figure 6-17**) at Oakwood are expressed as a function of ICT and differentiated by sample event. Models fit to observed fecal coliform at Oakwood across all three sampling events (per storm) are expressed as log inactivation (**Figure 6-18**) and bacteria count (**Figure 6-19**), and it is these two figures that are used to determine the ICT values for a given facility. These two figures are used, rather than the model results for the individual samples taken during a wet weather event, because the combined models better represent the overall disinfection results for the samples collected and tested, and do not over emphasize the best or worst results.

Disinfection models expressed as log inactivation and bacteria count by sample for Leib are presented in **Figures 6-20** through **6-25**. Models fit to observed fecal coliform at Leib across all three samples (per storm) are expressed as log inactivation (**Figure 6-26**) and bacteria count (**Figure 6-27**). Like **Figure 6-18** and **Figure 6-19** for Oakwood, it is **Figure 6-26** and **Figure 6-27** that are utilized to determine the ICT value for the facility. The log inactivation permit limits in accordance with **Table 6-5** and bacteria count targets (200 CFU/100mL and 400 CFU/100mL) are represented by horizontal red lines.

ICT requirements may be discerned from **Figures 6-12** through **6-27** by reading the ICT value at each intersection between a modeled curve and permit limit. For example, an ICT of approximately 35 mg-min/L is required to meet the least conservative log inactivation permit limit of 3.8 at Oakwood on 10/31/2022 for “Sample 1.”

A comparison of ICT requirements required to reach the various inactivation goals (IG) for the event-based models (**Figures 6-18 and 6-19**, and **Figures 6-26 and 6-27**) are summarized in **Table 6-6** for both Oakwood and Leib.

Table 6-6 Summary of ICT Requirements For Event-Models by IG

Location	Event	Inactivation-Based ICTs				Count-Based ICTs		
		IG1	IG2	IG3	Max	400	200	Max
Oakwood	10/31/2022	38	50	56	56	49	55	55
	11/27/2022	65	96	113	113 ²	87	104	104
	2/27/2023	44 ¹	90	118	118 ²	4 ⁵	5	5
Leib	11/27/2022	47 ³	87	127	127 ⁴	87	127	127
	1/19/2023	21	21	33	33	20 ⁶	32	32
	2/27/2023	131	131	157	157 ⁴	129	155	155

¹ Median value used to determine design “average” Oakwood ICT

² Values used to determine design “high” Oakwood ICT

³ Median value used to determine design “average” Leib ICT

⁴ Values used to determine design “high” Leib ICT

⁵ Value used to determine design “low” Oakwood ICT

⁶ Value used to determine design “low” Leib ICT

The ICT values for Oakwood ranged from 38 to 118 across the various IGs. Higher ICTs of 113 (IG3 on 11/27/2022) and 118 (IG3 on 2/27/2023) were driven by higher stabilized fecal coliform counts and lower undisinfected counts, respectively (**Figure 6-19**). This restricted distribution of fecal coliform resulted in a more conservative model that failed to disinfect CSO as quickly as the 10/31/2022 model for Oakwood. There were no distinguishable characteristics in water quality between events. The ICT values for Leib ranged from 21 to 157 across the various IGs. Again, there were no patterns in water quality at Leib that explain the ICT variation.

The Design Team recommends a “high” ICT value of 120 mg-min/L for Oakwood and 142 mg-min/L for Leib. The Oakwood ICT value is based on achieving a permit log inactivation of 4.7 and extracted from the 11/27/2022 and 2/27/2023 event-wide models presented in **Figure 6-18** (rounded up to the nearest 10 mg-min/L). The Leib ICT value is based on an average of the two largest ICTs calculated (127 and 157). Accordance with log inactivation permit limits resulted in more conservative (higher) “high” ICT values and were thus selected over fecal coliform permit limits.

The Design Team recommends “average” ICT values of 50 mg-min/L for both Oakwood (**Figure 6-18**) and Leib (**Figure 6-26**). These are intended to represent “average” conditions and are derived from the median (middle) ICT across the three samples required to meet IG1, rounded up to the nearest 10 (**Table 6-6**).

The Design Team recommends “low” ICT values of 4 mg-min/L for Oakwood (**Figure 6-19**) and 20 mg-min/L for Leib (**Figure 6-27**). These are intended to represent a bare minimum for disinfection and will ensure a flexible feed system capable of disinfecting a range of water quality and flow. The values are derived from the ICTs for count-based disinfection to 400 CFU/100mL, which are the lowest modeled ICTs found in the study (**Table 6-6**).

7.0 Conclusion

The water industry is using an integrated CT approach to optimize chemical disinfection processes as it has been shown to best represent the disinfectant and bacteria inactivation kinetics observed within the disinfected water matrix. The Design Team utilized an integrated CT approach to size the sodium hypochlorite disinfection feed and storage systems for the Oakwood and Leib CSO treatment facilities. As part of the scope for this project, The Design Team collected six undisinfected samples during three wet weather events from both facilities and had multiple chlorine dose response test performed. The data from these tests resulted in “high” ICT values of 120 mg-min/L for Oakwood and 142 mg-min/L for Leib, “average” ICT values of 50 and 50 mg-min/L for both Oakwood and Leib, and “low” ICT values of 4 mg-min/L for Oakwood and 20 mg-min/L for Leib. Utilizing the ICT values selected from the modeling results described above, is discussed in TM-20. The Design Team recommends that GLWA begin collecting undisinfected wet weather bacteria counts throughout the year to better understand the seasonal variability of the undisinfected water quality characteristics, which so greatly impact disinfection performance.

Based upon sampling and analysis performed to date, ICT values have been determined to establish the design criteria for the disinfection storage and feed systems. In order to further refine the ICT values and better characterize impacts of seasonal effects on water quality, additional sampling and analysis of untreated wet-weather flows should be performed. This should include blending samples to better characterize the untreated flow for each facility after future collection system tie-ins have been made.

8.0 Next Steps

The following are next steps required to advance the disinfection system improvements at Oakwood and Leib.

- It is recommended that GLWA obtain additional untreated wet-weather water quality data (e.g., undisinfected bacteria, TSS, COD, ammonia at the beginning, middle, and end of each storm event) for both facilities for approximately one year to further refine chlorine demand/decay evaluation results and ICT values. At the conclusion of the sampling program, the results can be discussed with CDM Smith.
- Consider sampling at various depths during storm events to further validate samples are representative.
 - For Oakwood, it is recommended that GLWA blend untreated wet-weather samples (beginning, middle and end of each storm event) from the Northwest Interceptor (NWI) and Oakwood subdistrict (currently discharges to OKW) and analyze them for undisinfected bacteria and TSS. In addition, GLWA ought to perform periodic chlorine dose response tests on the blend untreated wet-weather samples. The recommended blend is four parts NWI to one part Oakwood to simulate future collection system conditions.

Section 1

Introduction

This section provides a brief description of site background and the overall work plan organization.

1.1 Project Background

The Great Lakes Water Authority (GLWA) has an Interim Wet Weather Operating Plan (IWOP) that optimizes the use of 183 miles of regional pipelines, the Water Resources Recovery Facility (WRRF), remote pumping and combined sewer overflows (CSO) treatment facilities located in Detroit, Michigan. The Rouge River watershed's 127 stream miles naturally drain 466 square miles of Detroit's west side and its northwestern suburbs and has been greatly influenced by the development history of metropolitan Detroit. Development of the river's natural floodplain has led to typical watershed urbanization issues, including pollution from various sources, flooding, high streamflow variability and habitat degradation. It is one of 43 Areas of Concern within the Great Lakes watershed. The Great Lakes Water Quality Agreement (GLWQA) of 1978 between the United States and Canada requires the development of a Remedial Action Plan for each Area of Concern. Starting in 1992, Wayne County led the Rouge River restoration initiative through the support of the USEPA Rouge River National Wet Weather Demonstration Project funding. Numerous CSO control, stormwater management, stream restoration, and contaminated sediment projects were completed across Wayne, Oakland, and parts of Washtenaw Counties from 1992 to 2008, including eleven combined sewer Retention Treatment Basins, six Sanitary Retention Basins and one Screening and Disinfection Facility. These improvements reduced CSO discharge volume by 4 billion gallons per year and resulted in a 50% reduction in CSO impacted stream miles. These investments combined with subsequent projects by Detroit Water & Sewerage Department (DWSD) through 2013 have dramatically improved dissolved oxygen levels and restored native fish species and other aquatic life to the river. In addition, bacteria levels decreased significantly during wet weather. However, not all sewer overflows were addressed, and the river is still subject to discharges from 17 yet uncontrolled CSOs, which contribute to exceedances of water quality standards for bacteria and dissolved oxygen.

As part of the GLWA Wastewater Master Plan, the Oakwood Retention Treatment Basin (RTB) and the Leib Screening and Disinfection Facility (SDF) have been identified as sources of uncontrolled CSO discharges during wet weather events. The primary objective of this study is to optimize chlorine disinfection processes during a wet weather events at both the Oakwood RTB and Leib SDF.

1.2 Work Plan Organization

This bench-scale work plan is organized as follows:

1. **Section 1: Introduction** – Provides a background of the study, organization of the work plan, and general information about the study.

2. **Section 2: Scope, Objectives, and Technical Approach** – Provides a brief description of the scope of work to be performed by CDM Smith, the project objectives, and the overall technical approach.
3. **Section 3: Field and Laboratory Methods** – Describes the field procedures to collect site-specific water at the WWTF for bench-scale testing and details pertinent to the experimental setup and bench testing sampling and analysis plan.
4. **Section 4: Sampling and Analysis plan**– Presents the sampling and analysis plan that will be executed to achieve the project-specific objectives.
5. **Section 5: Reporting**– Describes the task- and overall project-specific reporting requirements for implementation of the bench-scale study.
6. **Section 6: Health and Safety** – Describes the health and safety procedures to be followed by field and laboratory personnel supporting this project.
7. **Section 7: Waste Management** – Summarizes how waste generated as part of this bench-scale study will be managed and disposed

This page intentionally left blank.

Section 2

Scope, Objectives, and Technical Approach

This section describes the overall scope of work, project objectives, and technical approach.

2.1 Scope of Work

This laboratory testing protocol includes chlorine dose response testing on water collected from the Oakwood RTB and Leib SDF effluent prior to disinfection. Sampling will occur at three separate time points (initial, peak, and final) of a wet weather event to evaluate the chlorine dose response under different water quality conditions. Testing will be performed using a single-step chlorine dosing scheme. Free chlorine residual, total chlorine residual, and fecal coliform will be evaluated at three different chlorine doses and five different chlorine contact times. Based on the log-inactivation results of fecal coliforms from the bench-scale testing, CDM Smith will make recommendations on the chlorine dose that should be implemented to meet disinfection goals.

2.2 Overall Objectives

The overall objectives of the bench-scale study include the following:

- Determine doses and contact times for chlorine that are most effective for fecal coliform treatment at each site; and
- Determine chlorine dose response under different water quality conditions.

2.3 Overall Technical Approach

Water samples from Oakwood RTB and Leib SDF will be collected during a wet weather event at three different sample points (initial, peak, and final) for each storm event. Samples will be collected simultaneously from both sites during a wet weather event. Samples will be collected in 5-gallon plastic jerricans and shipped with CDM Smith's Research and Testing Laboratory (RTL) on ice using FedEx priority first overnight (8:30 AM arrival). If the FedEx shipment is delayed for any reason, there will be a conference call with the technical lead to discuss remedial action and if there will be a reduction in testing scope will be necessary.

Chlorine dose bench testing is expected to take two full days. Upon sample arrival, testing will be performed on the three sample points from one site and the samples from the other site will be stored in the walk-in fridge at 4°C to be tested the following day. Due to testing time constraints, samples collected on Wednesday or Thursday will be shipped to the RTL and kept cold in the walk-in fridge to be tested the following Monday. Sample collected on a Friday will be kept cold in coolers with ice over the weekend and shipped to the RTL the following Monday with new ice.

Samples will not be collected for the subsequent wet weather event until results from the first event is received, analyzed, and checked for quality assurance and quality control (QA/QC). This delay is recommended to account for any adjustments in chlorine dose or contact time conditions.

Upon receipt at the RTL, the sample temperature will be collected and baseline water quality parameters measured (**Section 3.4.1**). Samples will then be brought to room temperature at or near 20°C and testing will begin immediately. A 5-minute and 30-minute chlorine demand pre-test will be performed at the lowest and highest disinfectant doses to confirm the presence of chlorine residual.

Individual bench disinfection tests will then be executed, and samples will be collected for analysis for each dose and timepoint. Samples will be collected and analyzed for pertinent parameters at the RTL and/or submitted to a contracted laboratory. **Table 2-1** outlines the analytical sampling matrix.

Detailed experimental procedures can be found in **Section 3**. Details relevant to the experimental setup and sampling and analysis plan are provided in the subsequent sections.

Table 2-1. Analytical Matrix

Section 3

Field and Laboratory Methods

This section describes the procedures that will be utilized to collect site-specific water samples. In addition, details pertinent to the experimental setup of the bench-scale studies are provided herein.

3.1 Sample Collection

Prior to sample collection, local CDM Smith field personnel will coordinate with Oakwood RTB and Leib SDF staff to access the site. A kick-off conference call with CDM Smith RTL and field sampling personnel will be held to coordinate proper water collection procedures and specify the volumes of water required for bench testing.

Prior to sampling, CDM Smith RTL personnel will ship a sampling kit containing the equipment required for collection to the field sampling staff. The kit will be in a hard side cooler and contain Ziploc™ bags for ice, a centrifuge tube with tap water labeled “temperature blank”, the necessary number of 5-gallon jerrican and a Chain of Custody (COC) form (**Attachment A**).

For each round of wet weather testing, approximately thirty gallons (six 5-gallon jerricans) of sample will be required for testing. The COC form filled out for the jerrican in each cooler will be completed by the sampler, placed in a Ziploc™ bag and taped to the inside lid of the sample cooler. For the first sample shipment only, a sample shipment memo (SSM) (**Attachment B**) is required. The SSM will be completed by the sampler and submitted by email to the CDM Smith RTL Chemical Hygiene Officer (CHO) Mary Lou Fox (FoxML@cdmsmith.com) and the CDM Smith RTL Technical Lead, Dung Nguyen (nguyendd@cdmsmith.com) prior to sample collection.

The jerrican used for sample collection will be triple rinsed with sample water and then returned to the site. That is, a small amount of sample (approximately 500 mL) will be dispensed into a given jerrican, thoroughly shaken and then dumped out; this is repeated three times before collecting the actual sample.

Samples will be collected in such a way that limits potential for changes in water quality. Proper sampling techniques will be employed per Standard Method 1060 (**Attachment C**). These procedures include completely filling the jerrican such that there is no remaining headspace. Multiple grab samples will be composited into a single jerrican using a pail fixed to a rope for each sample point in the wet weather event. The sample collection device will be disinfected with 70% isopropanol or 10% bleach solution between sample points to prevent cross contamination. To prevent photooxidation and limit additional microbial growth, samples will be kept on ice in a cooler while sampling and not exposed to sunlight unnecessarily or for extended periods of time. The jerrican will be numbered in the order of sample collection with the following naming convention: LOCATION-YYYYMMDD-SAMPLE POINT. For example, OAKWOOD-20221001-INITIAL. This jerrican identifier will also be what is entered on the COC. One jerrican will be placed in each cooler. Ice will be filled in double bagged sealable

Ziploc™ bags to fill the remaining space of each cooler. The double bagged ice fill be filled as shown in **Figure 3-1**, where the seals are oriented opposite each other to prevent leaking. Double-bagged ice will be placed on the bottom of the cooler, in-between sample and cooler, and on the top of samples.

Samples will be shipped the day of collection overnight on ice directly to CDM Smith's RTL (address below). If samples cannot be shipped out the day of collection, samples will be stored at 4°C until they can be shipped. Any storage of samples prior to shipment will be communicated by field staff to the CDM Smith RTL staff. Each cooler must include a temperature blank and proper chain-of-custody (COC) documentation detailing the number of jerricans, time and date of sample collection. The COC form is included in Appendix B. When sampling is complete, the sampler will email Dani Tran (trandn@cdmsmith.com), cc Dung Nguyen (nguyendd@cdmsmith.com) and provide information on the conditions at the facility at the day of sampling (water flows, any unique aspects of operations, and the procedures of sample collection). The sampler will also email the tracking number to Dani Tran on the day the samples are shipped out. Each cooler will contain a temperature blank (tap water in a poly container), which will be used to evaluate temperature upon receipt of the sample water. Samples will only be shipped to the CDM Smith RTL on Mondays, Tuesdays, Wednesdays and Thursdays. Samples will be shipped to the following address:

ATTN: Dani Tran
14432 SE Eastgate Way, Suite 100
Bellevue, WA 98007
Office: (425) 519-8321
Cell: (206) 370-9472

Figure 3-1 Double-bagging technique to prevent leaking

3.2 Shipment to Outside Laboratories

After bench testing, CDM Smith will send appropriate samples to an external lab (AMTEST, or similar) for the analysis of fecal coliform, total suspended solids, and total organic carbon. Each cooler will be dropped off or picked up via courier on ice containing a temperature blank and a COC specifying which analyses will be performed. Unless otherwise specified, all results will be reported within a standard turnaround time (TAT) as determined by the external lab.

3.3 Laboratory Testing

This section describes the operational details for bench testing. The testing window for wet weather events is expected to start in October and end in late December/early January before the freezing temperatures affect storm water flows, for up to two wet weather events. For each wet weather event, there are 18 unique test conditions (9 for each site location, with 3 sample points and 3 chlorine doses). Therefore, multiple tests will need be executed concurrently. Three CDM Smith staff members will be needed to support the execution of the experiment. A detailed example of concurrent disinfection study execution is further explained below, and a reference is shown in **Table 3-2**.

Table 3-1. Experimental Matrix

Water Types	# of Wet Weather Events	Sample Points	Chlorine Doses ¹ (mg/L)	Chlorine Contact Times ¹ (mins)	Analyses
Oakwood RTB & Leib SDF	2	Initial, Peak, Final	0	0	Fecal coliform COD TOC TSS pH Temperature Ammonia Color (apparent) UV-254 (unfiltered) Free chlorine Total Chlorine

¹ Subject to change based on disinfection performance

Notes: COD- chemical oxygen demand, TOC – total organic carbon, TSS- total suspended solids, UV- ultraviolet 254 nm

3.3.1 Chlorine Dose Testing

A concentrated sodium hypochlorite stock will be prepared from analytical grade sodium hypochlorite. The stock will be prepared at a concentration such that the volume used to spike the sample is less than 1% of the test volume. The concentration of the stock solution will be confirmed in triplicate before testing, and spiking volumes will be adjusted to reflect the actual chlorine concentration in the stock.

The jerricans with sample water will be thoroughly shaken to ensure homogeneous distribution of particles. Each test will require two liters (L) of well-mixed sample be collected in a 4-L beaker with a

large stir bar. The sample will be placed on a stir plate and mixed so that particles are evenly suspended.

Aseptic technique will be used for collecting samples for microbial analysis. All labware will be either sterile or disinfected prior to use 70% isopropanol or 10% bleach solution. Samples will be collected using sterile 50 mL serological pipettes. After disinfection studies are complete, the samples will be picked up by a courier service or dropped off to a local analytical laboratory to maintain sampling holding time.

Sodium hypochlorite will be dosed using a 10,000 mg/L Cl_2 stock solution from analytical grade sodium hypochlorite. Stock solutions will be used to dose the water already dispensed into the test beaker. Each test condition will have a timer assigned to it for ease of noting time elapsed, and the timer will be started as soon as the sodium hypochlorite is added. Due to the number of tests being performed for each site location, the 9 test conditions for each site will be executed in the staggered fashion shown in **Table 3-2**. The first test condition will be dosed with chlorine and the time of day will be recorded and timer will be started. After 1-minute, samples will be collected using sterile serological pipettes. Two people will be responsible for filling fecal coliform bottles, and testing free and total chlorine, while a third person will be recording sample collection times and facilitating general organization throughout the testing. This process will be repeated at 3, 5, 7, 15 and 30 minutes (subject to change). After the 15-minute contact time is collected from the first test condition, the second test condition will be dosed with chlorine. Samples will be collected from the second jar similar fashion to the first jar at 1, 3, 5, and 7 minutes before returning to the first jar to collect the 30-minute sample. This is repeated for all subsequent jar tests.

Table 3-2 Example sampling protocol for concurrent disinfection studies

D-dose with hypochlorite

X-sample for fecal coliform and F&T chlorine

✓-sample for fecal coliform, Ammonia, COD, TOC TSS, pH, temp and F&T chlorine

3.3.2 Baseline and Water Chemistry Parameters

Measurements for COD, pH, temperature, ammonia, color (apparent), UV-254 (unfiltered), free chlorine, and total chlorine will be performed the same day the sample arrives. Samples for TOC, TSS, and fecal coliform will be subsampled from the carboy into the appropriately preserved sample bottles provided by the subcontracted analytical laboratory and shipped on ice for analysis.

3.3.3 Free and Total Chlorine

Free chlorine is the chlorine still available to react (i.e., disinfect; OCl) and total chlorine is comprised of both combined (i.e. chloramines) and free chlorine. Both are measured in order to calculate demand. Both free and total chlorine will be measured at the RTL using HACH methods 8021 and 8167, respectively. The detection limit for the free and total chlorine are 0.2 mg/L. Dilutions will be made accordingly.

3.3.4 Microbiology

Samples will be collected for microbial analysis to assess disinfection of fecal coliform. AmTest will perform the fecal coliform analysis. Microbial data will be plotted as log inactivation versus concentration-time (CT, Samples will be collected for microbial analysis to assess disinfection of fecal coliform. AmTest (or similar laboratory) will perform the fecal coliform analysis. Microbial data will be plotted as log inactivation versus concentration-time (CT, mg/L*min).

This page intentionally left blank.

Section 4

Sampling and Analysis Plan

This section provides details pertinent to the sampling and analysis for each bench-scale test. Specifically, the type of analytes collected, sampling frequency performed, and laboratory methods employed are discussed herein.

4.1 Analytical Testing

Samples for fecal coliform, free chlorine, and total chlorine residual will be collected at approximately 1, 3, 7, 15, and 30 minutes. pH, temperature, TOC, TSS, ammonia, color (apparent), UV-254 (unfiltered) will be evaluated for baseline. pH and temperature will be monitored with a probe and are important for determining the chlorine kinetics. TOC, TSS, color, and UV-254 will be monitored as they exert some chlorine demand. Ammonia will react with free chlorine to form chloramines. The analytical details of these parameters are detailed in **Table 4-1**.

Table 4-1 Analytical Methods

Parameter	Laboratory	Method	Method Detection Limit	Reporting Limit	Volume Required (mL)	Preservatives	Hold time
pH	RTL	Probe	-	-	3	N/A	Immediate Analysis
Temperature	RTL	Probe	-	-	3	N/A	
TSS	AMTEST	SM2540D	4.44 mg/L	10 mg/L	100	N/A	7 day
Ammonia	RTL	HACH Method TNT830	0.003 mg/L	0.05 mg/L	100	0.5mL 50% H2SO4	28 day
COD	RTL	SM 5220	3-150mg/L (LR)	-	2	N/A	Immediate Analysis
TOC	AMTEST	SM 5310B	0.025 mg/L	0.25	2	N/A	Immediate Analysis
Color (Apparent)	RTL	SM 2120	-		15	N/A	Immediate Analysis
UV 254 (un-filtered)	RTL	SM 5910	-		30	N/A	Immediate Analysis
Fecal Coliform	AMTEST	SM9223B		1CFU/100mL	100	Sodium Thiosulfate	6 hours
Free Chlorine	RTL	HACH Method 8021	0.02-2 mg/L		3	N/A	Immediate Analysis
Total Chlorine	RTL	HACH Method 8167	0-2 mg/L		30	N/A	

Notes: NA – not applicable, RTL – Research and Testing Laboratory, SM – Standard Methods, mg/L – milligrams per liter, TOC – total organic carbon, TSS – total suspended solids, UV 254 – ultraviolet absorbance at 254 nanometers

4.2 Quality Assurance and Quality Control (QA/QC)

Experimental replication will be performed at a rate of 1 in 10 (10%). Analytical replication will be collected at a rate of 1 in 20 (5%). Appropriate quality control procedures will be utilized for analysis, including blanks, laboratory control standards, calibration standards, and standard checks for each analytical run.

4.2.1 Interferences

This project will include analyses that can detect individual colonies of bacteria. Therefore, it is important to minimize cross contamination or interferences. The following are potential sources of interferences during sampling:

- Improper sample collection through the use of contaminated equipment and personnel, disturbance of the sampling site during collection, and sampling in an obviously disturbed area.
- Improper preservation and/or failure to preserve sample containers requiring preservation.
- Cross-contamination can occur if sample containers have not been properly sanitized and stored.
- Utilizing sampling materials or containers with inappropriate materials (e.g., plastic in the place of glass or stainless steel).
- Exceeding the hold times established for the analyte.

Review all of the procedures and quality assurance documents carefully.

This page intentionally left blank.

Section 5

Reporting

The RTL will validate the data collected during the disinfection study and provide plots of chlorine demand and decay and fecal coliform activation over time. All samples will be analyzed in a standard turnaround time (two to three weeks). The data from the bench testing will be entered into a project database by the RTL staff, as well as develop graphs of notable data trends. The fecal coliform, free chlorine, and total chlorine data will be used to generate graphs illustrating log inactivation vs. integrated concentration time (ICT) and fecal coliform vs. ICT, which will then be utilized with the historical plant data to determine the required ICT value to meet disinfection goals.

Up to three one (1) hour conference calls will be held between the RTL and technical leader to discuss findings and recommendations. A spreadsheet summary of all laboratory activities performed, discussion of notable results, and implications for disinfection with respect to anticipated regulations will be provided as a final deliverable. Specifically, CDM Smith will evaluate chlorine doses over the three sample points at each site location. A technical memorandum or report of the bench testing results will not be provided by the RTL staff.

This page intentionally left blank.

Section 6

Health and Safety

Field sample collection will be conducted by site staff in accordance with the site-specific health and safety procedures. RTL staff will adhere to the Chemical Hygiene Plan, Biosafety Level 2 protocols, and the project health and safety plan for execution of experiments. A health and safety plan (HASP) will be prepared and reviewed with the CHO prior to any lab activities; all relevant personnel will review, acknowledge, and sign off on this before work begins. All safety considerations will also be discussed during the kickoff meeting held prior to commencement of laboratory work.

This page intentionally left blank.

Section 7

Waste Management

All water samples will be properly disinfected disposed on site by the RTL. Chemical reagents in excess of those required for the experiments described herein will be disposed of by a waste disposal subcontractor in accordance with all relevant local, state, and federal regulations.

This page intentionally left blank.

Sample Shipment Memo

Memorandum

To: Whom It May Concern

*From: Jennifer Hooper, CDM Smith Research and Testing Laboratory
(Bellevue, WA)*

Date: 5/22/20

Subject: Procedure for Samples Shipping to Treatability Lab

This memo contains procedures for sending samples to the CDM Smith Research and Testing Laboratory (RTL). It is intended to be used by anyone who sends environmental samples to the ETL, regardless of whether they are CDM Smith employees or not.

RTL staff or project managers will provide this memo to the sender prior to the sample shipment. Upon receipt, the sender must read it carefully and fill it out to the best of their knowledge before preparing the samples for shipping.

Once the memo is complete, it must be submitted to Jennifer Hooper or Zoom Nguen for review. Upon the completion of review, the sender will be informed if the sample(s) is approved to be shipped or if additional information is required prior to shipping. A completed and approved copy of this memo must be shipped together with the sample(s) to the lab.

Before Shipping

It is the sender's responsibility to classify the samples to be shipped. If the samples are classified as Dangerous Goods, the sender must have applicable training on DOT and IATA regulations before initiating the shipment. For example, Fedex will not allow shipping of dangerous goods unless the sender has been trained on proper procedures. Furthermore, there can be significant penalties (up to \$50,000 per violation, per day) that can be imposed by DOT on the sender PERSONALLY (not just the company) if noncompliant shipments are offered by a shipper.

CDM employees should be familiar with CDM policy, located here:

http://cdmweblegacy/h&s/documents/hazmat_transport.doc
http://cdmweblegacy/h&s/hazmat_transport.html

Sample Shipment Procedures

1. Communicate with Treatability Laboratory Management regarding below sample information and desired scope of work.

Charles Schaefer, ETL Director	425-519-8300	schaeferce@cdmsmith.com
Jennifer Hooper, Technical Lead, Water and Wastewater		hooperjl@cdmsmith.com
Zoom Nguyen, Technical Lead, Remediation		nguyendd@cdmsmith.com
Mary Lou Fox, Chemical Hygiene Officer		foxml@cdmsmith.com

2. Receive written approval from Laboratory Management for sample shipment (i.e. this memo, once completed and approved).
3. All the sample containers must bear a readable label with the sample name and contents, the related project name, the sender's name and company, the sample collection date, and any other appropriate sample information.
4. Prepare shipment per DOT and IATA regulations. Include a completed Chain-of-Custody form.
5. Send samples via overnight courier to the RTL:
CDM
Attn: Janelle Amador
14432 SE Eastgate Way, Suite 100, Bellevue, WA 98007
6. Inform Laboratory Management of shipping status and provide tracking number.

Sample Information Required Prior to Shipment

1. Source

Please check all of the following boxes that are applicable regarding the nature of the sample:

- | | | |
|--|--|---|
| ☐ Groundwater | ☐ Subsurface soil | ☐ Industrial Waste Water |
| ☐ Surface water | ☐ Surface soil | ☐ Municipal Waste Water |

2. Contaminants

Please check all of the following boxes that are applicable regarding contaminants in the sample:

- | | | |
|---|---|--------------------------------------|
| ☐ Chlorinated Solvents | ☐ Petroleum Hydrocarbons | ☐ Metals |
| ☐ Radioactive Substances | ☐ Pesticides/PCBs | ☐ Perchlorate |
| ☐ Unknown | | |

Please list specific contaminants: _____

3. Hazards Information

Based on the MSDS or other sources of the sample hazards information, please check all of the following boxes that are applicable.

- | | | |
|------------------------------------|------------------------------------|--|
| ☐ Flammable | ☐ Toxic | ☐ Unknown, but is potentially hazardous |
| ☐ Reactive | ☐ Corrosive | ☐ None apply |

Notes: _____

4. Potential Headspace Gas Accumulation

- Sample will be shipped on ice? ☐ Yes ☐ No
- Any potential for gas generation/accumulation in the sample container during the transportation? ☐ Yes ☐ No
- If yes to the question above, please specify what are the gases could be encountered in the container upon receipt:

5. Sample handling information

- Does the sample require refrigeration on arrival? ☐Yes ☐No
- Will a temperature blank be included to verify appropriate temperature control during shipping? ☐Yes ☐No
- Does the sample require protection from oxygen contamination (i.e., should the containers be opened only in an anaerobic chamber)? ☐Yes ☐No

If yes:

- Water samples must be shipped in containers of 1L or smaller
- Soil cores must be no more than 16" long. Other containers should be no larger than 15" x 8" x 8".

6. Additional Sample Information

Please indicate if any of the following sources of information are included for the sample.

- ☐SDS ☐Product Sheet ☐Source Materials Information
☐No Additional Info Available

Notes: _____

Sample Sender's Name (print): _____

Sample Sender's Signature: _____

Date: _____

Approved for shipping? ☐ Yes, ☐ No,

☐ Additional Information is needed, which includes:

Approved by: _____ (Print)

_____ (Signature)

Date: _____

Appendix C

Standard Method 1060 for Sample Collection

1060 A. Introduction

It is an old axiom that the result of any testing method can be no better than the sample on which it is performed. It is beyond the scope of this publication to specify detailed procedures for the collection of all samples because of varied purposes and analytical procedures. Detailed information is presented in specific methods. This section presents general considerations, applicable primarily to chemical analyses. See appropriate sections for samples to be used in toxicity testing and microbiological, biological, and radiological examinations.

The objective of sampling is to collect a portion of material small enough in volume to be transported conveniently and yet large enough for analytical purposes while still accurately representing the material being sampled. This objective implies that the relative proportions or concentrations of all pertinent components will be the same in the samples as in the material being sampled, and that the sample will be handled in such a way that no significant changes in composition occur before the tests are made.

Frequently, the objective of sampling and testing is to demonstrate whether continuing compliance with specific regulatory requirements has been achieved. Samples are presented to the laboratory for specific determinations, with the sampler being responsible for collecting a valid and representative sample. Because of the increasing importance placed on verifying the accuracy and representativeness of data, greater emphasis is placed on proper sample collection, tracking, and preservation techniques. Often, laboratory personnel help plan a sampling program in consultation with the user of the test results. Such consultation is essential to ensure selected samples and analytical methods provide a sound and valid basis for answering the questions that prompted the sampling and that will meet regulatory and/or project-specific requirements.

This section addresses the collection and preservation of water and wastewater samples; the general principles also apply to the sampling of solid or semisolid matrices.

1. General Requirements

Obtain a sample that meets the requirements of the sampling program and handle it so it does not deteriorate or become contaminated or compromised before it is analyzed.

Ensure that all sampling equipment is clean and quality-assured before use. Use sample containers that are clean and free of contaminants. Bake at 450°C all bottles to be used for organic-analysis sampling.

Fill sample containers—without prerinsing—with sample; prerinsing results in loss of any pre-added preservative and sometimes

can bias results high when certain components adhere to the sides of the container. Depending on determinations to be performed, fill the container full (most organic compound determinations) or leave space for aeration, mixing, etc. (microbiological and inorganic analyses). If a bottle already contains preservative, take care not to overfill the bottle, as preservative may be lost or diluted. Except when sampling for analysis of volatile organic compounds or radon, leave an air space equivalent to approximately 1% of the container volume to allow for thermal expansion during shipment.

Special precautions (discussed below) are necessary for samples containing organic compounds and trace metals. Because many constituents may be present at low concentrations (micrograms or nanograms per liter), they may be totally or partially lost or easily contaminated when proper sampling and preservation procedures are not followed.

Composite samples can be obtained by collecting over a period of time, depth, or at many different sampling points. The details of collection vary with local conditions, so specific recommendations are not universally applicable. Sometimes it is more informative to analyze numerous separate samples instead of one composite so variability, maxima, and minima can be determined.

Because of the inherent instability of certain properties and compounds, composite sampling for some analytes is not recommended where quantitative values are desired (examples include oil and grease, acidity, alkalinity, carbon dioxide, chlorine residual, iodine, hexavalent chromium, nitrite, volatile organic compounds, radon-222, dissolved oxygen, ozone, temperature, and pH). In certain cases, such as for BOD, phenolics, sulfite, and cyanide, composite samples are routinely required by regulatory agencies. Refrigerate composite samples for BOD, nitrate, ammonia, TKN, TSS, COD, and TOC.

Sample carefully to ensure that analytical results represent actual sample composition. Important factors affecting results are the presence of suspended matter or turbidity, the method chosen for removing a sample from its container, and the physical and chemical changes brought about by storage or aeration. Detailed procedures are essential when processing (blending, sieving, filtering) samples to be analyzed for trace constituents, especially metals and organic compounds. Some determinations can be invalidated by contamination during processing. Treat each sample individually with regard to the substances to be determined, the amount and nature of turbidity present, and other conditions that may influence the results.

Carefully consider the technique for collecting a representative sample and define it in the sampling plan. For metals, it often is appropriate to collect both a filtered and an unfiltered sample to differentiate between total and dissolved metals present in the matrix. Be aware that some metals may partially sorb to filters. Beforehand, determine the acid requirements to bring the pH to <2 on a separate sample. Add the same relative amount of acid to all samples; use ultrapure acid preservative to prevent contamination. Be sure that the dilution caused by acidifying is negligible or sufficiently reproducible for a dilution correction factor. When

filtered samples will be collected, filter them in the field, if possible, or at the point of collection before preservation with acid. Filter samples in a laboratory-controlled environment if field conditions could cause error or contamination; in this case, filter as soon as possible. Often, slight turbidity can be tolerated if experience shows that it will cause no interference in gravimetric or volumetric tests and that its influence can be corrected in colorimetric tests, where it has potentially the greatest interfering effect. Sample collector must state whether the sample has been filtered.

Make a record of every sample collected and identify every bottle with a unique sample number, preferably by attaching an appropriately inscribed tag or label. Document sufficient information to provide positive sample identification at a later date, including the unique sample identification number, the name of the sample collector, the date, hour, exact location, and, if possible, sample type (e.g., grab or composite) and any other data that may be needed for correlation, such as water temperature, weather conditions, water level, stream flow, and post-collection conditions. If all pertinent information will not fit on a label or attached tag, record information in a bound sample log book at the sampling site at the time of sample collection. Use waterproof ink to record all information (preferably with black, non-solvent-based ink). Fix sampling points by detailed description in the sampling plan, by maps, or with the aid of stakes, buoys, or landmarks in a manner that will permit their identification by other persons without reliance on memory or personal guidance. Global positioning systems (GPS) also can supply accurate sampling position data. Particularly when sample results are expected to be involved in litigation, use formal "chain-of-custody" procedures (see 1060B.2), which trace sample history from collection to final reporting.

Before collecting samples from distribution systems, flush lines with three to five pipe volumes (or until water is being drawn from the main source) to ensure that the sample is representative of the supply, taking into account the volume of pipe to be flushed and the flow velocity. If the distribution system volume is unavailable, flush with tap fully open for at least 2 to 3 min before sampling. An exception to these guidelines (i.e., collecting a first-draw sample) is when information on areas of reduced or restricted flow is desired or when samples for lead in drinking water are being collected.

Although well-pumping protocols depend on the objectives of an investigation and other factors, such as well characteristics and available equipment, a general rule is to collect samples from wells only after the well has been purged sufficiently (usually with three to ten well volumes) to ensure that the sample represents the groundwater. Purging stagnant water is critical. Sometimes it will be necessary to pump at a specified rate to achieve a characteristic drawdown, if this determines the zones from which the well is supplied; record purging rate and drawdown, if necessary. By using methods with minimal drawdown, purging volumes can be reduced significantly.

When samples are collected from a river or stream, observed results may vary with depth, stream flow, and distance from each shore. Selection of the number and distribution of sites at which samples should be collected depends on study objectives, stream characteristics, available equipment, and other factors. If equipment is available, take an integrated sample from top to bottom in the middle of the main channel of the stream or from side to

side at mid-depth. If only grab or catch samples can be collected, preferably take them at various points of equal distance across the stream; if only one sample can be collected, take it in the middle of the main channel of the stream and at mid-depth. Integrated samples are described further in 1060B.1c.

Rivers, streams, lakes, and reservoirs are subject to considerable variations from normal causes (e.g., seasonal stratification, diurnal variations, rainfall, runoff, and wind). Choose location, depth, and frequency of sampling depending on local conditions and the purpose of the investigation.

Use the following examples for general guidance. Avoid areas of excessive turbulence because of potential loss of volatile constituents and potential presence of denser-than-air toxic vapors. Avoid sampling at weirs, if possible, because such locations tend to favor retrieval of lighter-than-water immiscible compounds. Generally, collect samples beneath the surface in quiescent areas and open sampling container below surface with the mouth directed toward the current to avoid collecting surface scum unless oil and grease is a constituent of interest; then collect water at the surface. If composite samples are required, ensure that sample constituents are not lost during compositing because of improper handling of portions being composited. If samples will be analyzed for organic constituents, refrigerate composited portions. Do not composite samples for VOC analysis because some of the components will be lost through volatilization.

2. Safety Considerations

Because sample constituents may be toxic, take adequate precautions during sampling and sample handling. Toxic substances can enter through the skin and eyes and, in the case of vapors, also through the lungs. Ingestion can occur via direct contact of toxic materials with foods or by adsorption of vapors onto foods. Precautions may be limited to wearing gloves or may include coveralls, aprons, or other protective apparel. Often, the degree of protection provided by chemical protective clothing (CPC) is specific for different manufacturers and their product models¹; ensure that the clothing chosen will offer adequate protection. Always wear eye protection (e.g., safety glasses with side shields or goggles). When toxic vapors may be present, sample only in well-ventilated areas, or use an appropriate respirator or self-contained breathing apparatus. In a laboratory, open sample containers in a fume hood. Never have food in the laboratory, near samples, or near sampling locations; always wash hands thoroughly before handling food.²

Always prohibit eating, drinking, or smoking near samples, sampling locations, and in the laboratory. Keep sparks, flames, and excessive heat sources away from samples and sampling locations. If flammable compounds are suspected or known to be present and samples will be refrigerated, use only specially designed explosion-proof refrigerators.²

Collect samples safely, avoiding situations that may lead to accidents. When in doubt as to the level of safety precautions needed, consult a knowledgeable industrial hygienist or safety professional. Samples with radioactive contaminants may require other safety considerations; consult a health physicist.

Label adequately any sample known or suspected to be hazardous because of flammability, corrosivity, toxicity, oxidizing chemicals, or radioactivity, so appropriate precautions can be taken during sample handling, storage, and disposal.

1060 B. Collection of Samples

1. Types of Samples

a. Grab samples: Grab samples are single samples collected at a specific spot at a site over a short period of time (typically seconds or minutes). Thus, they represent a “snapshot” in both space and time of a sampling area. Discrete grab samples are taken at a selected location, depth, and time. Depth-integrated grab samples are collected over a predetermined part or the entire depth of a water column, at a selected location and time in a given body of water.

A sample can represent only the composition of its source at the time and place of collection. However, when a source is known to be relatively constant in composition over an extended time or over substantial distances in all directions, then the sample may represent a longer time period and/or a larger volume than the specific time and place at which it was collected. In such circumstances, a source may be represented adequately by single grab samples. Examples are protected groundwater supplies, water supplies receiving conventional treatment, some well-mixed surface waters, but rarely wastewater streams, rivers, large lakes, shorelines, estuaries, and groundwater plumes.

When a source is known to vary with time, grab samples collected at suitable intervals and analyzed separately can document the extent, frequency, and duration of these variations. Choose sampling intervals on the basis of the expected frequency of changes, which may vary from 5 min to 1 h or more. Seasonal variations in natural systems may necessitate sampling over months. When the source composition varies in space (i.e., from location to location) rather than time, collect samples from appropriate locations that will meet the objectives of the study (for example, upstream and downstream from a point source).

The same principles apply to sampling wastewater sludges, sludge banks, and muds, although these matrices are not specifically addressed in this section. Take every possible precaution to obtain a representative sample or one conforming to a sampling program.

b. Composite samples: Composite samples should provide a more representative sampling of heterogeneous matrices in which the concentration of the analytes of interest may vary over short periods of time and/or space. Composite samples can be obtained by combining portions of multiple grab samples or by using specially designed automatic sampling devices. Sequential (time) composite samples are collected by using continuous, constant sample pumping or by mixing equal water volumes collected at regular time intervals. Flow-proportional composites are collected by continuous pumping at a rate proportional to the flow, by mixing equal volumes of water collected at time intervals that are inversely proportional to the volume of flow, or by mixing volumes of water proportional to the flow collected during or at regular time intervals.

Advantages of composite samples include reduced costs of analyzing a large number of samples, more representative samples of heterogeneous matrices, and larger sample sizes when amounts of test samples are limited. Disadvantages of composite samples include loss of analyte relationships in individual samples, potential dilution of analytes below detection levels, increased potential analytical interferences, and increased possibility of analyte interactions. In addition, use of composite samples may reduce the number of samples analyzed below the required statistical need for specified data quality objectives or project-specific objectives.

Do not use composite samples with components or characteristics subject to significant and unavoidable changes during storage. Analyze individual samples as soon as possible after collection and preferably at the sampling point. Examples are dissolved gases, residual chlorine, soluble sulfide, temperature, and pH. Changes in components, such as dissolved oxygen or carbon dioxide, pH, or temperature, may produce secondary changes in certain inorganic constituents, such as iron, manganese, alkalinity, or hardness. Some organic analytes also may be changed by changes in the foregoing components. Use time-composite samples only for determining components that can be demonstrated to remain unchanged under the conditions of sample collection, preservation, and storage.

Collect individual portions in a wide-mouth bottle every hour (in some cases, every half hour or even every 5 min) and mix at the end of the sampling period or combine in a single bottle as collected. If preservatives are used, add them to the sample bottle initially so all portions of the composite are preserved as soon as collected.

Automatic sampling devices are available; however, do not use them unless the sample is preserved as described below. Composite samplers running for extended periods (weeks to months) should undergo routine cleaning of containers and sample lines to minimize sample growth and deposits.

c. Integrated (discharge-weighted) samples: For certain purposes, the information needed is best provided by analyzing mixtures of grab samples collected from different points simultaneously, or as nearly so as possible, using discharge-weighted methods [e.g., equal-width increment (EWI) or equal discharge-increment (EDI) procedures and equipment]. An example of the need for integrated sampling occurs in a river or stream that varies in composition across its width and depth. To evaluate average composition or total loading, use a mixture of samples representing various points in the cross-section, in proportion to their relative flows. The need for integrated samples also may exist if combined treatment is proposed for several separate wastewater streams, the interaction of which may have a significant effect on treatability or even on composition. Mathematical prediction of the interactions among chemical components may

be inaccurate or impossible, and testing a suitable integrated sample may provide more useful information.

Both lakes and reservoirs show spatial variations of composition (depth and horizontal location). However, there are conditions under which neither total nor average results are especially useful, but local variations are more important. In such cases, examine samples separately (i.e., do not integrate them).

Preparation of integrated samples usually requires equipment designed to collect a sample water uniformly across the depth profile. Knowledge of the volume, movement, and composition of the various parts of the water being sampled usually is required. Collecting integrated samples is a complicated and specialized process that must be described adequately in a sampling plan.

2. Chain-of-Custody Procedures

Properly designed and executed chain-of-custody forms will ensure sample integrity from collection to data reporting. This includes the ability to trace possession and handling of the sample from the time of collection through analysis and final disposition. This process is referred to as *chain of custody* and is required to demonstrate sample control when the data are to be used for regulation or litigation. Where litigation is not involved, chain-of-custody procedures are useful for routine control of samples.

A sample is considered to be under a person's custody if it is in the individual's physical possession, in the individual's sight, secured and tamper-proofed by that individual, or secured in an area restricted to authorized personnel. The following procedures summarize the major aspects of chain of custody. More detailed discussions are available.^{1,2}

a. Sample labels (including bar-code labels): Use labels to prevent sample misidentification. Gummed paper labels or tags generally are adequate. Include at least the following information: a unique sample number, sample type, name of collector, date and time of collection, place of collection, and sample preservative. Also include date and time of preservation for comparison to date and time of collection. Affix tags or self-adhesive labels to sample containers before, or at the time of, sample collection.

b. Sample seals: Use sample seals to detect unauthorized tampering with samples up to the time of analysis. Use self-adhesive paper seals that include at least the following information: sample number (identical with number on sample label), collector's name, and date and time of sampling. Plastic shrink seals also may be used.

Attach seal so that it must be broken to open the sample container or the sample shipping container (e.g., a cooler). Affix seal to container before sample leaves custody of sampling personnel.

c. Field log book: Record all information pertinent to a field survey or sampling in a bound log book. As a minimum, include the following in the log book: purpose of sampling; location of sampling point; name and address of field contact; producer of material being sampled and address (if different from location); type of sample; and method, date, and time of preservation. If the sample is wastewater, identify process producing waste stream. Also provide suspected sample composition, including concentrations; number and volume of sample(s) taken; description of sampling point and sampling method; date and time of collection; collector's sample identification number(s); sample distribution and how transported; references (e.g., maps or photographs of the sampling site); field

observations and measurements; and signatures of personnel responsible for observations. Because sampling situations vary widely, it is essential to record sufficient information so one could reconstruct the sampling event without reliance on the collector's memory. Protect log book and keep it in a safe place.

d. Chain-of-custody record: Fill out a chain-of-custody record to accompany each sample or group of samples. The record includes the following information: sample number; signature of collector; date, time, and address of collection; sample type; sample preservation requirements; signatures of persons involved in the chain of possession; and inclusive dates and times of possession.

e. Sample analysis request sheet: The sample analysis request sheet accompanies samples to the laboratory. The collector completes the field portion of the form, which includes most of the pertinent information noted in the log book. The laboratory portion of the form is to be completed by laboratory personnel and includes: name of person receiving the sample, laboratory sample number, date of sample receipt, condition of each sample (if it is cold or warm, whether the container is full or not, color, if more than one phase is present, etc.), and determinations to be performed.

f. Sample delivery to the laboratory: Deliver sample(s) to laboratory as soon as practicable after collection, typically within 2 d. If shorter sample holding times are required, make special arrangements to ensure timely delivery to the laboratory. If samples are shipped by a commercial carrier, include the waybill number in the sample custody documentation. Ensure that samples are accompanied by a completed chain-of-custody record and a sample analysis request sheet. Deliver sample to sample custodian.

g. Receipt and logging of sample: In the laboratory, the sample custodian inspects the condition and seal of the sample and reconciles label information and seal against the chain-of-custody record before the sample is accepted for analysis. After acceptance, the custodian assigns a laboratory number, logs sample in the laboratory log book and/or computerized laboratory information management system, and stores it in a secured storage room or cabinet or refrigerator at the specified temperature until it is assigned to an analyst.

h. Assignment of sample for analysis: The laboratory supervisor usually assigns the sample for analysis. Once the sample is in the laboratory, the supervisor or analyst is responsible for its care and custody.

i. Disposal: Hold samples for the prescribed amount of time for the project or until the data have been reviewed and accepted. Document the disposition of samples. Ensure that disposal is in accordance with local-, state-, and U.S. EPA-approved methods.

3. Sampling Methods

a. Manual sampling: Manual sampling involves minimal equipment but may be unduly costly and time-consuming for routine or large-scale sampling programs. It requires trained field technicians and is often necessary for regulatory and research investigations for which critical appraisal of field conditions and complex sample-collection techniques are essential. Manually collect certain samples, such as waters containing oil and grease.

b. Automatic sampling: Automatic samplers can eliminate human errors in manual sampling, can reduce labor costs, may

provide the means for more frequent sampling,³ and are increasingly used. Be sure that the automatic sampler does not contaminate the sample. For example, plastic components may be incompatible with certain organic compounds that are soluble in the plastic parts or that can be contaminated (e.g., from phthalate esters) by contact with them. If sample constituents are generally known, contact the manufacturer of an automatic sampler regarding potential incompatibility of plastic components.

Program an automatic sampler in accordance with sampling needs. Carefully match pump speeds and tubing sizes to the type of sample to be taken.

c. Sorbent sampling: Use of solid sorbents, particularly membrane-type disks, is becoming more frequent. These methods offer rapid, inexpensive sampling if the analytes of interest can be adsorbed and desorbed efficiently and the water matrix is free of particulates that plug the sorbent.

4. Sample Containers

The type of sample container used is of utmost importance. Test sample containers and document that they are free of analytes of interest, especially when sampling and analyzing for very low analyte levels. Containers typically are made of plastic or glass, but one material may be preferred over the other. For example, silica, sodium, and boron may be leached from soft glass, but not plastic, and trace levels of some pesticides and metals may sorb onto the walls of glass containers.⁴ Thus, hard glass containers* are preferred. For samples containing organic compounds, do not use plastic containers except those made of fluorinated polymers, such as polytetrafluoroethylene (PTFE).³

Some sample analytes may dissolve (be absorbed) into the walls of plastic containers; similarly, contaminants from plastic containers may leach into samples. Avoid plastics wherever possible because of potential contamination from phthalate esters. Container failure due to breakdown of the plastic is possible. Therefore, use glass containers for all organics analyses, such as volatile organics, semivolatile organics, pesticides, PCBs, and oil and grease. Some analytes (e.g., bromine-containing compounds and some pesticides, and polynuclear aromatic compounds) are light-sensitive; collect them in amber-colored glass containers to minimize photodegradation. Container caps, typically plastic, also can be a problem. Do not use caps with paper liners. Use foil or PTFE liners but be aware that metal liners can contaminate samples collected for metals analysis and they may also react with the sample if it is acidic or alkaline. Serum vials with PTFE-lined rubber or plastic septa are useful.

In rare situations, it may be necessary to use sample containers not specifically prepared for use, or otherwise unsuitable for the particular situation; thoroughly document these deviations. Documentation should include type and source of container, and the preparation technique (e.g., acid washed with reagent water rinse). For QA purposes, the inclusion of a bottle blank may be necessary.

5. Number of Samples

Because of variability from analytical and sampling procedures (i.e., population variability), a single sample is insufficient to reach any reasonable desired level of confidence. If an overall standard

Figure 1060:1. Approximate number of samples required in estimating a mean concentration. SOURCE: Methods for the Examination of Waters and Associated Materials: General Principles of Sampling and Accuracy of Results. 1980. Her Majesty's Stationery Off., London, England.

deviation (i.e., the standard deviation of combined sampling and analysis) is known, the required number of samples for a mobile matrix, such as water, may be estimated as follows:⁴

$$N \geq \left(\frac{ts}{U} \right)^2$$

where:

- N = number of samples,
- t = Student's t statistic for a given confidence level,
- s = overall standard deviation, and
- U = acceptable level of uncertainty.

To assist in calculations, use curves such as those in Figure 1060:1. As an example, if s is 0.5 mg/L, U is ± 0.2 mg/L, and a 95% confidence level is desired, approximately 25 to 30 samples must be taken.

The above equation assumes that total error (population variability) is known. Total variability consists of all sources of variability, including the distribution of the analytes of interest within the sampling site; collection, preservation, preparation, and analysis of samples; and data handling and reporting. In simpler terms, error (variability) can be divided into sampling and analysis components. Sampling error due to population variability (including heterogeneous distribution of analytes in the environmental matrix) usually is much larger than analytical error components. Unfortunately, sampling error usually is not

* Pyrex, or equivalent.

available and the analyst is left with only the published error of the measurement system (typically obtained by using a reagent water matrix under the best analytical conditions).

More accurate equations are available.⁵ These are based on the Z distribution for determining the number of samples needed to estimate a mean concentration when variability is estimated in absolute terms using the standard deviation. The coefficient of variation [relative standard deviation (RSD)] is used when variability is estimated in relative terms.

The number of random samples to be collected at a site can be influenced partly by the method that will be used. The values for standard deviation (SD) or RSD may be obtained from each of the methods or in the literature.⁶ However, calculations of estimated numbers of samples needed based only on this information will result in underestimated numbers of samples because only the analytical variances are considered, and the typically larger variances from the sampling operations are not included. Preferably, determine and use SDs or RSDs from overall sampling and analysis operations.

For estimates of numbers of samples needed for systematic sampling (e.g., drilling wells for sampling groundwater or for systematically sampling large water bodies, such as lakes), equations are available⁷ that relate number of samples to shape of grid, area covered, and space between nodes of grid. The grid spacing is a complex calculation that depends on the size and shape of any contaminated spot (such as a groundwater plume) to be identified, in addition to the geometric shape of the sampling grid.

See individual methods for types and numbers of quality assurance (QA) and quality control (QC) samples [e.g., for normal-level (procedural) or low-level (contamination) bias or for precision] involving sampling or laboratory analysis (either overall or individually). Estimates of numbers of QC samples needed to achieve specified confidence levels also can be calculated. Rates of false positives (Type I error) and false negatives (Type II error) are useful parameters for estimating required numbers of QC samples. A false positive is the incorrect conclusion that an analyte is present when it is absent. A false negative is the incorrect conclusion that an analyte is absent when it is present. If the frequency of false positives or false negatives desired to be detected is <10%, then

$$n = \frac{\ln \alpha}{\ln (1 - Y)}$$

where:

α = (1 - desired confidence level), and
 Y = frequency to detect (<10%).

If the frequency that is desirable to detect is >10%, iterative solution of a binomial equation is necessary.^{5,8}

Equations are available as a computer program[†] for computing sample number by the Z distribution, for estimating samples needed in systematic sampling, and for estimating required number of QC samples.

6. Sample Volumes

Collect a 1-L sample for most physical and chemical analyses. For certain determinations, larger samples may be necessary. Table 1060:I lists volumes ordinarily required for analyses, but it is strongly recommended that the laboratory that will conduct the analyses also be consulted to verify the analytical needs of sampling procedures as they pertain to the goals and data quality objective of an investigation.

Do not use samples from the same container for multiple testing requirements (e.g., organic, inorganic, radiological, bacteriological, and microscopic examinations) because methods of collecting and handling are different for each type of test. Always collect enough sample volume in the appropriate container in order to comply with sample handling, storage, and preservation requirements.

COLLECTION AND PRESERVATION OF SAMPLES (1060)/Collection of Samples

TABLE 1060:I. SUMMARY OF SPECIAL SAMPLING AND HANDLING REQUIREMENTS*

Determination	Container†	Minimum Sample Size mL	Sample Type‡	Preservation§	Maximum Storage Recommended	Regulatory
Acidity	P, G(B), FP	100	g	Cool, $\leq 6^{\circ}\text{C}$	24 h	14 d
Alkalinity	P, G, FP	200	g	Cool, $\leq 6^{\circ}\text{C}$	24 h	14 d
BOD	P, G, FP	1000	g, c	Cool, $\leq 6^{\circ}\text{C}$	6 h	48 h
Boron	F, P (PTFE) or quartz	1000	g, c	HNO_3 to $\text{pH} < 2$	28 d	6 months
Bromide	P, G, FP	100	g, c	None required	28 d	28 d
Carbon, organic, total	G(B), P, FP	100	g, c	Analyze immediately, or cool $\leq 6^{\circ}\text{C}$ and add HCl , H_3PO_4 , or H_2SO_4 to pH	7 d	28 d
Carbon dioxide	P, G	100	g	Analyze immediately	0.25 h	N.S.
COD	P, G, FP	100	g, c	Analyze as soon as possible, or add H_2SO_4 to $\text{pH} < 2$; Cool, $\leq 6^{\circ}\text{C}$	7 d	28 d
Chloride	P, G, FP	50	g, c	None required	N.S.	28 d
Chlorine, total, residual	P, G	500	g	Analyze immediately	0.25 h	0.25 h
Chlorine dioxide	P, G	500	g	Analyze immediately	0.25 h	N.S.
Chlorophyll	P, G	500	g	Unfiltered, dark, $\leq 6^{\circ}\text{C}$ Filtered, dark, -20°C (Do not store in frost-free freezer)	24–48 h 28 d	N.S.
Color	P, G, FP	500	g, c	Cool, $\leq 6^{\circ}\text{C}$	24 h	48 h
Specific conductance	P, G, FP	500	g, c	Cool, $\leq 6^{\circ}\text{C}$	28 d	28 d
Cyanide						
Total	P, G, FP	1000	g, c	Analyze within 15 min. Add NaOH to $\text{pH} > 12$ if sample is to be stored, Cool, $\leq 6^{\circ}\text{C}$, in dark. Add thiosulfate if residual chlorine present	24 h	14 d; 24 h if sulfide present
Amenable to chlorination	P, G, FP	1000	g, c	Remove residual chlorine with thiosulfate and cool $\leq 6^{\circ}\text{C}$	stat	14 d; 24 h if sulfide present
Fluoride	P	100	g, c	None required	28 d	28 d
Hardness	P, G, FP	100	g, c	Add HNO_3 or H_2SO_4 to $\text{pH} < 2$	6 months	6 months
Iodine	P, G	500	g	Analyze immediately	0.25 h	N.S.
Metals	P(A), G(A), FP (A)	1000	g, c	For dissolved metals filter immediately, add HNO_3 to $\text{pH} < 2$	6 months	6 months
Chromium VI	P(A), G(A), FP (A)	250	g	Cool, $\leq 6^{\circ}\text{C}$, pH 9.3–9.7, ammonium sulfate buffer preservative as specified in method 3500-Cr to extend to 28 d HT	28 d	28 d
Copper by colorimetry	—*	—	g, c	—	—	—
Mercury	P(A), G(A), FP(A)	500	g, c	Add HNO_3 to $\text{pH} < 2$, Cool $\leq 6^{\circ}\text{C}$	28 d	28 d
Nitrogen						
Ammonia	P, G, FP	500	g, c	Analyze as soon as possible or add H_2SO_4 to $\text{pH} < 2$, Cool, $\leq 6^{\circ}\text{C}$	7 d	28 d
Nitrate	P, G, FP	100	g, c	Analyze as soon as possible; Cool, $\leq 6^{\circ}\text{C}$	48 h	48 h (14 d for chlorinated samples)
Nitrate + nitrite	P, G, FP	200	g, c	Add H_2SO_4 to $\text{pH} < 2$, Cool, $\leq 6^{\circ}\text{C}$	1–2 d	28 d
Nitrite	P, G, FP	100	g, c	Analyze as soon as possible; Cool, $\leq 6^{\circ}\text{C}$	none	48 h
Organic, Kjeldahl	P, G, FP	500	g, c	Cool, $\leq 6^{\circ}\text{C}$, add H_2SO_4 to $\text{pH} < 2$	7 d	28 d
Odor	G	500	g	Analyze as soon as possible; Cool $\leq 6^{\circ}\text{C}$	6 h	24 h (EPA Manual drinking water)
Oil and grease	G, wide-mouth calibrated	1000	g	Add HCl or H_2SO_4 to $\text{pH} < 2$, Cool, $\leq 6^{\circ}\text{C}$	28 d	28 d

COLLECTION AND PRESERVATION OF SAMPLES (1060)/Collection of Samples

TABLE 1060:I. CONT.

Determination	Container†	Minimum Sample Size mL	Sample Type‡	Preservation§	Maximum Storage Recommended	Regulatory
Organic Compounds						
MBAS	P, G, FP	250	g, c	Cool, $\leq 6^{\circ}\text{C}$	48 h	48 h as per CFR 136
Pesticides*	G(S), PTFE-lined cap	1000	g, c	Cool, $\leq 6^{\circ}\text{C}$, add 1000 mg ascorbic acid/L if residual chlorine present (0.008% sodium thiosulfate in CFR 136)	7 d	7 d until extraction; 40 d after extraction
Phenols	P, G, PTFE-lined cap	500	g, c	Cool, $\leq 6^{\circ}\text{C}$, add H_2SO_4 to $\text{pH} < 2$	*	28 d until extraction, 2 d after extraction
Purgeables* by purge and trap	G, PTFE-lined cap	2×40	g	Cool, $\leq 6^{\circ}\text{C}$; add HCl to $\text{pH} < 2$; add 1000 mg ascorbic acid/L if residual chlorine present (0.008% sodium thiosulfate in CFR 136)	7 d	14 d
Base/neutrals & acids	G(S) amber	1000	g, c	Cool, $\leq 6^{\circ}\text{C}$, 0.008% sodium thiosulfate in CFR 136 if chlorine is present	7 d	7 d until extraction; 40 d after extraction
Oxygen, dissolved	G, BOD bottle	300	g	Analyze immediately	0.25 h	0.25 h
Electrode				Titration may be delayed after acidification	8 h	8 h
Winkler						
Ozone	G	1000	g	Analyze immediately	0.25 h	N.S.
pH	P, G	50	g	Analyze immediately	0.25 h	0.25 h
Phosphate	G(A)	100	g	For dissolved phosphate filter immediately; Cool, $\leq 6^{\circ}\text{C}$	48 h	48 h as per EPA manual for DW
Phosphorus, total	P, G, FP	100	g, c	Add H_2SO_4 to $\text{pH} < 2$ and cool, $\leq 6^{\circ}\text{C}$	28 d	28 d
Salinity	G, wax seal	240	g	Analyze immediately or use wax seal	6 months	N.S.
Silica	F, P (PTFE) or quartz	200	g, c	Cool, $\leq 6^{\circ}\text{C}$, do not freeze	28 d	28 d
Sludge digester gas	G, gas bottle	—	g	—	N.S.	
Solids ⁹	P, G	200	g, c	Cool, $\leq 6^{\circ}\text{C}$	7 d	2–7 d; see cited reference
Sulfate	P, G, FP	100	g, c	Cool, $\leq 6^{\circ}\text{C}$	28 d	28 d
Sulfide	P, G, FP	100	g, c	Cool, $\leq 6^{\circ}\text{C}$; add 4 drops 2N zinc acetate/100 mL; add NaOH to $\text{pH} > 9$	28 d	7 d
Temperature	P, G, FP	—	g	Analyze immediately	0.25 h	0.25 h
Turbidity	P, G, FP	100	g, c	Analyze same day; store in dark up to 24 h, Cool, $\leq 6^{\circ}\text{C}$	24 h	48 h

* For determinations not listed, use glass or plastic containers; preferably refrigerate during storage and analyze as soon as possible.

† P = plastic (polyethylene or equivalent); G = glass; G(A) or P(A) = rinsed with 1 + 1 HNO_3 ; G(B) = glass, borosilicate; G(S) = glass, rinsed with organic solvents or baked; FP = fluoropolymer [polytetrafluoroethylene (PTFE, Teflon) or other fluoropolymer].

‡ g = grab; c = composite.

§ Cool = storage at, $> 0^{\circ}\text{C}$, $\leq 6^{\circ}\text{C}$ (above freezing point of water); in the dark; analyze immediately = analyze usually within 15 min of sample collection.

|| See citation¹⁰ for possible differences regarding container and preservation requirements. N.S. = not stated in cited reference; stat = no storage allowed; analyze immediately (within 15 min).

Some drinking water (DW) and treated wastewater (WW) matrices may be subject to positive interference as a result of preservation. If such interference is demonstrable, samples should be analyzed as soon as possible without preservation. Do not hold for more than 15 min without demonstrating that cyanide (CN) is stable for longer periods in a specific matrix.

NOTE: This table is intended for guidance only. If there is a discrepancy between this table and the method, the information in the current method takes precedence. If performing the method for compliance purposes, be aware that alternative preservation and holding-time requirements may exist. If so, the regulatory requirements should be used.

1060 C. Sample Storage and Preservation

Complete and unequivocal preservation of samples, whether domestic wastewater, industrial wastes, or natural waters, is a practical impossibility because complete stability for every constituent never can be achieved. At best, preservation techniques only retard chemical and biological changes that inevitably continue after sample collection.

1. Sample Storage before Analysis

a. Nature of sample changes: Some determinations are more affected by sample storage than others. Certain cations are subject to loss by adsorption to, or ion exchange with, the walls of glass containers. These include aluminum, cadmium, chromium, copper, iron, lead, manganese, silver, and zinc, which are best collected in a separate clean bottle and acidified with nitric acid to a pH <2.0 to minimize precipitation and adsorption on container walls. Also, some organics may be subject to loss by adsorption to the walls of glass containers.

Temperature changes quickly; pH may change significantly in a matter of minutes; dissolved gases (oxygen, carbon dioxide) may be lost. Because changes in such basic water quality properties may occur so quickly, determine temperature, reduction-oxidation potential, and dissolved gases *in situ* and pH, specific conductance, turbidity, and alkalinity immediately after sample collection. Many organic compounds are sensitive to changes in pH and/or temperature resulting in reduced concentrations during storage.

Changes in the pH-alkalinity-carbon dioxide balance may cause calcium carbonate to precipitate, decreasing the values for calcium and total hardness.

Iron and manganese are readily soluble in their lower oxidation states but relatively insoluble in their higher oxidation states; therefore, these cations may precipitate or they may dissolve from a sediment, depending on the redox potential of the sample. Microbiological activity may affect the nitrate-nitrite-ammonia content, phenol or BOD concentration, or the reduction of sulfate to sulfide. Residual chlorine is reduced to chloride. Sulfide, sulfite, ferrous iron, iodide, and cyanide may be lost through oxidation. Color, odor, and turbidity may increase, decrease, or change in quality. Sodium, silica, and boron may be leached from the glass container. Hexavalent chromium may be reduced to trivalent chromium.

The biological activity in a sample may change the oxidation state of some constituents. Soluble constituents may be converted to organically bound materials in cell structures, or cell lysis may result in release of cellular material into solution. The well-known nitrogen and phosphorus cycles are examples of biological influences on sample composition.

Zero headspace is important in preservation of samples with volatile organic compounds and radon. Avoid loss of volatile materials by collecting sample in a completely filled container. Achieve this by carefully filling the bottle so top of meniscus is above the top of the bottle rim. It is important to avoid spillage or air entrapment if preservatives, such as HCl or ascorbic acid, have already been added to the bottle. After capping or sealing bottle, check for air bubbles by inverting and gently tapping it; if one or more air bubbles are observed then, if practical, discard

the sample and repeat refilling bottle with new sample until no air bubbles are observed (this cannot be done if bottle contained preservatives before it was filled).

Serum vials with septum caps are particularly useful in that a sample portion for analysis can be taken through the cap by using a syringe,¹ although the effect of pressure reduction in the headspace must be considered. Pulling a sample into a syringe under vacuum can result in low bias data for volatile compounds and the resulting headspace precludes taking further subsamples.

b. Time interval between collection and analysis: In general, the shorter the time that elapses between collection of a sample and its analysis, the more reliable will be the analytical results. For certain constituents and physical values, immediate analysis in the field is required. For composited samples, it is common practice to use the time at the end of composite collection as the sample-collection time.

Check with the analyzing laboratory to determine how much elapsed time may be allowed between sample collection and analysis; this depends on the character of the sample and the stability of the target analytes under storage conditions. Many regulatory methods limit the elapsed time between sample collection and analysis (see Table 1060:I). Changes caused by growth of microorganisms are greatly retarded by keeping the sample at a low temperature (<6°C but above freezing). When the interval between sample collection and analysis is long enough to produce changes in either the concentration or physical state of the constituent to be measured, follow the preservation practices given in Table 1060:I. Record time elapsed between sampling and analysis, and which preservative, if any, was added.

2. Preservation Techniques

To minimize the potential for volatilization or biodegradation between sampling and analysis, keep samples as cool as possible without freezing. Preferably pack samples in crushed or cubed ice or commercial ice substitutes before shipment. Avoid using dry ice because it will freeze samples and may cause glass containers to break. Dry ice also may effect a pH change in samples. Keep composite samples cool with ice or a refrigeration system set at ≤6°C during compositing. Analyze samples as quickly as possible on arrival at the laboratory. If immediate analysis is not possible, preferably store at ≤6°C.¹

No single method of preservation is entirely satisfactory; choose the preservative with due regard to the determinations to be made. Use chemical preservatives only when they do not interfere with the analysis being made. When they are used, add them to the sample bottle initially so all sample portions are preserved as soon as collected. Because a preservation method for one determination may interfere with another one, samples for multiple determinations may need to be split and preserved separately. All preservation methods may be inadequate when applied to suspended matter. Do not use formaldehyde as a preservative for samples collected for chemical analysis because it affects many of the target analytes.

Preservation methods are relatively limited and are intended generally to retard biological action, retard hydrolysis of chemical compounds and complexes, and reduce volatility of constituents.

Preservation methods are limited to pH control, chemical addition, the use of amber and opaque bottles, refrigeration, filtration, and freezing. Table 1060:I lists preservation methods by constituent. See Section 7010B for sample collection and preservation requirements for radionuclides.

The foregoing discussion is by no means exhaustive and comprehensive. Clearly, it is impossible to prescribe absolute rules for preventing all possible changes. Additional advice will be found in the discussions under individual determinations, but to a large degree, the dependability of an analytical determination rests on the experience and good judgment of the person

collecting the sample. Numbers of samples required for confidence levels in data quality objectives, however, rely on statistical equations, such as those discussed earlier.

Date: June 1, 2023

*Subject: Chlorine System Automation Evaluation, TM -19
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) evaluates the opportunities for automation based on flow and total residual chlorine of the chlorine disinfection system at the Oakwood Combined Sewer Overflow (CSO) Retention and Treatment Basin (RTB) (Oakwood) and Leib Screening and Disinfection Facility (SDF) (Leib) as the objective of the task OKW-DIS-2 and LEIB-DIS-2. This TM is focused on determining the chlorine demand using instantaneously available data which will allow for more optimized system that uses less sodium hypochlorite to confidently meet a desired effluent quality. This TM describes the disinfection system control, online analyzers and sampling system at Oakwood and Leib.

Existing Disinfection Control System

Disinfection system control is implemented manually at local control panels and remotely through the Emerson Ovation Distributed Control System (DCS). The Oakwood facility presently utilizes the Ovation DCS platform, while the Leib facility will be upgraded to the Ovation DCS platform under CIP 260617 prior to this project being commissioned. Presently, the Leib facility utilizes a Rockwell control system platform that provides local monitoring and control within the facility at the operator workstations and remote monitoring from the PCC. Once the control system platform is upgraded at Leib, remote control capability will be available. At Oakwood, each storm pump has a dedicated sodium hypochlorite feed pump with three modes of controls: manual from the local control panel, and two automatic modes. In automatic mode, programming within Ovation Control System can be used to vary the feed rate in the two ways, the sodium hypochlorite dose multiplied by Contact Time (also called CT method) or Total Suspended Solids (TSS) method. Operators at Oakwood indicated that presently the chemical feed pumps are operated manually with the manual

total residual chlorine (TRC) check as guide to make changes to the sodium hypochlorite feed rates. As the storm flow measurement is questionable, operators do not rely on the sodium hypochlorite feed rate determined by the control system and tend to use high sodium hypochlorite feed rates to make sure the required disinfection is being achieved. At Leib, disinfection is performed using a CT method.

Existing Sampling System

At both facilities, influent sampling is not needed for facility operation, so no sampling pumps are used. At Leib, the sampling pumps in the Influent Channel and Effluent Channel are not in use. Thus, the samplers for the untreated flow from the Influent Channel and the screened and disinfected flow in the Effluent Channel were removed. The Outfall Sampling unit was turned off because there is no potable water source for standby operation. The effluent sampling at both facilities are used to monitor effluent water quality as needed for the National Pollutant Discharge Elimination System (NPDES) permit compliance.

Disinfection Control Functionality

The four modes of controlling the chlorination system will be: Manual Control, Flow Paced, Integrated Contact Time (ICT) Dose Paced with TRC Analyzers, and Machine Learning (ML) Dosing Model.

Manual Control:

In this mode the sodium hypochlorite feed system will be started, stopped, and controlled manually from either local control panel or Ovation Control System. Operators will use the selected ICT value, the sodium hypochlorite concentration, and inputs from storm flow meter(s) to determine the sodium hypochlorite feed rate. If the online TRC analyzer sampling system is implemented, it will provide a tool to manually adjust the feed rate. This mode will have lowest data requirement and no complex instrumentation. This control will require the use of higher safety factors in sodium hypochlorite feed rates to account for the uncertainty to achieve required disinfection and increasing sodium hypochlorite usage and costs and potential corrosion due to high sodium hypochlorite dose and off gassing of chlorine at the downstream processes.

Flow Paced:

In this mode the chemical feed system will be started, stopped, and controlled based on the flow inputs from the storm flow meter. Operators will select the chemical dose based on the selected ICT value and the stored sodium hypochlorite trade percent by weight concentration. Flow paced control will have less amount of automation as it is only related to the influent flow and chemical feed rate. It will lower the safety factor and will result in chemical savings compared to the manual control mode.

ICT Dose Paced with TRC Analyzers:

ICT dose pacing with TRC analyzers is similar to flow paced using ICT dose but adds a continuous feedback of TRC concentration data to optimize chemical dosage. The initial sodium hypochlorite

dose during an event will be based on the ICT dose developed as part of this project, thereafter the dose will be continuously adjusted to maintain a selected effluent TRC. This control mode will provide data driven high confidence in chemical dose optimization and minimization in dose safety factor resulting in lower sodium hypochlorite usage reduced chemical costs and potential corrosion due to high sodium hypochlorite dose and off gassing of chlorine at the downstream processes corrosion. It will have less manual operation and staff involvement. The continuous data collection by analyzers will incrementally improve the dosing algorithm. This control mode will involve automation and higher capital investment in analyzers and SCADA integration.

Machine Learning Dosing Model:

Machine Learning is a branch of computer science field dedicated to developing and implementing algorithms that allow computers to learn without being explicitly programmed to provide predictions and pattern recognition. Influent water quality is correlated to chlorine demand, and upstream environmental and system characteristics drive influent water quality. ML dosing models use predictive algorithms to characterize the relationship between the CSO flow, water quality parameters, and chlorine demand. This subsection will provide information on the basic concepts, chlorine demand prediction model approach, ML workflow, and project work plan. There are two groups of ML models, supervised learning and unsupervised learning.

The ML model predicts changes in the present chlorine demand using the historical chlorine dose collected during a year of operation, TRC, and upstream water characteristics such as organic load, precipitation data, radar imagery, flow information, and date-time information, gathered through the Ovation integration from water quality analyzers at the influent of each facility, along with weather information from outside sources. ML workflow will include data identification and collection, data collection design, data processing, exploratory data analysis, model development, model deployment, and computing. The project work plan will be evaluated during the design, construction, and development phases. A well-trained model would provide minimized dose safety factors lowering chemical costs and corrosion. Continuous data collected by analyzers incrementally improve the dosing algorithm and potential to optimize the disinfection process further and reduce operator work. This model will need the highest capital involvement in analyzers and SCADA integration and will depend on the operation and maintenance of analyzers.

The recommendation is to train the ML model to optimize disinfectant usage by learning from historical system performance after 1 year of operation post upgrades. The investigation will identify which correlations between data from influent water quality online analyzers and disinfection performance to determine if the chlorine dose can be optimized in a broader range of conditions. If more data is collected after the first year of operation, a ML model could be continuously retrained to improve its accuracy over time. The recommendation is to have a discussion with the Great Lakes Water Authority (GLWA) about the group of staff to be involved in the ML aspect of the project, and the associated testing and research and development group could be more suitable for this task.

Analyzer Type

The recommendation is to provide on-line TRC analyzers to measure the real-time TRC concentrations at both facilities. The analyzers will provide inputs to the Ovation DCS for adjustment of the chemical feed rates, viewing of real-time data from the Ovation operator workstations, historical data collection from the Ovation historian, and provides the data necessary for the ML dosing model. Use of online analyzers in intermittent flow applications, like CSO treatment facilities is a challenge. However, providing a continuous flow stream for keeping the sensors wet and providing routine maintenance help mitigate these challenges. GLWA presently utilizes on-line TRC analyzers on an intermittent flow stream at the Water Resource Recovery Facility (WRRF) to monitor the TRC in the Rouge River Outfall (RRO) that is placed into service during wet weather events. The colorimetric TRC analyzer is recommended based on its advantages over amperometric technology. During Workshop No. 3 (TM Set 2A) on May 12, 2023 it was determined to use the colorimetric TRC analyzer manufactured by the SWAN Analytical Instruments.

Sampling System Functionality

The automatic/online sampling is required to implement on-line analyzers to measure parameters in real time. The sampling system functionality recommendations are summarized in the **Table ES-1** for Oakwood and **Table ES-2** for Leib.

Table ES-1 Recommended Sampling System at Oakwood

Sampling System	Sample Location	Sample Collection System	Sampler /Analyzer Location	Parameters	Need
Influent Sampling System	Influent East and West Wet Wells	- Replace existing influent sample pumps with similar type - Reuse existing sampling piping	Influent Sampling Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	At Screen Inlet Chamber upstream of screens	- Three sample locations between pump discharge standpipes and screen inlets. - Three submersible sample pumps located in Screen Inlet Chamber	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System	One sample location at each CSO basin before effluent weir	One sample pump at each CSO Basin	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Effluent channel	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

Table ES-2 Recommended Sampling System at Leib

Sampling System	Sample Location	Sample Collection System	Sampler Location	Parameters	Need
Influent Sampling System	Influent Channel	- Replace existing influent sample pump with similar type - Reuse existing sampling piping	Sample Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	Effluent Channel right after the end of facility	- One sample location. - Two sample pumps (one duty / one standby) located in the Effluent Channel	Sample Room in the Control Building	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System ¹	Outfall (if online analyzer needed)	Outfall (if online analyzer selected)	Outfall Sample Pit (if online analyzer selected)	TRC	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Continue using existing location	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

Note: 1. Online TRC analyzer not proposed for the Chlorine Decay Sampling due to the challenges with the remote location.

1.0 Introduction and Purpose

As part of the CSO Facility Improvements project the GLWA is making disinfection system improvements to the Oakwood Retention and Treatment Basin and Leib Screening and Disinfection Facility. Those improvements include upgrading the sodium hypochlorite storage, and feed systems at both facilities to improve their reliability, flexibility, simplicity, ease of operation and maintenance, and robustness, all with an eye toward doing so in a way that optimizes the amount of sodium hypochlorite utilized to meet the discharge permit requirements and TRC goals. The objective of the task OKW-DIS-2 and LEIB-DIS-2 is to address GLWA's goal of optimizing and automating the chlorine disinfection system. The task is achieving optimization with four steps approach and summarizing the work performed under each step in the respective technical memorandums (TMs).

- Review of historical data and supplemental sampling (refer to TMs-20 and 17 respectively)
- Assess hydraulic efficiency of chemical mixing and downstream contact volume (refer to TM – 20 for computational fluid dynamic (CFD) analysis (refer to TM-20 Appendix B) and contact volume)
- Optimizing chlorination process by performing dose response testing and determining the appropriate integrated contact time (ICT) (refer to TM-18 Chlorine Dose Response Results and ICT Model)
- Evaluate opportunities for automation (presented in this TM)

The chlorine dose response tests provide initial estimates of chlorine demand and decay from the sampled storm events. This TM is focused on determining the chlorine demand using on-line analyzers or readily available real-time data which will allow for more optimized system that uses less chemicals to confidently meet a desired effluent quality.

As presented in TM-18, the data generated from the chlorine dose response testing is utilized to develop facility and storm event specific disinfection efficacy models. The efficacy models, used in conjunction with log inactivation goals, are able to determine an ICT value required to achieve the bacteria permit limits. ICT stands for integrated residual concentration multiplied by contact time, and has units of mg-min/L. A disinfection control system can utilize an ICT dose pacing algorithm, in lieu of a traditional flow pace system. The advantage of an ICT dose pacing system compared to a flow pacing system is the inclusion of effective contact time. A flow pacing system with a compound loop using a TRC analyzer has a limited adjustment range or may continuously seek if the range is too wide. The ICT dose pacing factors in more variables by incorporating the hydraulic efficiency of a contact volume as well as the chlorine demand and decay rates in the control algorithm. Because of the water quality variability seen in CSO, understanding bacteria loading, chlorine demand and decay rates in real-time is essential to optimizing the chlorine disinfection process.

In addition to providing manual control, this TM will present the following three means of optimizing and controlling the chlorine disinfection process:

- Flow Paced
- ICT Dose Paced with TRC Analyzers
- ML Dosing Model

Understanding how influent water quality is correlated to chlorine demand and decay, and upstream environmental and system characteristics are critical to optimizing the disinfection process. Use of on-line TRC analyzers is one way to determine chlorine demand and decay. Another approach is to utilize ML dosing models to characterize the relationship between upstream characteristics and influent water quality and chlorine demand and decay. This TM presents basic

concepts of ML to help understand the technical vocabulary and the key definitions, modeling approach to be considered during design, general workflow for the prediction model development and deployment, and the project work plan.

The TM is also structured to cover the present disinfection system control, facility Ovation DCS, and sampling system functionality.

Guiding Principles

The guiding principles were developed in collaboration with GLWA for the CSO Improvements Project. The guiding principles provided guidelines for conducting evaluations, identified general areas for improvement, and defined overarching outcomes for the project. **Figure 1-1** summarizes the guiding principles that governed the approach to the disinfection systems evaluation and informed key decisions.

Equipment

- Do not replace equipment in kind – improve equipment
- Provide operational flexibility, cost savings (lifecycle cost basis) including current operational costs
- Reduce human capital and maintenance
- Provide equipment which is accessible and easy to maintain
- Equipment selection to accommodate intermittent use

O&M/System Considerations

- Process must operate reliably “on demand” (intermittent use)
- Keep operations and system improvements simple to extent feasible. Specifically provide a system (or equipment within the system) that can be operated simply in manual mode when needed
- Minimize single points of failure
- Provide sufficient redundancy for each equipment system (balance with reduced O&M)
- Maintain operation of Oakwood and Leib throughout construction phase

Collaboration

- Involve O&M staff in design development process, listen to them and effectively communicate with them
- Design with consistency in materials of construction across disciplines in each room/area

General

- Use same facility, area and room name by all disciplines

Figure 1-1
Summary of Guiding Principles

2.0 Existing System(s) Description (and/or Conditions)

The following subsections describe the disinfection system control, present chemical dosing system, and sampling system at Oakwood and Leib.

2.1 Disinfection System Control

Disinfection system control is implemented manually at local control panels and remotely through the Emerson Ovation DCS. Local control panels provide a manual backup to the Ovation DCS. The Oakwood facility presently utilizes the Ovation DCS platform, while the Leib facility will be upgraded to the Ovation DCS platform under another capital improvement project (CIP) prior to this project being commissioned. The Ovation DCS platform consists of the following components at each facility:

- Redundant root network switches enabling communication between the Ovation process controllers, operator workstations (OWS), database server, and information network.
- Redundant Ovation process controllers (OCR-1100) located in an Ovation controller cabinet with redundant power supplies.
- Input/output (I/O) modules for integrating hardwired signals (digital inputs, digital outputs, analog inputs, analog outputs) into the Ovation system.
- Communication modules for integration of digitally communicated signals from motorized valve actuators, variable frequency drives (VFDs), and third-party programmable logic controllers (PLCs). Communication modules include serial communication modules integrating fieldbus protocols (Modbus RTU, RS-233, RS-485, DF1, etc.) and Ethernet protocols (Modbus TCP/IP, Ethernet/IP, etc.).
- Ovation DCS server housing the database configuration for the facility and enabling modifications, additions, and changes to be implemented locally for equipment and instrument updates.
- Ovation operator workstations (OWS) providing access to the human-machine interface (HMI) graphics for the facility and enabling operations personnel to monitor and initiate control changes for process equipment at the site.
- Communication to the sites is implemented through third-party internet service for normal high-bandwidth communications back to the WRRF. A radio communication link provides back-up communication to the WRRF for transmission of critical signals in the event of the internet communication failure.
- Network communication, data routing, and firewall protection for the sites are provided through Cisco hardware devices.

2.1.1 Oakwood

At Oakwood, each chemical feed pump is dedicated to a storm pump. When the Ovation Control Station begins storm pump operation, the Ovation Control Station will start the storm pump's associated chemical feed pump. In addition, the Ovation control Station will provide a flow value from the flow meter in the storm pump discharge pipe and as a back-up will calculate a flow produced by the storm pump based on speed and wet well level (pump curve). This flow value will be one of the parameters utilized by the Ovation Control Station to calculate the needed chemical feed rate for the chemical feed pump. Additional chemical feed pumps are started as additional storm pumps come online. Each chemical feed pump has a pressure relief valve, suction and discharge isolation valves, and a check valve associated with it as well.

There are three modes of control for each pump – one Manual and two Automatic:

- Manual control from the local control panel (LCP) in the Chemical Facility Control Room.
- Automatic control from the Ovation Control Station. In the automatic mode, programming within the Ovation Control Station can be used to vary the chemical feed pump flow rate in one of two ways, the sodium hypochlorite dose multiplied by Contact Time (also called CT method) or Total Suspended Solids (TSS) method.

CT Method – The feed rate will be based on either the product of chlorine concentration of the initial dose leaving the feed pump and the contact time (maximum CxT=125, minimum CxT=100) or based on a chlorine dose (maximum Cl₂ dose=12.0 mg/L) set point. Based on the set point (CxT or Cl₂ dose) and stored sodium hypochlorite trade percent by weight concentration, the sodium hypochlorite feed rate necessary for the total calculated flow from each storm pump will be calculated.

TSS Method – The total suspended solids (TSS) of the incoming sewage during a wet weather pumping (storm) event is continuously being monitored via a Hach TSS monitor located on the influent sample line in the Influent Sample Room of the Pump Station (PS) Control Building (Status unknown). The Ovation Control System uses a formula that considers the sewage flow rate, the concentration of the sodium hypochlorite disinfectant and the total suspended solids value of the incoming sewage to automatically calculate the hypochlorite dosing rate required to meet the facility's NPDES permit requirements.

The Ovation Control Station is also programmed to start the chemical feed pump to run at maximum speed for an initial period to minimize the time required to fill the discharge pipe with full strength chemical. The maximum run period is an operator adjustable setpoint.

2.1.2 Leib

At Leib disinfection is performed using a CT method (product of chlorine concentration of the initial dose leaving the feed pump and the contact time) (Leib Operations and Maintenance manual referred

as CT). Using the CT method, a constant CT goal (mg/L x minutes contact time) is established, and the disinfectant dose is varied as the contact time changes to maintain the CT goal.

The facility is designed to operate automatically based on programmed controls and feedback from automatic TRC analyzers, but it does not provide control using the CT method. Therefore, operators need to manually input dosages as influent flow rates change. This is accomplished by providing the operators with tables showing the required dosage to achieve the target CT (presently 100 mg-min/L) at various influent flow rates. Operators reference the table for the solution strength closest to the actual analyzed concentration of the present hypochlorite feed solution at the facility. If the facility TRC analyzer is working and accurate, actual dosage concentrations will be recorded automatically. If the TRC analyzer is not operational, TRC will be measured periodically taking samples (a minimum of every ½ hours) from mixing chamber sample pump, and test using colorimeter.

2.2 Sampling System

The sampling system at both facilities is used to monitor water quality at the effluent. The NPDES permit requires the TRC and Fecal coliform to be measured at the effluent of each facility multiple times during a storm event. Grab samples are taken from the effluent sampling system. Sampling systems at both facilities are original and had not been upgraded over time.

2.2.1 Oakwood

The influent sampling system receives flow from sample pumps located in the storm pump station East and West Wet Wells. Influent sample pumps and related piping and valves are installed, the facility influent sampling is not needed for facility operation, so no sampling pumps are used. The effluent sampling system uses one effluent sample pump located in the CSO basin effluent channel just upstream of the CSO basin effluent conduits. The effluent sample pump conveys samples to the effluent sample room, where effluent flow is tested for compliance. The sampling pumps are vertical, heavy-duty, solids handling, non-clogging, and chopper-type pumps. The information of influent sample pumps and effluent sample pumps is presented in **Table 2-1** and **Table 2-2**. As influent sampling is not needed for the operation of facility, influent sampling pumps not in operation. The sampler keypad allows staff to turn the sampler on or off and to program the desired sampling mode(s). Information is displayed on the LED screen. There are three modes of control for each pump:

- Local/Manual control at the Local Control Panel (LCP)
- Remote/Manual control from the Ovation Control Station
- Remote/Automatic control from the Ovation Control Station

Table 2-1 Information of Influent Sample Pumps at Oakwood

Component/Criteria	Value
Service	Influent Sampling
Liquid	Unscreened Combined Stormwater and Wastewater
Name	Influent Sample Pumps Nos.1 and 2
Location	East and West Storm Wet Well Expansion Zones
Number of Pumps	2 (one in each expansion zone)
Configuration	Vertical, Submersible, Chopper type
Design Capacity (gpm:TDH)	144 each, 0.32 cfs, Design total head conditions: 54 ft TDH
Frequency of Pump Starts	4 times in 1 hour
Minimum Efficiency as Design Capacity	20%
Pump Speed at Design Capacity (Maximum)	1750 rpm
Minimum Shutoff Head	50 ft
Maximum Motor Hp	7.5
Net Positive Suction Head Available	36 ft
Pump Discharge Size	3-in
Pump Inlet Size	6-in
Vaughan Model NO. and Impeller Size	SE3M with 8-in impeller

Table 2-2 Information of the Effluent Sample Pump at Oakwood

Component/Criteria	Value
Service	Effluent Sampling
Name	Effluent Sample Pump
Location	CSO Basin Effluent Channel near effluent weir wall which is immediate upstream of effluent conduits
Number of Pumps	1
Configuration	Vertical, Submersible, Chopper type
Design Capacity (gpm:TDH)	120 each, 0.27 cfs, Design total head conditions: 38 ft TDH
Frequency of Pump Starts	4 times in 1 hour
Minimum Efficiency as Design Capacity	35%
Pump Speed at Design Capacity (Maximum)	1750 rpm
Minimum Shutoff Head	44 ft
Maximum Motor Hp	5
Net Positive Suction Head Available	31 ft
Pump Discharge Size	3-in
Pump Inlet Size	6-in
Vaughan Model NO. and Impeller Size	SE3G with 6.5-in impeller

The Influent Sampling Room and Effluent Sampling Room were originally provided with Isco 6712FR composite samplers. The influent sampler has been removed, and effluent sampler is operational. The sampler controller (interface on sampler) will allow mode selection, timer settings, and other parameter settings to be performed locally at the sampler. The Ovation Control Station uses a 4-20 mA totalized flow signal generated from the storm pump flow meters to pace the sampler in the Composite mode and a pulse output to make the sampler sample at a selected flow rate (measured in cfs) of storm pump flow (setpoint adjusted based on operating experience). A selector switch is provided at the Ovation Control Station screen to select between sending flow pacing or quantity pacing signals to the sampler.

2.2.2 Leib

Three EMU constant speed, submersible, grinder pumps are in place at the Leib SDF and Outfall Structure to provide continuous sample of the associated CSO flow during a wet weather event. The first pump is in the Influent Channel, and the second one located in the Effluent Channel just downstream from the Mixing Chamber. Each pump delivers flow to one of the two refrigerated samplers located in the Sampler Room. The sampling pumps in the Influent Channel and Effluent Channel are not in use. A third sample pump is located at the outfall and provides flow to the refrigerated sampler and TRC and oxidation-reduction potential (ORP) monitoring equipment located in the sampling pit at the outfall. **Table 2-3** presents the design criteria of the sample pumps.

Table 2-3 Design Criteria of the Sample Pumps at Leib.

Component/Criteria	Value
No. Sample Pumps	3
Size	2 inches
Type	Submersible Grinder
Capacity	50 gpm @50 ft TDH
Motor	4.7 HP, 460 V, 3480 rpm, 3 Phase

Two Isco 6700 refrigerated samplers are in the Sampler Room of the Control Building, and one is in the sampling pit at the Outfall Structure. Of the two samplers located in the Sampler Room, one is for the untreated flow that is pumped from the Influent Channel and the other one is for the screened and disinfected flow in the Effluent Channel. The controllers for the samplers contain two programming modes, standard and extended, with a keypad for program entries. Standard programming allows to set up typical sampling program easily and efficiently while the extended mode allows for more sophisticated and complex program.

The TRC analyzer system, manufactured by Capital Controls, consists of an amperometric analyzer and a millivolt to current transducer measuring free or total residual chlorine. The unit associated with the facility discharge sample pump is located in the Control Building, while the unit associated

with the outfall is located in the outfall sampling pit. The Outfall Sampling unit is turned off because there is no potable source for standby operation.

Sample is delivered to the sample-screening chamber of the TRC analyzer at an approximate rate of 500 ml/min. The excess overflows to drain. The sample then passes into a measuring cell of the flow-thru type with two dissimilar metal electrodes, which produces a signal proportional to chlorine residual. During non-operational / sampling periods the TRC Analyzer in the facility sampling room is fed a continuous stream of clean water. This water stream allows the TRC unit to maintain its calibration between wet weather event samples. This water stream will automatically be shut off when the effluent channel sample pump and sampler are activated. Shutoff is accomplished by closing a solenoid valve on the water supply line. The valve is wired to the sampler.

3.0 System Evaluation

This section presents the evaluation of operation of the existing chlorine disinfection system operation and sampling system at Oakwood and Leib.

3.1 Disinfection System

3.1.1 Oakwood

The Ovation Control Station provides a flow value from the flow meter in the storm pump discharge pipe. This flow value is one of the parameters utilized by the Ovation Control Station to calculate the needed chemical feed rate for the chemical feed pump. The reliability of storm pump flow measurement came into question, and an evaluation of the reliability of the flow meters is part of this project which is not covered under this TM.

Operators indicated that presently the sodium hypochlorite feed pumps are operated manually with manual TRC measurements used as a guide to make changes to the sodium hypochlorite flow rates. TRC check is done by grabbing the sample at the screen facility, upstream of screens and analyzing for TRC with a Hach device. Based on the first TRC check, the sodium hypochlorite feed rate is adjusted.

As the storm flow measurement is questionable, operators do not rely on the sodium hypochlorite flow rate determined by the control system as it is not providing reasonable dose in their assessment. Thus, the operators tend to use high sodium hypochlorite feed rates to make sure the required disinfection is being achieved. Recent site visits during storm events, it was observed that the high sodium hypochlorite feed rates early in the storm events results in chlorine off gassing being observed where the storm pump discharge into the screening chamber. Excessive chlorine off gassing may result in corrosion of metal items and be a health and safety concern in the vicinity.

3.1.2 Leib

The operator indicated that the sodium hypochlorite feed at the pre-chlorination mixers is manually operated while the feed at the mixing chambers is automatic. Operator enters in the

control system the stored sodium hypochlorite trade percent by weight concentration and the sodium hypochlorite application rate based on the CT tables from operation and maintenance manual. The control system paces the sodium hypochlorite feed rate to achieve sodium hypochlorite application concentration. As the influent flow rate changes, the operator adjust the sodium hypochlorite application rate based on the CT tables from operation and maintenance manual. The effluent TRC analyzer is not in operation and does not provide feedback in sodium hypochlorite feed rate.

3.2 Sampling System

3.2.1 Oakwood

Influent sample pumps and related piping and valves are installed, but not used since the CSO operators aren't in need of them to operate the facility. Therefore, the influent samplers were removed from Oakwood. If the influent sampling is to be used, the influent pumps should be replaced instead of reusing them.

3.2.2 Leib

The sampling pumps in the Influent Channel and Effluent Channel are not in use. Thus, the samplers for the untreated flow from the Influent Channel and the screened and disinfected flow in the Effluent Channel were removed. The Outfall Sampling unit was turned off because there is no potable water source for standby operation.

4.0 Description of Alternatives

4.1 Disinfection Control Functionality

The four modes of controlling the chlorination system will be:

1. Manual Control
2. Flow Paced
3. ICT Dose Paced with TRC Analyzers
4. ML Dosing Model

TM-18 summarized the results from the disinfection modeling and recommended the high and average ICT values for both Oakwood and Leib. TM-20 further determined the sodium hypochlorite dose for the respective ICT values based on the sodium hypochlorite solution. For Oakwood, TM-20 also determined the dose for CSO basin with baffles. The stored sodium hypochlorite trade percent by weight concentration and ICT values will be key parameters in determining the sodium hypochlorite feed rates under four control methods.

4.1.1 Manual Control

In this mode the sodium hypochlorite feed system will be started, stopped, and controlled manually from either local control panel or Ovation Control System. Operators will use the selected ICT value,

the stored sodium hypochlorite trade percent by weight concentration, and inputs from storm flow meter(s) to determine the sodium hypochlorite feed rate. If the online TRC analyzer sampling system is implemented, it will provide tool to manually adjust the feed rate.

Manual control will not have automation and will be based on the operator's familiarity with the CSO and chlorination system, experience with the system and operational judgement. It will have lowest data requirement, no complex instrumentation. This control will require the use of higher safety factors in sodium hypochlorite feed rates to account for the uncertainty to achieve required disinfection and increasing sodium hypochlorite usage and costs and potential corrosion due to high sodium hypochlorite dose and off gassing of chlorine at the downstream processes. Also, it will need more manual operation and staff involvement.

4.1.2 Flow Paced

In this mode the chemical feed system will be started, stopped, and controlled based on the flow inputs from the flow meter(s). Operators will select the chlorine dose, input the stored sodium hypochlorite trade percent by weight concentration, and the control system will automatically adjust the chemical feed rate based on the influent flow to the CSO facility.

Flow paced control will have less amount of automation compared to the ICT dose paced with TRC analyzers and ML dose model modes as only related to the influent flow and chemical feed rate. It will have lower safety factor than the manual mode and will result in sodium hypochlorite savings compared to the manual control mode which could potentially overshoot sodium hypochlorite dose to achieve required disinfection. This control will require less manual operation and staff involvement than the manual control mode.

4.1.3 ICT Dose Paced with TRC Analyzers

The efficacy models, used in conjunction with log inactivation goals, are able to determine an integrated CT (ICT) value required to achieve the bacteria permit limits. ICT stands for integrated residual concentration multiplied by contact time and has units of mg-min/L. A disinfection control system can utilize an ICT dose pacing algorithm, in lieu of a traditional flow pace system. The advantage of an ICT dose pacing system compared to a flow pacing system is the inclusion of effective contact time. A flow pacing system with a compound loop using a TRC analyzer has a limited adjustment range or may continuously seek if the range is too wide. The ICT dose pacing factors in more variables by incorporating the hydraulic efficiency of a contact volume as well as the chlorine demand and decay rates in the control algorithm. The flow rate is utilized in the algorithm to calculate an effective contact time, and the chlorine demand and decay are included in determining the sodium hypochlorite flow rate. The stored sodium hypochlorite trade percent by weight concentration is also an input into this control approach. The initial ICT can be adjusted in future years based on the historical data and additional upstream water quality sampling and analysis.

Two TRC analyzers will be utilized, one shortly after chlorine addition, and the second further down the contact volume. The first TRC analyzer will allow for the chlorine demand to be

determined, while the second TRC analyzer will allow for the chlorine decay to be determined. These inputs into the ICT model will allow for real-time adjustment to the chlorine dose based upon the changing water quality and contact times observed during storm events. In-lieu of using online TRC analyzers, operator can elect to enter chlorine demand and chlorine decay value based on the seasonal variation typically observed in CSO collection system. The on-line TRC analyzer details are presented in Section 4.2.

This control method provides confidence by using data driven disinfection optimization to reduce the amount sodium hypochlorite used while meeting permit limits. It will have less manual operation and staff involvement. The continuous data collection by analyzers will incrementally improve dosing algorithm. This control mode will involve a higher degree of automation and higher capital investment in analyzers and SCADA integration than manual control and flow paced modes.

4.1.4 Machine Learning Dosing Model

Influent water quality is correlated to chlorine demand and decay, and upstream environmental and system characteristics have a large impact on the influent water quality. ML dosing models are looking to characterize the relationship between upstream flow characteristics, influent water quality and chlorine demand and decay. Because chlorine decay is typically quite small, the focus will be on chlorine demand which changes significantly based upon the influent water quality. This section presents a technical approach related to the studies and alternatives development to delineate the design process to evaluate the feasibility of incorporating modification of the CTI approach and the potential for a ML dosing model to optimize system operation across multiple flows and bacterial loading scenarios estimating. The evaluated model will be trained to optimize disinfectant usage by learning from historical system performance after one (1) year of operation post upgrades. Correlations between upstream online analyzer data and disinfection performance will be investigated to determine if they can optimize chemical dosage in a broader range of conditions. If more data is collected after the first year of operation, a ML model could be continuously retrained to improve its accuracy over time. This subsection will provide information on the basic concepts, chlorine demand and decay prediction model approach, ML workflow, and project work plan.

4.1.4.1 Basic concepts of Artificial Intelligence (AI) and Machine Learning

AI focuses on developing human-like intelligence systems, with ML as a subfield creating algorithms for computers to learn and recognize patterns. ML models are categorized into supervised learning (trained on labeled data for predictions) and unsupervised learning (identifying patterns without initial labeling). These algorithms utilize data for training to generate predictive models for new data, differing from deterministic programming-based process control algorithms. **Figure 4-1** presents example plots showing supervised learning and unsupervised learning.

Figure 4-1
Supervised and Unsupervised Learning

ML problems include classification and regression. Classification groups data based on predetermined characteristics, such as categorizing water reservoir statuses using dissolved oxygen and total organic carbon values. Regression models continuous relationships between variables, like estimating manganese levels in a reservoir using pH, TOC, DO, and temperature. Examples of classification and regression plots are presented in Figure 4-2.

Figure 4-2
Classification and Regression Problems

Model performance metrics evaluate ML model accuracy and effectiveness. Regression metrics include Mean Absolute Error (MAE), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), and R-squared. Classification metrics encompass accuracy, precision, recall, and F1-score. The choice of metric depends on the problem type, data nature, and desired outcome.

4.1.4.2 Chlorine Demand Prediction Model Approach

The ML problem to be resolved requires the development of a supervised regression model to predict chlorine demand based on CSO flow, environmental factors, and upstream properties. During the project's design phase, various methods will be used to characterize influent water quality parameters. The process involves developing and evaluating two cascade models. The first model estimates influent forecasts using data from the Oakwood pump station, weather stations, and rainfall metrics. This model also characterizes CSO flow events for optimization. The second model utilizes influent flow forecasts and water quality data to estimate chlorine demand. Two initial approaches, Chlorine Demand Prediction (CDP) and Chlorine Dosage Model (CSP), are considered, with the possibility of an additional modeling approach during the design phase. The ML models estimate the chlorine demand based on environmental and upstream characteristics. Influent water quality parameters can be characterized by several approaches that will be defined during the project's design phase. However, in general terms, the initial approach requires the evaluation and development of two models in a cascade. The first model will be oriented to estimate the influent forecast to determine the surge of flow correlated with the influent pumps station (Oakwood), real-time weather station, etc., to capture point estimates of rainfall intensity and duration. The flow model evaluation also includes the characterization of the flow CSO event in terms of its applicability to the overall optimization objective. This characterization includes determining whether it is practical to estimate the Chlorine demand over real-time values of CSO influent flow/level or window horizon of the CSO flow inrush flow has value for operational purposes. The second model will use the influent flow forecast or real time values as input and water quality data to estimate the chlorine demand. Having the Chlorine demand estimated by the ML model, the control approach could be to implement a model predictive control to optimize the chlorine injection based on the trajectory of the Chlorine demand or provide the information to the operator on the DCS in advisory mode. For Chlorine demand prediction, two initial approaches are considered. However, additional approaches may be considered during the design phase. The two models' approaches are Chlorine Demand Prediction and Chlorine Dosage Model.

Chlorine Demand Prediction (CDP)

The **CDP** model is intended to predict changes in the present chlorine demand using the historical chlorine dosage, collected during a year of operation, TRC, and upstream water characteristics such as organic load, precipitation data, radar imagery, flow information, and date-time information. This information will be used to calculate changes in chlorine dosage based on the ICT value to be

shown in an advisory mode or automatic change of setpoint in the Distributer Controller System (DCS). Process of CDP model training and deployment is presented in **Figure 4-3** and **Figure 4-4**.

Figure 4-3
 Chlorine Demand Prediction (CDP)_Model Training

Figure 4-4
 Chlorine Demand Prediction (CDP) Model Deployment

Total Residual Chlorine Limit

The CSP model intends to predict changes in chlorine dosage based on historical data such as present chlorine dosage, desired TRC limit, and upstream water characteristics such as organic load, precipitation data, radar imagery, flow information, date-time information, etc. The optimal dosage could be predicted by providing the model's expected TRC limit and present condition. The new setpoint could be provided in an advisory mode in the DCS or an automatic change of setpoint in the DCS. Process of CSP model training and deployment is presented in **Figure 4-5** and **Figure 4-6**.

Figure 4-5
Chlorine Dosage Model (CSP) Training

Figure 4-6
Chlorine Dosage Model (CSP) Deployment

4.1.4.3 Machine Learning Workflow

Data Identification and Collection: In this phase, defining variables and sensors for model training is crucial for feature selection and accuracy. Preparing the DCS and other data sources to collect necessary information involves selecting appropriate sensors and data. This step is vital for developing an accurate model and considers various sensors as potential candidates. The following sensors, but not limited to them, will be considered:

- Ground/Well levels and flow IoT sensors + weather stations and National Oceanic and Atmospheric Administration (NOAA) radar imagery and Sewer distribution flows
- Influent flow metering data and pump stations effluent data
- Hydraulic model data
- Water Quality Data
 - TSS
 - Turbidity
 - Chemical Oxygen Demand (COD)
 - Total Organic Carbon (TOC)
 - UV Absorption (UVA)
 - pH
 - Temperature
 - TRC influent, TRC mid-contact basin, and TRC effluent
 - Bacteria activity from online analyzers for E. coli and an organic surrogate (ColiMinder™)

During this phase, assistance to the Instrumentation and Control (I&C) designer will be provided to establish instrumentation selection and the metrological aspect of the data collection, including accuracy, sensibility, repeatability, calibration accuracy, calibration frequency, etc.

Data Collection Design

The problem approach involves building a ML model using data from various sources including online data from DCS on water quality parameters, asynchronous laboratory results on similar or additional quality parameters, and data from physically distributed well level, flow, and rain gauge samples.

To synchronize the data from different sources, the following design considerations need to be incorporated:

- Time alignment is crucial as data is produced at varying intervals. Aligning data to a common time frame, such as resampling and event labeling, ensures consistency across different data sources like DSC real-time data, distributed level and flow data, rain gauges, and autosampler laboratory data.
- Data imputation involves inputting autosampler laboratory results and rain gauge data into the selected time frame and event. Rain gauge data provided in daily records must be adjusted to include datetime labels and logged every 15 seconds during rain events..
- Data integration involves merging data from various sources into a single dataset using common identifiers like date-time and flow. For instance, laboratory results can be linked to DCS data through CSO event labels and flow information.

Data Preprocessing: Once the data is collected, preprocess the data by cleaning, filtering, denoising, and transforming the data into a format suitable for analysis. This may include handling missing values, dealing with outliers, and normalizing or standardizing the data.

Exploratory Data Analysis (EDA): This involves examining and visualizing the data to understand its characteristics, identify patterns using unsupervised modeling, and gain insights that can guide the modeling process. In the context of time series analysis with cross-correlation for multivariate analysis, the process of EDA can be broken down into several key steps, described below.

- Data Collection: The first step in the EDA process is to collect the relevant data, including multiple time series and their associated variables.
- Data Cleaning and Preparation: Once the data has been collected, it needs to be cleaned and prepared for analysis. This involves removing missing values and outliers and normalizing or transforming the data.
- Exploratory Data Analysis: The next step is to conduct exploratory data analysis, which involves visualizing the data to identify trends, patterns, and relationships. This can be done with various techniques, such as scatter plots, line charts, histograms, and box plots. This phase will include the possible development of clustering analysis using unsupervised learning looking to evaluate flow pattern between the rain gauges, sewer level and flows.

Time Series Analysis: After conducting the EDA, the next step is to perform a time series analysis. This involves analyzing the data for trends, seasonal patterns, and other temporal effects and estimating and modeling any relevant time series models.

Cross-Correlation Analysis: Identify lagged relationships between series and determine which variables most predict the target variable.

Multivariate Analysis: Examines the relationship between multiple variables and how they influence each other using unsupervised algorithms as principal component analysis (PCA) or factor analysis to help identify underlying patterns and relationships between variables.

Feature Selection: Identify relevant features from the collected data likely to be correlated with the chlorine demand. This may involve analyzing correlations between variables, identifying relevant variables defined by context knowledge experts, or using ML algorithms such as PCA or LASSO (Least Absolute Shrinkage and Selection Operator) to identify the most relevant features.

The feature selection process must be particularly important to developing a model because it intends to filter data that may not be valuable for an accurate prediction. For example, CDM Smith's experience with NOAA radar imagery for precipitation and flow forecast had been the challenge in providing accurate estimation for near real-time prediction because the NOAA radar transmits a few seconds every hour. Another factor that does not favor a near real-time prediction is the nature of technology based on doppler radar designed to measure reflectivity at an elevation that made the prediction of the approximate location of the precipitation and concurrent effect of a CSO influent flow quite challenging. For this purpose, distributed IoT sensors for rain, wet level, and sewer and storm flow have shown to be the preferred features for the understanding of the dynamics of flow on time series as documented in several research publications including:

- Hazhar Sufi Karimi et al, "[*Comparison of learning-based wastewater flow prediction methodologies for smart sewer management*](#)", Journal of Hydrology, Volume 577, 2019, 123977
- Zhang, Duo, Geir Lindholm, and Harsha Ratnaweera. "[*DeepCSO: Forecasting of combined sewer overflow at a citywide level using multi-task deep learning*](#)." arXiv preprint arXiv:1811.06368 (2018).

The correct selection of the water quality parameter is key to achieving acceptable chlorine demand prediction. Although there are not many research papers related to chlorine demand prediction, research papers targeting chlorine residual prediction for drinking water have shown an increase in accuracy prediction when the model is built with at least three water quality input parameters. Examples of this approach are published in:

- Wadkar, Dnyaneshwar & Kote, Alka. (2017). [*Prediction of residual chlorine in a water treatment plant using generalized regression neural network*](#). International Journal of Civil Engineering and Technology. 8. 1264-1270.
- Wiley Speir Helm , "[*Master's Thesis titled Machine Learning Applied to Chlorine Residual Data*](#)"

Model Development: Developing an ML model to predict the chlorine demand will be performed by the training using different existing ML algorithms, such as linear regression, decision trees, random forests, support vector machines, and neural networks. The model development may

include performing Ensemble techniques that combine multiple models to make a more accurate prediction than a single model. The specific algorithm chosen will depend on the amount and quality of data available and the desired level of accuracy.

Model Evaluation: Evaluate the performance of the developed model using appropriate metrics such as MSE, RMSE, R-squared, or other suitable performance metrics. The model's performance will be evaluated using cross-validation techniques or splitting the data into training and testing sets. Model training will utilize 70-80% of the data gathered, while the remaining 30-20% of the data will be used to test the model. The selected performance metrics will be used to determine the accuracy of the model, and thus its feasibility.

Model Optimization: Optimize the model by fine-tuning the model parameters or exploring alternative algorithms and re-evaluating the model's performance.

Machine learning workflow diagram is shown in **Figure 4-7**.

Figure 4-7
Machine learning Workflow

ML model implementation (Edge Computing):

Deploying an ML model on Edge Computing involves running it in a local Industrial Processor instead of a centralized cloud server. Edge Computing could be done by a state-of-the-art ML module installed in the backplane of a PLC or by an industrial PC with communication integration capabilities. See **Figure 4-8**, showing typical edge device implementation architecture.

The facility's edge computer would be used to provide inputs to and outputs from the Ovation system for process analysis. This computer could be developed to operate in advisory mode or control mode. In advisory mode, it would indicate a recommended value that should be used in the facility operations. Then the operator has to make a decision and change the setpoint. In control mode, the Edge computer would send the set point directly to a PLC/control system and modulate the dosage.

Figure 4-8
Typical Edge Device Implementation Architecture

4.1.4.3 Project Work Plan

This work plan aims to develop a ML model to predict the chlorine demand in a CSO process. The CSO process is a key component of wastewater treatment systems and understanding the chlorine

demand is crucial for ensuring effective treatment. To achieve this goal, the work plan includes three main phases: the design phase, the construction phase, and the developing phase.

In the design phase, the tasks involve gaining a deep understanding of the context and instrumentation of the CSO process, selecting relevant variables, designing the data source, and sampling strategy, research review and conducting exploratory data analysis on historical records, defining the model metric.

The construction phase includes a submittal review of sensors, data, hardware, and software components to ensure the components meet the goal of the intended design will be provided. This phase also includes commissioning verification and data collection quality validation during the operation.

Data quality verification and validation is crucial during the process of collecting data from sensors for ML modeling. The quality of the data directly affects the performance and accuracy of the ML models, and inaccurate or unreliable data can lead to incorrect predictions and decisions. The most common reason why data quality validation is important:

- Accuracy: If the data collected from sensors is inaccurate or unreliable, the resulting models will be inaccurate as well.
- Completeness: Missing or incomplete data can cause issues with the model's accuracy and reliability.
- Consistency: Inconsistent data can also lead to inaccuracies in ML models. Data quality validation can ensure that data is consistent and meets the required standards.
- Outliers: Data quality validation can help identify outliers and determine whether they should be removed or corrected.
- Bias: Biased data can lead to biased models, which can have serious consequences in certain applications. Data quality validation can help identify and correct bias in the data.

After a minimum of one year of data collection, the developing phase will begin. This phase focuses on modeling following the workflow described above.

Design Phase Tasks

1. Research review of related modeling projects.
2. Develop alternative analysis to define model approaches for influent flow forecasting.
3. Develop alternative analysis to define model approaches for Chlorine demand prediction.

4. Field sensor evaluation and selection, data collection for preliminary Analysis, and concept modeling.
 - a) Sensor for estimation of rainfall intensity, duration, and influent flow.
 - b) Sensor evaluation to identifying surrogates for chlorine demand or TRC.
 - c) Develop alternative analysis for to ensure the quality and accountability of the data collected, evaluating the following three alternative.
 - i) Permanent metering infrastructure with maintained by contractor or owner.
 - ii) Turnkey monitoring analyzer panels with maintenance and calibration services.
 - iii) Sensor leasing with maintenance and calibration services and data collection services.
5. Develop alternative analysis and specification definitions for the qualifications of the ML engineering service provider.
6. I&C consultancy during control design and context knowledge analysis for instrumentation and variables selection, sampling infrastructure, sensor selection, and online data collection.
7. Model metric definition and analysis.
8. Develop training and testing specification.

Construction Phase

- 1) Submittal review of sensors, data, sensors, analyzers, and software components.
- 2) Commissioning Data collection quality verification.
- 3) Operation Data collection quality validation.

Modeling Developing phase (After a minimum of one year of data collection)

- 1) Historical records Exploratory Data Analysis
- 2) Influent forecast Model development
- 3) Chlorine demand Model development
- 4) Models testing and performance metric evaluation.
- 5) Develop result reports and recommendations.

Risks Involved

There are certain aspects of this project that involve a certain level of uncertainty either due to data availability or level of detail associated with data which presents a risk to the project. Such potential risks may include:

- The rainfall data that may not be available at the horizon intervals required by the controls while other data from analyzers will be available at finer time intervals.
- Problems with the analyzers and other sensors may not be known until the data is adequately analyzed.
- Since CSO events are rare, the model's performance may depend on the quantity of data available. It is possible that one year of data may not provide enough information to create an accurate model.
- Model performance also relies on data quality. Thus, selecting the appropriate analyzer skid alternative and ensuring data quality during the collection period are crucial for the feasibility analysis's success.

4.2 Analyzer Type

Chlorine residual analyzers are available in manual (handheld) and on-line types. A manual (handheld) chlorine residual analyzer enables quick analysis of grab samples. On-line chlorine residual analyzers provide output capability to a process control system or DCS. For on-line chlorine residual analyzers, two technologies are typically utilized to determine the total chlorine residual. Amperometric units, such as the HACH CL10sc, use two electrodes (anode and cathode) that measure a change in current caused by the chemical reduction of hypochlorous acid at the cathode. The current generated due to this reduction is proportional to the concentration of chlorine. Amperometric units are suitable for a flow stream that provides a relatively constant pH range. For applications with wide pH range, some manufacturers provide extended pH range sensor or include a pH sensor to compensate for the change in pH. Colorimetric (DPD) analyzers use reagents and a buffer solution to react with the active free chlorine to generate a colored product that is read photometrically to identify the amount of chlorine present. The HACH CL17sc analyzer widely utilized throughout GLWA uses this method of measurement. **Table 4-1** identifies the ranges, reagents, flow requirements, and typical manufacturers for both types of on-line chlorine residual analyzers.

Table 4-1 On-line Total Chlorine Analyzer Attributes

Analyzer Type	TRC Measurement Range, mg/L	Basis of Technology	Reagents for CSO Applications	Continuous Liquid Flow Required	Manufacturers
Amperometric	0-20	Uses electrode in flow through cell to electric current as a surrogate for TRC	Buffer Electrolyte solution Iodide solution	Yes	Evoqua Micro/2000; Hach CLT10sc
Colorimetric	0-10	Uses reagents for DPD chlorine reaction and analyzer measures color at a given wavelength as a surrogate for TRC	Buffer Iodide solution	Yes	Hach CL17sc SWAN AMI Codes-II TC (Selected for design)

Critical to the operation of the TRC analyzers is the routine maintenance required for either amperometric or colorimetric units. Amperometric units must ensure pH levels are remaining within the unit range or the unit is calibrated to a new pH level if a pH probe is not integrally provided with the unit. Colorimetric units must be routinely checked to ensure adequate reagent and buffer solution is available to the unit. This process becomes critical when utilized on facilities where intermittent use of the analyzers will occur. Routine maintenance must also include regular calibration of the units. Calibration and maintenance will be essential to obtaining accurate inputs to the control system or ML algorithms.

Microbial Water Quality Analyzer

Advances in real-time microbial water quality analysis have paved the way for utilizing a fully automated, rapid on-line analyzer that is able to estimate bacteria enumeration. Vienna Water Monitoring Solutions (VWMS) has developed the ColiMinder™, which is able to measure *Enterococci*, *E. coli*, and total activity. Traditionally enumerating bacteria is a 24- to 30-hour process, most of which is incubation time to allow the bacteria to grow colonies that are large enough to see and count with the naked eye. The ColiMinder™ directly measures the enzymatic activity of a water sample as a surrogate for bacteria concentration, allowing for enumeration to be provided in 15 minutes. This technology may be a significant step forward in optimizing disinfection processes. The analyzer is not fully developed for the intermittent CSO application. However, an adaptation of the technology for on-demand CSO monitoring is basically possible. An operation mode for the ColiMinder™ in which operation is triggered by events would need to be developed, implemented and tested. Further investigation will be needed to evaluate the feasibility of the full-scale pilot testing. A successful pilot will test and provide ability to monitor influent and effluent bacteria counts against flow rates at the facilities to optimize the disinfection process across flow rates during individual wet weather events, and the seasonal variations typically seen in CSO collection systems.

Summary of on-line analyzers recommended for Oakwood and Leib is presented in **Table 4-2**.

Table 4-2 On-line Analyzers Recommended for Oakwood and Leib Applications

	Analyzer Type	Analyzer Type	Manufacturers	Models	Measurement Range	Require Continuous Flow?
1.	TRC	Colorimetric	HACH SWAN	CL17sc Colorimetric AMI Codes-II TC Colorimetric	0 - 10 mg/L	yes Not needed but advantageous
2.	TSS	Sensor	HACH	Solitax sc INSERTION highline sc Solitax sc INSERTION inline sc	0.001 mg/L to 500 g/L 0.001 mg/L to 50 g/L	yes
3.	COD	REDOX Titration after oxidation by potassium dichromate solution, conform with ISO 6060 method	HACH	EZ7000 Series	5-10000 mg/L O ₂	yes
4.	Turbidity	Sensor	HACH	Solitax sc INSERTION highline sc or Inline TU5 Series	0.001 to 4000 NTU 0.001 to 1000 NTU	yes yes
5.	Temp/pH	Sensor	HACH	Digital pHD sc sensors	-5 - 70 °C (23 - 158 °F) pH and ORP 0 - 50 °C (32 - 122 °F) SS pHD/-2.0 to 14.0 pH	yes
7.	TOC	Infrared	HACH	B3500e	0 - 250 mg/L C, 0 - 1000 mg/L C	yes
8	UVA	UV absorption	HACH	UVAS PLUS sc SENSOR	0-50 mm	yes
9	Bacteria Indication (<i>Enterococci</i> , <i>E. Coli</i> , and total activity)		Vienna Water Monitoring Solutions (VWMS)	ColiMinder™ (see note 1)		

Note: 1. Full scale pilot testing evaluation for CSO application is recommended.

4.3 Sampling System Functionality

The two approaches to water quality sampling at Oakwood and Leib are manual/grab and automatic/online. The manual/grab sampling is labor intensive and requires additional efforts during storm events. The time period required in manual/grab sampling and lag in getting results will reduce efficiency in optimizing the chemical dose and will result in a higher factor of safety and higher chemical dosing. The automatic/online sampling will have benefit for the on-line analyzers to measure parameters in real time and provide inputs to the Ovation DCS. The real time parameters measurement will be necessary for the sophisticated automation of the disinfection control system. The automatic/online sampling will need extensive sample collection system with sample pumping and piping and returning the sample back. It will have additional equipment to maintain.

4.2.1 Oakwood

Influent Sampling System

Influent water quality sampling is necessary for ML model training to further optimize disinfection. The two influent sampling pumps have not been used for an extended period of time, therefore instead of performing pump condition assessment, it is proposed to replace the pumping system with similar type. During basis of design phase, the feasibility of reducing flow capacity and option of Flygt N series pump will be evaluated. The influent sample piping could be potentially reused. During detailed design, the condition assessment of piping can be done. The influent sampling system is presented in **Figure 4-9**.

Figure 4-9
Oakwood Influent Sampling Pumps and Piping System

As part of the ML model training, new online analyzers are proposed to monitor the TRC, TSS, COD, turbidity, temperature/pH, TOC and UVA. Hach provides TRC, multi-parameter and COD analyzers. **Figure 4-10** presents the proposed location of analyzer panels inside the Influent Sample Room.

Figure 4-10
Oakwood Influent Sampling and Analyzers Proposed Location

Chlorine Demand Sampling System at Screen Inlet Chamber

TRC sampling shortly after chlorine addition will allow for chlorine demand to be determined. Ideally the sampling location will provide a 30 second to 120 second contact time between the application point and the TRC analyzer. Based on the contact time for respective storm pump discharge standpipe and flow scenarios, and the CFD modeling results the proposed location for sampling is Screen Inlet Chamber. **Table 4-3** presents the calculated contact times for different flow conditions. Multiple sampling locations will be needed to cover the different flow scenarios, operation of different storm pumps, and different screens in operations. **Figure 4-11** presents the option of six sampling locations paired with three sample pumps, and TRC analyzer location. The sample pumps in this option will be self-priming trash pumps. The sample pump and analyzer location inside the Screen Room was eliminated due to the hazard classification of Class 1, Division 1, Group D of the Screen Room. **Figure 4-12** presents the three submersible sample pumps and TRC analyzers located outside of Screen Room on the roof of Screen Inlet Chamber. The chlorine demand and chlorine decay TRC analyzers will be housed inside the FRP enclosure with necessary HVAC equipment. **Figure 4-13** shows option of location TRC analyzers inside the Mechanical Room of the Screen Facility. The feasibility of this location with respect to the available space and implication on the hazard classification of the Mechanical Room due to the drain from sampling piping or analyzer will be further evaluated during the Basis of Design phase.

Two TRC analyzers one duty and one redundant will be provided. On the shelf spare for sample pumps will be utilized for redundancy.

Table 4-3 Estimated Contact Time for Chlorine Demand TRC Sample Location at Screen Inlet Chamber for Different Flow Conditions

Flow Conditions	Flow, Cfs/MGD	Estimated Contact Time ¹ , seconds	Assumed Pumps in Operation
Minimum Flow	99/64	51 ²	One small pump
Avg Flow – Existing Collection System	135/87	82 ²	Two small pumps
Avg Flow – Future Collection System Configuration	531/343	42	Two small, one large pumps
Peak Flow - Existing Collection System	765/494	30	Two small, one large pumps
Peak Flow – Future Collection System Configuration	1,231/794	32	Two small, four large pumps
Design Peak Flow	1,660/1,071	28	Two small, five large pumps

Notes:

1. Conveyance through the sampling piping will add contact time up to 20 seconds (assumed 100 feet pipe at 5 velocity 5 fps) at TRC analyzer location.
2. Contact time assumed based on the sample location near the small pump discharge pipe.

Oakwood Chlorine Demand Sampling at Screen Inlet Chamber and TRC Analyzers on Roof

Page 39

TM-19 Chlorine System Automation Evaluation.docx

Chlorine Decay Sampling System at CSO Basin

To determine the real-time chlorine decay, a new sample pump and TRC analyzer can be installed in the CSO Basin. The input from chlorine decay TRC analyzer will allow for real-time chlorine decay values to be provided to the control algorithm based upon the changing water quality and contact times observed during storm events. The proposed sample location will be inside each CSO basin downstream of oil/grease baffle at approximately 120 feet from the CSO basin influent gates. This will allow the TRC to be measured during the first 15-30 minutes of contact time, and it allows TRC values to be measured even during the fill-draw storm events that do not result in the overflow over effluent weir to effluent channel to outfall. If baffle configuration of CSO Basin is selected, the sampling location could be further evaluated during detail design. The Oakwood CFD model of the CSO basin to help determine a representative elevation and distance from the basin wall for the chlorine decay sample point. The future sewer collection system configuration with the Northwest Interceptor interconnection (NWI) will have significantly higher average storm flows and the sample pump will need to be relocated further downstream. These sampling pumps will be similar to influent sampling pumps. On the shelf spare pump will be utilized for sample pump redundancy. To facilitate access/removal of these sampling pumps, new access hatches will need to be cut into the top of the basin roof. The Two TRC analyzers one duty and one redundant will be provided. TRC analyzers will be located next to the proposed TRC analyzers for chlorine demand. **Figure 4-14** presents the proposed sample pumps location.

Figure 4-14
Oakwood Chlorine Decay Sampling at CSO Basin

Effluent Sampling System

The existing effluent sample pumping and piping system will be kept. New online analyzers are proposed to continue monitoring parameters required for NPDES permit compliance. Each provides multi-parameter analyzer and COD analyzer. **Figure 4-15** presents the proposed location of analyzer panels inside the Effluent Sample Room.

Figure 4-15
Oakwood Effluent Sampling and Analyzers Locations

The sampling system functionality recommendations for Oakwood are summarized in the **Table 4-4**.

Table 4-4 Recommended Sampling System at Oakwood

Sampling System	Sample Location	Sample Collection System	Sampler /Analyzer Location	Parameters	Need
Influent Sampling System	Influent East and West Wet Wells	- Replace existing influent sample pumps with similar type - Reuse existing sampling piping	Influent Sampling Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	At Screen Inlet Chamber upstream of screens	- Three sample locations between pump discharge standpipes and screen inlets. - Three submersible sample pumps located in Screen Inlet Chamber	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System	One sample location at each CSO basin before effluent weir	One sample pump at each CSO Basin before effluent weir	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Effluent channel	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

4.2.2 Leib

Influent Sampling System

Influent water quality sampling is necessary for ML model training to further optimize disinfection. The influent sampling pump has not been used for an extended period of time, therefore instead of performing pump condition assessment, it is proposed to replace the pumping system similar type. During basis of design phase, option of Flygt N series pump will be evaluated. The influent sample piping could be potentially reused. During detailed design, the condition assessment of piping can be done. As part of the ML model training, new online analyzers are proposed to monitor the TRC, TSS, COD, turbidity, temperature/pH, TOC and UVA. Hach provides TRC, multi-parameter and COD analyzers. **Figure 4-16** presents the location of influent sample pump. **Figure 4-17** shows proposed location of analyzer panels inside the Influent Sample Room for analyzers.

Figure 4-16 Leib Influent Sample Pumping System

Figure 4-17
Leib Influent Sampling and Analyzers Locations

Chlorine Demand Sampling System at Screen Inlet Chamber

TRC sampling shortly after chlorine addition will allow for chlorine demand to be determined. Ideally the sampling location will provide a 30 second to 120 second contact time between the application point and the TRC analyzer. The existing effluent channel sample pump location will provide an estimated contact time between 14 seconds at peak flow for future sewer collection system configuration and 73 seconds for average flow of 50 cfs. For a more representative sample, it is recommended that the location of the sample pump be moved into the center line of the channel. While this location will have challenges associated with providing access (via new access hatch at grade and structure from the channel roof to grade) and supporting the guide rails, this

location will provide for a more representative demand sample. Alternate location for a more representative sample will be upstream of weir wall, but this location will have challenge with accessing the pump and the sample piping will conflict with the use of bulkhead stop log. If the TRC analyzer is located inside the Sample Room, the sampling pipe will be approximately 250 feet long and at velocity 5 fps, the contact time within the sample pipe will be 50 seconds. This will be a few seconds over the 120 second contact time target after the application point. **Table 4-5** summarizes the estimated contact time from the sodium hypochlorite application point for different flow conditions. **Figure 4-18** shows chlorine demand sampling system. Two TRC analyzers one duty and one redundant will be provided. Feasibility of locating both TRC analyzers inside the Sample Room will be further evaluated in the Basis of Design phase.

Table 4-5 Estimated Contact Time for Chlorine Demand TRC Sample Location at Effluent Channel for Different Flow Conditions

Flow Conditions	Flow, Cfs/MGD	Estimated Contact Time to Sample Location, seconds	Estimated Contact Time in the Sampling Pipe (250 feet long pipe at 5 fps velocity), seconds	Estimated Contact Time at Analyzer Location, seconds
Minimum Flow	50/32	73	50	123
Avg Flow – Existing Collection System	118/76	36	50	86
Avg Flow – Future Collection System Configuration	380/245	17	50	67
Peak Flow - Existing Collection System	520/335	17	50	67
Peak Flow – Future Collection System Configuration	950/613	14	50	64

Note 1. Contact time in the effluent channel is function of the water depth at respective flow. The water depth increases with the flow.

PLAN

SECTION

Figure 4-18
 Leib Chlorine Demand Sampling System

Chlorine Decay Sampling System

To determine the real-time chlorine decay, the TRC should be measured ideally during the first 15-30 minutes of contact time which will need sample to be collected in the sewer downstream of Leib Regulator Chamber. The estimated contact time at the existing effluent sampling location at the Outfall Structure for different flow conditions is presented in the **Table 4-6**.

Table 4-6 Estimated Contact Time for Chlorine Demand TRC Sample Location at Outfall Structure for Different Flow Conditions

Flow Conditions	Flow, Cfs/MGD	Estimated Contact Time at Outfall Structure, minutes
Minimum Flow	50/32	82
Avg Flow – Existing Collection System	118/76	43
Avg Flow – Future Collection System Configuration	380/245	23
Peak Flow - Existing Collection System	520/335	20
Peak Flow – Future Collection System Configuration	950/613	15

Note 1. TRC Analyzer location assumed at the Outfall Structure same as original effluent TRC analyzer for outfall.

Locating the remote TRC analyzer will have the same challenges as the original effluent sampling system and TRC analyzer at the Outfall Structure, like remote location operation and maintenance and requirement of continuous water supply for online TRC analyzer. There will be possibility of the TRC analyzer not being maintained and calibrated resulting in questionable TRC results. Also locating TRC analyzer further upstream on the sewer system will have similar challenges.

Instead of using online TRC analyzer to provide real time TRC, manual grab samples could be collected for manual TRC measurements. The samples could be collected to develop trends for seasonal variation and variation during storm with respect to the first flush and post first flush storm partitioning.

The sampling system functionality recommendations for Leib are summarized in the **Table 4-7**.

Table 4-7 Recommended Sampling System at Leib

Sampling System	Sample Location	Sample Collection System	Sampler Location	Parameters	Need
Influent Sampling System	Influent Channel	- Replace existing influent sample pump with similar type - Reuse existing sampling piping	Sample Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	Effluent Channel right after the end of facility	- One sample location. - Two sample pumps (one duty / one standby) located in the Effluent Channel	Sample Room in the Control Building	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System ¹	Outfall (if online analyzer selected)	Outfall (if online analyzer selected)	Outfall Sample Pit (if online analyzer selected)	TRC	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Continue using existing location	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

Note: 1. Online TRC analyzer not proposed for the Chlorine Decay Sampling due to the challenges with the remote location.

5.0 Alternatives Analysis

5.1 Disinfection Control

All four modes of controlling the chlorination system will be included in the control system, with each mode having benefits and drawbacks. The advantages and disadvantages for all four modes are presented in **Table 5-1**.

Table 5-1 Disinfection Control Modes Advantages / Disadvantages

Control Mode	Advantages	Disadvantages
Manual Control	- Less amount of automation as only related to the influent flow and chemical feed rate - Lower data requirement, no complex instrumentation - No complex/costly instruments involved	- Requires highest safety factor on chlorine dose, increasing chemical costs compared to other three operation modes - More manual operation and staff involvement
Flow Paced	- Meets the guiding principle: keep operations and system improvements simple to extent feasible. Specifically provide a system (or equipment within the system) that can be operated simply in manual mode when needed - Lowest data requirement, no complex instrumentation - No complex/costly instruments involved	- Requires higher safety factor on chlorine dose, increasing chemical costs compared to ICT dose paced with TRC analyzers and machine learning model modes - More manual operation and staff involvement
ICT Dose Paced with TRC Analyzers	- Meets the guiding principle: keep operations and system improvements simple to extent feasible. Specifically provide a system (or equipment within the system) that can be operated simply in manual mode when needed - Lowest data requirement, no complex instrumentation - No complex/costly instruments involved	- Higher capital investment in analyzers and SCADA integration - Dependent on operations and maintenance of analyzers
Machine Learning Dosing Model	- Least manual operation and staff involvement - A well-trained model would provide minimized dose safety factor lowering chemical costs - Continuous data collected by analyzers and incrementally improve dosing algorithm and potential to further optimize the disinfection process and reduce operator work - Can be implemented in phased approach taking advantage of valuable data collected during initial facility operations	- Higher capital investment in analyzers and SCADA integration - Dependent on operations and maintenance of analyzers - Problems with the analyzers and other sensors may not be known until the data is adequately analyzed

5.2 Analyzers

Use of online instruments in intermittent flow applications, like CSO treatment facilities, for process control is a challenge. However, a well-thought-out design and a diligent maintenance approach to both the sampling system and the analyzers can result in a system that provides reliable and accurate results. These challenges relate to providing a continuous flow stream for keeping the sensors wet, and routine calibration and maintenance to ensure the sensors have not fouled. GLWA presently utilizes on-line TRC analyzers on an intermittent flow stream at the WRRF to monitor the total chlorine residual in the RRO that is placed into service during wet weather events. The sampling system for the TRC analyzers was designed to use the process flow stream, RRO effluent, when the outfall was in-service, and potable water to continuously keep the sensors wet when the outfall was not in service during dry weather conditions. Automated valves on the sampling piping were initiated on the level within the outfall. Evoqua Micro 2000 units with SFC analyzer / controller were installed for monitoring total residual chlorine upstream and downstream of the chemical injection points. GLWA performs routine maintenance on the analyzers as the TRC outputs are utilized by the control system for trimming the chemical feed rates. One important differentiator between the RRO sampling system and the design of a similar system for the CSO facilities is the flow stream composition. The RRO flow stream consists of mainly secondary effluent. During Workshop No. 3 (TM Set 2A) on May 12, 2023, GLWA described the colorimetric analyzer testing at Hubbell-Southfield facility. During workshop it was determined to use the colorimetric TRC analyzer manufactured by the SWAN Analytical Instruments. SWAN's initial model recommendation is AMI Codes-II TC which they have installed at multiple CSO application in Michigan.

On-line instrumentation is preferred for this application as it provides inputs to the Ovation DCS for adjustment of the chemical feed rates, viewing of real-time data from the Ovation operator workstations, historical data collection from the Ovation historian, and provides the data necessary for the ML model. However, on-line instrumentation will result in a higher level of maintenance on the system. **Table 5-2** summarizes the advantages and disadvantages of the on-line sensors. Manual (handheld) analyzers were not included as these devices offer far less maintenance, but do not provide any remote monitoring or integration with the control strategy.

Table 5-2. Total Residual Chlorine Analyzers Advantages / Disadvantages

Analyzer Type	Advantages	Disadvantages
Amperometric	- Wide measuring range - Integrated into Ovation DCS for viewing on operator workstations and historical data collection	- Need continuous flow for keeping sensor wet which will require automated valves and potable water source at times facility is not in service - Measurement dependent upon pH, may require separate pH sensor - Fouling concern with CSO flow stream - Additional instrument for GLWA to maintain - Routine maintenance and calibration requirement for analyzers as well electrolyte and membranes
Colorimetric	- Measurement independent of pH, temperature - Integrated into Ovation DCS for viewing on operator workstations and historical data collection - Recommended by HACH for CSO applications	- Need continuous flow for keeping sensor wet which will require automated valves and potable water source at times facility is not in service - Requires use of reagents and frequent replacement is required - Fouling concern with CSO flow stream - Additional instrument for GLWA to maintain

6.0 Life Cycle Cost Analysis

Not used.

7.0 Summary, Recommendations and Key Decisions

The recommendations for the disinfection control functionality, analyzer type, and sampling system functionality are presented in this section. Greater detail is provided in the preceding sections.

7.1 Disinfection Control Functionality

In addition to providing manual control, the following three means of optimizing and controlling the chlorine disinfection process are recommended:

- Flow paced
- ICT dose paced with TRC analyzer
- ML dosing model

7.1.1 Flow Paced

In the flow paced mode the operators will select the chlorine dose, input the stored sodium hypochlorite trade percent by weight and the control system will automatically adjust the sodium hypochlorite feed rate based on the influent flow to the CSO facility.

7.1.2 ICT Dose Paced with TRC Analyzer

Integrated CT dose paced with TRC analyzers is similar to flow paced using ICT value and continuous feedback of TRC concentration data to optimize sodium hypochlorite dose. The ICT dose pacing factors in more variables by incorporating the hydraulic efficiency of a contact volume as well as the chlorine demand and decay rates in the control algorithm. Two TRC analyzers are recommended, one shortly after chlorine addition, and the second further down the contact volume. The first TRC analyzer will allow for the chlorine demand to be determined, while the second TRC analyzer will allow for the chlorine decay to be determined. These inputs into the ICT model will allow for real-time adjustment to the chlorine dose based upon the changing water quality and contact times observed during storm events. In-lieu of using online TRC analyzers, operator can elect to enter chlorine demand and chlorine decay value based on bench-scale chlorine dose response testing performed periodically to capture the seasonal variation typically observed in CSO collection system.

7.1.3 Machine Learning Dosing Model

ML is a branch of computer science field dedicated to developing and implementing algorithms that allow computers to learn without being explicitly programmed to provide predictions and pattern recognition. The ML model predict changes in the present chlorine demand using the historical chlorine dosage, collected during a year of operation, TRC, and upstream water characteristics such as organic load, precipitation data, radar imagery, flow information, and date-time information. Because chlorine decay is typically quite small, the focus will be on chlorine demand which changes significantly based upon the influent water quality. The recommendation is to study and develop alternatives to delineate the design process to evaluate the feasibility of incorporating modification of the ICT approach and the potential for a ML to optimize system operation across multiple flows and bacterial loading scenarios. The recommendation is to train the model to optimize disinfectant usage by learning from historical system performance after 1 year of operation post upgrades. The investigation will identify which correlations between data from influent water quality online analyzers and disinfection performance to determine if the chlorine dose can be optimized in a broader range of conditions. If more data is collected after the first year of operation, a ML model could be continuously retrained to improve its accuracy over time. The recommendation is to have a discussion with the GLWA about the group of staff to be involved in the ML aspect of the project and the associated testing and research and development group could be more suitable for this task.

7.2 Analyzer Type

The recommendation is to provide on-line TRC analyzers to measure the real-time TRC concentrations at both facilities. The analyzers will provide inputs to the Ovation DCS for adjustment of the chemical feed rates, viewing of real-time data from the Ovation operator workstations, historical data collection from the Ovation historian, and provides the data necessary for the ML dosing model. Use of online analyzers in intermittent flow applications, like CSO treatment facilities is a challenge. However, providing a continuous flow stream for keeping the sensors wet and providing routine maintenance help mitigate these challenges. GLWA presently

utilizes on-line TRC analyzers on an intermittent flow stream at the WRRF to monitor the TRC in the Rouge River Outfall (RRO) that is placed into service during wet weather events through an automated system of motorized valves and a secondary water source. The colorimetric TRC analyzer is recommended based on the discussions with analyzer manufacturers and GLWA staff. Specifically the SWAN AMI Codes-II TC TRC analyzer will be utilized on the project. The analyzer design may include a small filtration system built in before the analyzer to handle solids and a flowmeter to ensure flow is delivered to the analyzer both when the CSO facility is in use and when the secondary water system is called to operate for providing a continuous flow to the analyzer.

7.3 Sampling System Functionality

The automatic/online sampling is required to implement on-line analyzers to measure parameters in real time. The sampling system functionality recommendations are summarized in the **Table 7-1** for Oakwood and **Table 7-2** for Leib.

Table 7-1 Recommended Sampling System at Oakwood

Sampling System	Sample Location	Sample Collection System	Sampler /Analyzer Location	Parameters	Need
Influent Sampling System	Influent East and West Wet Wells	- Replace existing influent sample pumps with similar type - Reuse existing sampling piping	Influent Sampling Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	At Screen Inlet Chamber upstream of screens	- Six sample locations between pump discharge standpipes and screen inlets. - Three submersible sample pumps in Screen Inlet Chamber	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System	One sample location at each CSO basin before effluent weir	One sample pump at each CSO Basin	Outside of Screen Room on Screen Inlet Chamber Roof Or Mechanical Room of Screen Facility (feasibility of location to be further evaluated in the Basis of Design)	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Effluent channel	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

Table 7-2 Recommended Sampling System at Leib

Sampling System	Sample Location	Sample Collection System	Sampler Location	Parameters	Need
Influent Sampling System	Influent Channel	- Replace existing influent sample pump with similar type - Reuse existing sampling piping	Sample Room in the Control Building	- TSS (Sensor) - COD (REDOX Titration after oxidation by potassium dichromate) - Turbidity (Sensor) - Temp/pH (Sensor) - TOC (Infrared) - UVA (UV absorption) - Bacteria Indication (ColiMinder™) (To be evaluated)	Machine learning model training
Chlorine Demand Sampling System	Effluent Channel right after the end of facility	- One sample location. - Two sample pumps (one duty / one standby) located in the Effluent Channel	Sample Room in the Control Building	TRC (Colorimetric by the SWAN Analytical Instruments)	To determine chlorine demand and provide feedback to the DCS.
Chlorine Decay Sampling System ¹	Outfall (if online analyzer needed)	Outfall (if online analyzer needed)	Outfall Sample Pit (if online analyzer needed)	TRC	To determine chlorine decay and provide feedback to the DCS.
Effluent Sampling System	Continue using existing location	Continue using existing system	Effluent Sample Room	Parameters required for NPDES permit compliance or monitoring	NPDES permit compliance or monitoring

Note: 1. Online TRC analyzer not proposed for the Chlorine Decay Sampling due to the challenges with the remote location.

7.3 Key Decisions

- Use colorimetric TRC analyzers and SWAN as the manufacturer.
- Agreement with means of controlling and optimizing the chlorine disinfection process: Manual Control, Flow Paced, ICT Dose Paced with TRC Analyzers, and Machine Learning (ML) Dosing model.
- Chlorine demand sampling location at Oakwood will be at Screen Inlet Chamber and chlorine decay sampling location at Oakwood will be in the CSO basin. TRC analyzer locations for chlorine demand and chlorine decay at Oakwood at Screen Facility will be potentially on the roof of Screen Inlet Chamber or Mechanical Room of Screen Facility feasibility of location will be evaluated during Basis of Design.

- Chlorine demand sampling location Leib will be in the Effluent Channel. Leib will not have online TRC analyzer for chlorine decay.
- Redundant TRC analyzers will be provided.
- Redundant sample pump with self-spares will be provided.

8.0 Next Steps

The items which require advancement/further development as the design process advances include the following:

8.1 Disinfection Control Functionality

8.1.1 Machine Learning Dosing Model

- The next steps in the development of ML model are laid out in the subsection 4.1.4.3 ML Workflow and 4.1.4.4 Project Work Plan.
- For ML model implementation using Edge computing, have meeting with GLWA PACS team to discuss security related considerations for the Edge computer and integrating data from external weather sources and new on-line analyzers into the Ovation system.

8.2 Analyzers

- Contact other analyzer manufacturers: ChemScan, Inc.
- Contact Vienna Water Monitoring Solutions for ColiMinder™ to investigate the adaption of technology for intermittent CSO application.

8.3 Sampling System Functionality

- Further evaluate the sampling location, sampling pumping and piping system and location of analyzers for the chlorine demand sampling system and chlorine decay sampling system for Oakwood and Leib.
 - Evaluate the feasibility of locating chlorine demand and chlorine decay TRC analyzers at Oakwood inside the Mechanical Room of the Screen Facility with respect to the available space and implication on the hazard classification.
 - Evaluate the location of influent water quality analyzers and chlorine demand TRC analyzers in the Leib sample room.
 - Review the Oakwood CFD model of the CSO basin to help determine a representative elevation and distance from the basin wall for the chlorine decay sample point.
- Develop the necessary water supply system for the continuous operation of analyzers and switching to the CSO sampling during the storm event.

Technical Memorandum

Scott Worth, PMA*

*From: Brian Hilts, CDMS
Brian Zuidervliet, CDMS
Arun Mande, CDMS
Mohamad Baydoun, CDMS*

Date: June 1, 2023

*Subject: TM-20: Chlorine System Alternatives
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The Great Lakes Water Authority (GLWA) retained the services of CDM Smith to evaluate and improve the existing disinfection systems at the Oakwood Combined Sewer Overflow (CSO) Retention and Treatment Basin (Oakwood) and Leib Screening and Disinfection Facility (Leib). The evaluation primarily included:

- Reviewing historic data associated with disinfection systems at both Oakwood and Leib.
- Bench top chlorine dose response analysis using wet weather samples from both facilities in 2022 and 2023 to determine the integrated contact time (ICT) value necessary to achieve the bacteria log inactivation to meet the permit requirements (discussed in TM-18).
- Modeling of the average (6-month, 24-hour storm) and peak (10-year, 24-hour storm) design storms for current and future collection system configurations to quantify storm and first flush volumes.
- Application of the ICT method (area under the dose response curve) to establish sodium hypochlorite storage requirements based upon the design storm and first flush volumes, and develop alternative feed system configurations.

The guiding principles for the GLWA CSO Improvement Project informed the sodium hypochlorite storage and feed system analysis and overall approach to the evaluation with an emphasis on operations and maintenance (O&M) improvements for the chemical storage and feed system. GLWA personnel indicated that the existing chemical feed systems at Oakwood and Leib are unreliable, expensive to maintain, and/or approaching the end of its useful life and need to be replaced.

The key findings from this evaluation are:

- Future collection system modifications (interconnections) will increase storm volumes considerably in comparison to the original basis of design (BOD) at both facilities. The peak design storm volume is anticipated to increase approximately 375% at Oakwood and 63% at Leib, which is the primary catalyst to the increase in sodium hypochlorite storage capacity.
- The existing sodium hypochlorite storage (two, 11,500-gallon tanks) at Oakwood is sufficient to treat two average design storms but will need to be replaced with larger tanks (two, 15,000-gallon tanks) once the proposed collection system interconnection is completed.
 - Computational Fluid Dynamic (CFD) analysis indicated that baffles could be installed in the existing basins to improve the hydraulic efficiency (i.e., baffling factor) associated with the basins, which could reduce storage requirements under the peak design storm condition by approximately 3,000 gallons. The baffles would not provide enough storage savings to avoid the need for new chemical storage tanks.
 - The sodium hypochlorite concentration would need to remain above the historic median concentration, 10.5% (trade percent by weight) to meet the storage requirements associated with the future collection system peak design storm. This may result in more frequent dumping and replenishing of sodium hypochlorite.
- The existing sodium hypochlorite storage (two, 10,450-gallon tanks) at Leib is sufficient to treat two average design storms but will need to be replaced with larger tanks (two, 12,600-gallon tanks) in anticipation of the proposed collection system interconnection is completed.
 - The sodium hypochlorite concentration would need to remain above 10.0% (trade percent by weight) to meet the storage requirements associated with the future collection system peak design storm. For reference, the historic median sodium hypochlorite concentration after dilution was 7.5% (trade percent by weight) between 2005 and 2022. This may result in more frequent dumping and replenishing of sodium hypochlorite.
- Recommend replacing the existing gear pumps at Oakwood and diaphragm (low-rate) and centrifugal pumps (high-rate) at Leib with redundant recirculation loops with centrifugal pumps and dedicated flow control valves for each sodium hypochlorite application point. This proposed chemical feed system will provide a more reliable and simple chemical feed system without compromising redundancy.

1.0 Introduction and Purpose

GLWA constructed the Oakwood and Leib facilities to meet National Pollution Discharge Elimination Program (NPDES) permit requirements. Oakwood was constructed in 2006 and Leib was constructed in 2002. The facilities remove screenings and disinfect combined sewer flows,

while Oakwood also provides flow retention. Both facilities utilize sodium hypochlorite to meet disinfection requirements.

The purpose of this technical memorandum is to document the results of the disinfection system evaluation, including;

- Overview of existing systems, original basis of design, regulatory requirements
- Evaluation of the existing system, summary of historic flow data and anticipated future flows, alternative sodium hypochlorite storage and feed solutions

1.1 Approach

Generally, the approach to the Oakwood and Leib disinfection system evaluation included:

- Chlorine dose response sampling for storm events in 2022 and 2023, including:
 - Oakwood October 31, 2022
 - Oakwood November 27, 2022
 - Oakwood February 27, 2023
 - Leib November 27, 2022
 - Leib January 19, 2023
 - Leib February 27, 2023
- Established the ICT and demand/decay at each facility based on the sampling results to establish a required dose (documented in TM-18)
- Applied the “high ICT” to the “first flush” volume to represent the challenging water quality conditions experienced in the “first flush” (i.e. higher chlorine demand and decay, higher bacteria concentration, etc.) and the “average ICT” to the remainder of the design storm volume to represent less challenging water quality conditions (i.e. lower chlorine demand and decay, lower bacteria concentration, etc.)
 - High ICT = observed ICT value required to achieve the inactivation goal to reduce maximum measured fecal coliform value down to half of the recreational seasonal bacteria limit (200 CFU/100 mL)
 - Average ICT = observed ICT value required to achieve inactivation goal to reduce the average undisinfected fecal coliform down to half of the recreational seasonal bacteria limit (200 CFU/100 mL)

- First Flush = initial volume of CSO overflow where the highest concentrations of contaminants and bacteria counts are observed because the ratio of wastewater to stormwater is relatively high. As the storm progresses, the ratio of wastewater to stormwater decreases, the wastewater is diluted, and the concentration of contaminants and bacteria counts are relatively low in comparison to the first flush.
- Used the required chlorine dose to establish sodium hypochlorite storage and feed requirements based on current and future design storms volumes and flows
- Based on the results, evaluated sodium hypochlorite storage and feed equipment alternatives, and made recommendations based on the guiding principles and technical feasibility of each alternative

The volume of the design storms attributed to the first flush was established based on information from the *2020 Wastewater Master Plan* where the first flush was simulated by using *E. coli* concentration curves input into Hydrological Simulation Program-Fortran (HSPF) and Storm Water Management Model (SWMM) models and grab samples to validate the model results. The models used influent water quality data from the Hubbell-Southfield, Conner Creek, Dearborn Height, and Inkster CSO facilities. The following key findings were used as the basis for establishing the first flush design storm volume:

- For smaller storms (i.e., 6-month, 24-hour) the first flush can be characterized as the first 20% of the overflow volume.
- For larger storms (i.e., 10-year, 24-hour) the first flush can be characterized as the first ¾-inches of rainfall.

The estimated first flush volumes are presented and discussed in Section 3.2.

1.1.1 Sodium Hypochlorite Storage Sizing

The approach to sizing the disinfection storage systems at Oakwood and Leib were discussed with GLWA. A summary of the discussion is included in Appendix A. **Table 1-1** shows the design storms that were used to size the sodium hypochlorite storage tanks at Leib and Oakwood.

Table 1-1 Design Storms for Sodium Hypochlorite Storage Sizing

Condition	Leib	Oakwood
Average	6-month, 24-hour storm	6-month, 24-hour storm
Peak	10-year, 24-hour storm	10-year, 24-hour storm

The chlorine dose required was calculated using Equation 1.

Equation 1

$$C_o = \frac{ICT}{C_T} + D$$

Where,

C_o = chlorine dose required (mg/L)

C_t = the effective contact time (theoretical contact time x baffling factor) (mins)

ICT = integrated CT (mg-min/L)

D = sodium hypochlorite demand and decay (mg/L) (from chlorine dose response sampling)

The required chemical storage was based on:

- The average and peak design storm volume.
- An average chlorine dose determined using the ICT value.
- A safety factor (i.e., two for average design storm events, and one for the peak design storm).
- Sodium hypochlorite concentration of:
 - 10.5% (trade percent by weight) at Oakwood, which is the historic median concentration.
 - 10% (trade percent by weight) at Leib, which is higher than the historic median concentration of 7.5% (trade percent by weight after dilution, see discussion in Section 3.3).

Sodium hypochlorite concentrations presented herein are trade percent by weight regardless of whether this is explicitly stated in the text, figure, or table.

1.1.2 Sodium Hypochlorite Chemical Feed Sizing and Configuration

The chemical feed system sizing was evaluated using:

- The applied chlorine dose established through the chlorine dose response testing (documented in TM-18)
- The baffling factor determined through computational fluid dynamics (CFD) modeling (Appendix B)
- Calculated disinfection contact volume
- Design flows

The design flows for each facility are shown in **Table 1-2**. Flow data is based on currently available and future predicted rainfall and sewerage flow data.

Table 1-2 Design Flows for Oakwood and Leib

Design Flow	Units	Oakwood	Leib	Reference
Min Flow	cfs/mgd	99/64	5/3	Leib – min. historic flow Oakwood – min. storm pump flow
Avg Flow – Current Collection System Configuration ¹	cfs/mgd	135/87	118/76	6-month, 24hr
Avg Flow – Future Collection System Configuration ¹	cfs/mgd	531/343	380/245	6-month, 24hr
Peak Flow – Current Collection System Configuration ¹	cfs/mgd	765/494	520/335	10yr, 24hr
Peak Flow – Future Collection System Configuration ¹	cfs/mgd	1,231/794	950/613	10yr, 24hr Leib – max. disinfection flow, 1 basin in operation Oakwood – max. disinfection flow
Design Peak Flow	cfs/mgd	1,660/1,071	2,000/1,290	Leib – max. hydraulic flow, flow does not bypass mixing chambers, 950 cfs/613 mgd disinfected Oakwood – max. hydraulic flow, 2 basins in operation, 1,231 cfs/794 mgd disinfected

¹ Predicted 5-minute peak flow rate

Oakwood has a maximum hydraulic peak flow capacity of 1,660 cfs (1,071 mgd) and maximum disinfection flow capacity of 1,231 cfs (794 mgd). Two CSO basins are used at flows greater than 1,231 cfs (794 mgd), which is an abnormal high flow condition. Leib has a maximum hydraulic peak flow capacity of 2,000 cfs (1,290 mgd) and maximum disinfection flow capacity of 950 cfs (613 mgd). At flows greater than 950 cfs (613 mgd), the gates to North Interceptor-East Arm (NIEA) are closed and excess flows continue through facility (i.e., not bypassed) and 950 cfs (613 mgd) is disinfected. This is an emergency, high flow condition. At the design peak flow condition (hydraulic maximum), the required chlorine dose was calculated using the effective contact time for the peak flow condition and the required sodium hypochlorite feed rate was based on the peak flow – future collection system configuration as this represents the maximum disinfected flow at both facilities. **Table 1-3** shows the design storm volumes that were used to establish the sodium hypochlorite storage and feed equipment sizing.

Table 1-3 Design Storm Volumes for Oakwood and Leib

Design Storm	Units	Oakwood	Leib	Reference
Avg Storm - Current Collection System Configuration	MG	17	21	6-month, 24hr
Avg Storm - Future Collection System Configuration	MG	92	54	6-month, 24hr
Peak Storm - Current Collection System Configuration	MG	81	185	10yr, 24hr
Peak Storm - Future Collection System Configuration	MG	368	367	10yr, 24hr

1.1.3 Guiding Principles

The guiding principles were developed in collaboration with GLWA for the CSO Improvements Project. The guiding principles provided guidelines for conducting evaluations, identified general areas for improvement, and defined overarching outcomes for the project. **Figure 1-1** summarizes the guiding principles that governed the approach to the disinfection systems evaluation and informed key decisions.

Equipment

- Do not replace equipment in kind – improve equipment
- Provide operational flexibility, cost savings (lifecycle cost basis) including current operational costs
- Reduce human capital and maintenance
- Provide equipment which is accessible and easy to maintain
- Equipment selection to accommodate intermittent use

O&M/System Considerations

- Process must operate reliably “on demand” (intermittent use)
- Keep operations and system improvements simple to extent feasible. Specifically provide a system (or equipment within the system) that can be operated simply in manual mode when needed
- Minimize single points of failure
- Provide sufficient redundancy for each equipment system (balance with reduced O&M)
- Maintain operation of Oakwood and Leib throughout construction phase

Collaboration

- Involve O&M staff in design development process, listen to them and effectively communicate with them
- Design with consistency in materials of construction across disciplines in each room/area

General

- Use same facility, area and room name by all disciplines

Figure 1-1
Summary of Guiding Principles

2.0 Existing System(s) Description (and/or Conditions)

The following subsections describe the existing CSO systems at Oakwood and Leib and design criteria for the respective sodium hypochlorite storage and feed systems.

2.1 Oakwood

Oakwood consists of the following major components:

- Two 18-foot inlet conduits
- Expansion zone with influent sample points
- East and west storm wet well with eight storm pumps and associated storm discharge standpipes
 - Two small variable frequency drive (VFD) storm pumps (P1 and P2)
 - Two large VFD storm pumps (P5 and P6)
 - Four large constant speed pumps (P3, P4, P7, and P8)
- Odor Control unit
- East and West sanitary wet well with manually cleaned bar screens and four submersible solids handling pumps
- Screenings Channel with six perforated plate screens
- Influent channel
- East and West CSO Basins with oil/grease baffles
- Effluent launder
- Effluent channel and conduit to the Rouge River via the O'Brien drain

Figure 2-1 shows a process flow diagram with the major system components at Oakwood.

Figure 2-1
 Oakwood Process Flow Diagram

2.1.1 Basis of Design and Existing Design Criteria

The existing design criteria for Oakwood is shown in **Table 2-1**. Oakwood's maximum hydraulic capacity is 1,660 cfs (1,071 million gallons per day [mgd]) and 48.5 million gallons (MG), which is based on the 10-year, 1-hour storm event.

Table 2-1 Oakwood Design Criteria from Basis of Design Report

Parameter	Units	Value	Reference
Maximum Hydraulic Capacity	cfs/mgd	1,660/1,071	CS-1364 Oakwood CSO Control Facility and Pump Station Design Memorandum 11 – Disinfection System

¹trade percent by weight

2.1.2 Sodium Hypochlorite Storage and Feed Systems

The sodium hypochlorite storage and feed system consist of the following major components:

- Storage Tanks
- Small and Large Feed Pumps

- Recirculation Pumps
- Basket Strainers
- Injection Nozzles
- Isolation, flow control, and check valves
- Flow metering and pressure instrumentation
- Carrier Water System

Chemical tanker trucks deliver sodium hypochlorite to Oakwood and the sodium hypochlorite is stored in two 11,500-gallon fiberglass tanks. A total of ten (eight duty/two standby, comprised of small and large pumps) positive displacement, magnetic-drive gear pumps feed sodium hypochlorite to each of the storm pump discharge pipes using injection nozzles (six per storm pump discharge). Carrier water is added to the chemical feed piping to ensure adequate flow through the injection nozzles. The small feed pumps (three duty/one standby) deliver sodium hypochlorite to the small VFD storm pumps (P1 and P2), and the large feed pumps (six duty/one standby) deliver sodium hypochlorite to the large storm pumps (P3 through P8). Two recirculation pumps are used to mitigate stratification of sodium hypochlorite in the storage tanks. Two titanium basket strainers are located on each of the 8-inch chemical feed pump suction lines from each of the storage tanks to protect the feed pumps from debris. **Table 2-2** and **Table 2-3** summarizes the design criteria for the sodium hypochlorite storage and feed equipment at Oakwood.

2.1.3 Operation of System

Oakwood receives sanitary and storm flows. During dry weather events, flow pumped from the sanitary wet well to the Northwest Interceptor (NWI) and treated at the Water Resource Recovery Facility (WRRF). During wet weather events when the flow exceeds the sanitary pump capacity (wet well level 73 feet):

- The storm pumps are placed in operation.
- Sanitary pumps are placed offline.
- Sodium hypochlorite feed begins, (For the initial injection of sodium hypochlorite at the onset of the storm, operators often manually increase the chlorine dose to reduce the relatively high fecal bacteria count associated with the first flush of the storm event. Based on discussions with Oakwood facility staff, the chemical feed flowmeters are not accurate. Therefore, the chemical feed is typically not based on flow measurement, but rather based on the operator's experience and how much storm volume the facility is receiving.
- Stormwater is pumped to the perforated screens and CSO basins.
- Once the level in the basin exceeds 114 feet, treated stormwater is conveyed by gravity through two effluent conduits through the O'Brien Drain and then to Outfall 109 and discharged to the Rouge River.

The two storm wet wells and downstream CSO basins can be operated in first-flush (flow to one storm wet well) or flow-through mode (flow to both storm wet wells). Chemical feed pumps operate in tandem with storm pumps and come online and offline as storm pumps come online and offline. There are two standby chemical feed pumps. One standby pump serves as a backup to storm pump P1 and P2 and the other standby pump serves as a backup to storm pumps P3 to P8. Chemical feed pumps can be operated in the following control modes:

- Manual from local control panel

- Contact time (CT) Method – logic varies pump speed to achieve a chlorine dose setpoint (max dose = 12 mg/L) or CT (chlorine concentration x contact time, max CT = 125 mg-min/L and min CT = 100 mg-min/L))
- Total Suspended Solids (TSS) Method – logic calculates required dose based on influent TSS, sodium hypochlorite concentration, influent flow

2.1.4 Regulatory Requirements

GLWA's Long Term CSO Control Plan incorporated Oakwood into the 1997 National Pollutant Discharge Elimination System (NPDES) permit. At the time of this TM, the NPDES permit requirements include:

- Report event influent and effluent flows (mgd)
- Report flow-weighted composite sampling results for:
 - carbonaceous biochemical oxygen demand (mg/L)
 - total suspended solids (mg/L)
 - ammonia nitrogen (mg/L as N)
 - total phosphorus (mg/L as P)
- Report event average and maximum total residual chlorine (TRC) (mg/L)
 - Goal: event average of 1.5 mg/L
 - Goal: event instantaneous maximum of 2.0 mg/L November – April
 - Goal: event instantaneous maximum of 3.0 mg/L May – October
- Report monthly and event (daily during discharge) oil and grease concentration (mg/L) from monitoring point 109A
- Report event minimum and maximum pH (S.U.)
- Report event minimum dissolved oxygen (mg/L)
- For daily Discharge Monitoring Reports (DMRs), report the geometric mean of all fecal coliform samples taken during an event, provided three or more samples are collected. Sample every two hours for the first six hours and every four hours thereafter for the duration of the discharge.
 - Limit: Fecal Coliform must be <400 cts/mL for each event May 1 – October 31
 - Limit: Fecal Coliform must be <1,000 cts/mL for each event November 1 – April 30

For monthly DMRs, report the highest Fecal Coliform event averages the “Maximum” columns under “Quality and Concentration.” Fecal coliform is the only parameter with a regulatory limit. The NPDES permit stated goal of the program is to operate the CSO retention treatment basins and the CSO screening and disinfection facilities in a manner which will provide consistent, effective disinfection while minimizing the discharge of TRC. The permit includes goals to limit TRC with reporting requirements should TRC concentrations exceed the goals. The disinfection optimization evaluation was conducted to aid GLWA in meeting the regulatory limit for fecal coliform count and TRC minimization goals. The Oakwood Project Performance Certificate (i.e., TRC Minimization Assessments) was submitted to Michigan Department of Environment, Great Lakes, and Energy (EGLE) [formerly MDEQ] in 2013, which documented the facility’s performance during wet weather events as required in the facilities NPDES permits.

2.2 Leib

Leib consists of the following major components:

- Influent channel
 - Two Water Champ rapid mixing chemical induction units (CIUs)
- Four screen channels with 12 screens
 - Four Vertical ROMAG CSO Screens
 - Eight Horizontal COPA Raked Storm Screen
- Screen outlet channel
- Screen collection channel
- Facility bypass channel and gates
- Mixing chambers
 - Sixteen Water Champ rapid mixing CIUs, four in each of the four rapid mixing chambers
- Disinfection chamber
- Dry weather channel
- Effluent channel

GLWA is considering alternative mixing technologies to replace the existing Water Champ rapid mixing CIUs. GLWA staff indicated that the seals on the Water Champ mixers need to be replaced relatively often and the motor must be bumped monthly. This is discussed further in the Mixing Technology Evaluation completed under a separate cover as part of this project.

Figure 2-2 shows a process flow diagram with the major system components at Leib.

Figure 2-2
Leib Process Flow Diagram

2.2.1 Existing Design Criteria

The existing design criteria for Leib is shown in **Table 2-4**. Leib is designed to handle 1,550 cfs (peak design flow) and convey 2,000 cfs.

¹trade percent by weight

2.2.2 Sodium Hypochlorite Storage and Feed Systems

The sodium hypochlorite storage and feed system consist of the following major components:

- Storage Tanks
- Prechlorination Feed Pumps
- Low- and High-Rate Mixing Chamber Feed Pumps
- Basket Strainers
- Prechlorination and Mixing Chamber Rapid Mixing CIUs

- Isolation, flow control, and check valves
- Flow metering and pressure instrumentation

Chemical tanker trucks deliver sodium hypochlorite to Leib and the sodium hypochlorite is stored in two 10,450-gallon fiberglass tanks. Sodium hypochlorite can be added to the process flow in two locations using positive displacement, diaphragm feed pumps and CIUs: namely, the influent channel upstream of the screens (prechlorination) and the mixing chambers downstream of the screens. Sodium hypochlorite is only fed at the prechlorination location at the onset of a storm event or when the mixing chamber sodium hypochlorite addition location cannot meet the chlorine demand.

Two prechlorination feed pumps (duty/standby) deliver sodium hypochlorite to the co-current CIUs located in the influent channel and four low-rate mixing chamber feed pumps (three duty/one standby) or two high-rate mixing chamber feed pumps (duty/standby) deliver sodium hypochlorite to sixteen counter-current CIUs (four rapid mixers per mixing chamber with four mixing chambers).

Table 2-5 and **Table 2-6** summarizes the design criteria for the sodium hypochlorite storage and feed equipment at Leib.

Table 2-5 Leib Sodium Hypochlorite Storage and Feed Equipment

The Leib O&M manual indicates the tank volume is 10,450-gallons, while the tank nameplates indicate the tank volume is 13,611-gallons. Neither data source specified whether the listed volume was the working volume or nominal tank volume. To investigate this discrepancy, CDM Smith collected field measurements and used 3D laser scan survey data to measure the tank dimensions. The dimensions generally matched the dimensions shown in the record drawings. Based on these investigations, it appears the 10,450-gallons is the volume of the tank from the top of the pump suction nozzle to the top of the tank sidewall (i.e., tank volume excluding dead space below suction nozzle and dome top of tank). While the 13,611-gallons appears to be the volume of the tank including the volume in the dome at the top of the tank. It is not clear if this includes the dead space volume occupied by the level sensor mounted on top of the tank. During the CSO Facilities Improvements workshop, GLWA and CDM Smith agreed given the age of the tanks (~23-years) it would be prudent to replace the tanks regardless of the tank working volume (i.e., 10,450-gallons vs 13,611-gallons). For the purposes of this technical memorandum, the volume from the O&M manual (i.e., 10,450-gallons) was used as the working volume for the tank.

2.2.3 Operation of System

During a CSO event water begins to flow over the effluent weir in the effluent channel and the chemical feed pump and counter-current CIUs are turned on. The prechlorination CIUs are manually operated and used 1) when flow exceeds 50 cfs with the anticipation that flow will increase and start flowing to the screens (~118 cfs), and 2) when the sixteen CIUs in the downstream mixing chambers cannot meet the disinfection chlorine residual requirements. The gate to the Toward Interceptor conveys screenings flow to the Detroit River Interceptor during wet weather events. When the wet weather flows decrease to the point where water stops flowing over the effluent weir, the sodium hypochlorite feed system turns off. During dry weather flow is diverted from the influent channel to the Toward Interceptor.

2.2.4 Regulatory Requirements

GLWA's Long Term CSO Control Plan incorporated Leib into the 1997 National Pollutant Discharge Elimination System (NPDES) permit. At the time of this TM, the NPDES permit requirements include:

- Report event influent and effluent flows (mgd)
- Report flow-weighted composite sampling results for:
 - carbonaceous biochemical oxygen demand (mg/L)
 - total suspended solids (mg/L)
 - ammonia nitrogen (mg/L as N)
 - total phosphorus (mg/L as P)
- Report event average and maximum total residual chlorine (TRC) (mg/L)
 - Goal: event average of 2.0 mg/L November – April
 - Goal: event average of 3.0 mg/L May – October
- Report event minimum and maximum pH (S.U.)
- Report event minimum dissolved oxygen (mg/L)
- For daily DMRs, report the geometric mean of all fecal coliform samples taken during an event, provided three or more samples are collected. Sample every two hours for the first six hours and every four hours thereafter for the duration of the discharge.
 - Limit: Fecal Coliform must be <400 cts/mL for each event May 1 – October 31
 - Limit: Fecal Coliform must be <1,000 cts/mL for each event November 1 – April 30

- For monthly DMRs, report the highest Fecal Coliform event averages.

Fecal coliform is the only parameter with a regulatory limit. The NPDES permit includes goals to limit TRC with reporting requirements should TRC concentrations exceed the goals. The disinfection optimization evaluation was conducted to aid GLWA in meeting the regulatory limit for fecal coliform count and TRC minimization goals. A Total Residual Chlorine Minimization Assessment was submitted to EGLE for Baby Creek, Belle Isle, Conner Creek, St. Aubin, and Leib CSO facilities in 2012 (i.e., TRC Minimization Assessments), which documented the facility's performance during wet weather events as required in the facilities NPDES permits.

3.0 System Evaluation

This section summarizes the review of historic data associated with both CSO treatment facilities, presents the anticipated future collection system configurations, and discusses the design criteria for the storage and feed systems.

3.1 Review of Historic Data

3.1.1 CSO Events Flows and Duration

The Design team reviewed the CSO events reported EGLE for a three-year period of 2019-2021 for the Oakwood and Leib facilities. The CSO events reported to EGLE are events where combined sewer flow was discharged from the facility to an outfall structure. The findings from that review are discussed below.

3.1.1.1 Oakwood

Table 3-1 summarizes the CSO events reported to the EGLE per year, maximum and average volumes discharged and duration for a single event for 2019-2021.

Table 3-1 Summary of CSO Events Reported to EGLE During 2019-2021

Parameters		Units	Oakwood Facility
Number of Reported Events	2019	No.	11
	2020	No.	11
	2021	No.	14
Maximum Volume Discharged in a Single Event		MG	110.4
Average Volume Discharged in a Single Event		MG	26.6
Maximum Duration of a Single Event		Hrs	223.5
Average Duration of a Single Event		Hrs	34.3

Between 2019 and 2021, there were 36 storm events at Oakwood where combined sewer flows were discharged to the outfall. Based on the DMRs from 2019 to 2022, there was a total of 79 storm events that were treated at Oakwood; however, only 36 of the events resulted in an outfall discharge and were subsequently reported to EGLE. The remaining 43 storm events from the DMRs

were events where combined sewer flows were treated (disinfection and screening) at Oakwood and diverted to the WRRF as flows allowed, which prevented the need to discharge at the outfall. The duration and volume for the 36 CSO outfall discharge events at Oakwood are shown in **Figure 3-1** and **Figure 3-2**.

Figure 3-1
Oakwood CSO Volumes Reported to EGLE in 2019-2021

Figure 3-2
Oakwood CSO Event Durations Reported to EGLE in 2019-2021

3.1.1.2 Leib

Table 3-2 summarizes the CSO events reported to the EGLE per year, maximum and average volumes discharged and duration for a single event for 2019-2021.

Table 3-2 Summary of CSO Events Reported to EGLE During 2019-2021

Parameters		Units	Leib Facility

Figure 3-4
Leib CSO Event Durations Reported to EGLE in 2019-2021

3.1.2 Historic Sodium Hypochlorite Concentration

Historically, sodium hypochlorite delivered at both facilities has a concentration of 12% (trade percent by weight). GLWA staff measure the concentration of sodium hypochlorite as delivered and

periodically in each storage tank to verify the concentration delivered. GLWA standard operating procedure has staff discard sodium hypochlorite when the concentration drops below 5%. Measuring the sodium hypochlorite concentration allows GLWA staff to better manage the chemical inventory, and to determine how many pounds of chlorine are being added depending upon the sodium hypochlorite concentration and flow rate to the application points. The concentration of sodium hypochlorite at Oakwood from 2012 to 2022 and at Leib from 2005 to 2022 is shown in **Figure 3-5**.

Figure 3-5
Historic Sodium Hypochlorite Concentration as Delivered at Oakwood and Leib

The 75th percentile of the as delivered sodium hypochlorite concentration at both facilities is roughly 13% (trade percent by weight) as chlorine, which represents the maximum sodium hypochlorite concentration at Oakwood and Leib. The outliers shown in **Figure 3-5** are likely a function of sampling and testing errors or anomalies rather than poor product quality, particularly for the low concentrations reported (i.e., 2-3% trade percent by weight at Oakwood and 5% trade percent by weight at Leib). The historic sodium hypochlorite concentrations in each chemical storage tank are shown in **Figure 3-6**. The concentration decreases from the maximum concentration as delivered (~13% trade percent by weight) because the sodium hypochlorite degrades over time. The sodium hypochlorite is replenished after storm events or in coordination

with routine dumping procedures to restore the sodium hypochlorite concentration after prolonged dry weather periods and in anticipation of storm events.

Figure 3-6
Historic Sodium Hypochlorite Concentration as Stored at Oakwood and Leib

The concentration in the chemical storage tanks at Oakwood and Leib generally vary between 11% and 7%, and 8% and 5% (trade percent by weight), respectively. This generally matches the Standard Operating Procedures (SOPs) for both facilities. The concentrations lower than 7% at Oakwood and 5% (trade percent by weight) at Leib (i.e., ~2% trade percent by weight) can be attributed to prolong periods of dry weather.

3.1.3 Historic Sodium Hypochlorite Dose and Usage

In order to calculate the approximate historic chlorine dose (mg/L), The Design Team reviewed:

- 2020 and 2021 historic storm event flow data from GLWA's SCADA system
 - During this evaluation it was identified that Oakwood storm pump flow data may be unreliable; however, for the purposes of this technical memorandum and in the absence of more reliable data it was assumed the flow data was reasonably accurate.

- Where effluent data was available (i.e., events with flow discharged to outfall), effluent data was used in lieu of influent flow data. Where effluent data was not available (i.e., events where no flow was discharged to outfall and sodium hypochlorite was used), influent flow data was used. The majority of events included in this analysis were based on effluent flow data.
- Sodium hypochlorite storage tanks levels SCADA data
- Sodium hypochlorite concentration data from GLWA bleach report test results

At Oakwood, the historic chlorine dose evaluation was limited to

- Events with flows reported by EGLE, which include all outfall events
- Storm events with a volume greater than 4 MG and average flow greater than 50 cfs
 - Based on historic SCADA data analysis, it is assumed that decreases in tank levels without storm flows or when storm event volumes were less than 4 MG and the average flow is less than 50 cfs represent chemical purge events to restore the sodium hypochlorite concentration in alignment with SOPs. Prolonged decreases in tank levels were attributed to leaking drain valves and was also not included in the historic dose evaluation.

At Leib, the historic chlorine dose evaluation was limited to

- Events with flows reported by EGLE, which include all discharge events
- Events with an average flow greater than 50 cfs and peak flow greater than 100 cfs, which represents the conditions required to start sodium hypochlorite in anticipation of a discharge event.

The average historic sodium hypochlorite concentration during the evaluated storm events was 8.3% at Leib and 10.7% (trade percent by weight) at Oakwood. As shown in **Figure 3-7**, the average chlorine dose was 6.6 mg/L at Leib and 22.6 mg/L at Oakwood. The maximum chlorine dose at Leib and Oakwood was 19 mg/L and 85 mg/L, respectively. The calculated doses may be artificially high, particularly at Oakwood, because the existing storm pump flow meters may be missing reads or reporting artificially low flows resulting in artificially low values for volume disinfected. At Oakwood, the unreliable storm flow meters make flow pace dosing challenging and the operators tend to feed sodium hypochlorite manually at higher rates to make sure disinfection permit requirements are met. These statements are based on observations made during site visits during storm events and discussions with GLWA staff.

For example, during one ride-along event CDM Smith staff observed a flow measurement of approximately 30 cfs for Storm Pump 1. Using the factory test curve to approximate the flow rate at the observed field conditions results in an anticipated flow of approximately 47 cfs. The impeller to

wear area clearance may have changed since the factory test, which may be contributing to the differences in observed and anticipated flows. The extent of the metering challenges can be explored further through more detailed discussions with GLWA staff.

Based on the historical chlorine usage and the total storm volume treated, the chlorine used per unit storm volume was determined in lbs/MG and presented in **Figures 3-8** and **3-9**. To approximate the potential impact of flow measurement inaccuracies at Oakwood on the historic chlorine dose analysis, the ratio between the observed flow measurement and anticipated flow measurement from the factory pump test curve were extrapolated to the historic flows. The historical flows and modified historical flows were included in **Figure 3-8** for comparison. The chlorine dose in the modified historical flow evaluation, decreased by approximately 36% which is equivalent to the difference between the field observation and factory pump test curve anticipated flows.

Figure 3-9
 Calculated Historic Chlorine Used per Unit Storm Volume (lb/MG) at Leib

3.2 Anticipated Future Collection System Configuration Conditions

Modeling conducted by the Design Team evaluated existing collection system configuration design storm event flow conditions (flow, duration, and intensity), anticipated future collection system configuration storm event flow conditions, and the impact of the proposed Oakwood District Intercommunity Relief Sewer (ODIRS) at Oakwood and Meldrum Sewer connection at Leib. The evaluation included the 6-month, 24-hour storm event (average design storm event) and 10-year, 24-hour storm event (peak design storm event). **Figure 3-10** and **Figure 3-12** show the model results for the existing and future collection system configuration average design storm event at Oakwood and Leib, respectively. **Figure 3-11** and **Figure 3-13** show the model results for the existing and future collection system configuration peak design storm event at Oakwood and Leib, respectively.

Figure 3-10
Oakwood 6-month, 24-hour Storm Event with Existing and Future Collection System Configurations

Figure 3-11
Oakwood 10-year, 24-hour Storm Event with Existing and Future Collection System Configurations

Figure 3-12
Leib 6-month, 24-hour Storm Event with Existing and Future Collection System Configurations

Figure 3-13
Leib 10-year, 24-hour Storm Event with Existing and Future Collection System Configurations

The key findings from this evaluation as they relate to the assessment of the existing sodium hypochlorite storage and feed system are

- Increases in anticipated storm volume summarized in **Table 3-3**
- Longer periods of sustained flow after the tie-in of the proposed ODIRS

Table 3-3 Increase in Storm Volumes for Future Collection System Conditions for Oakwood and Leib

Design Storm	Current Collection System Conditions	Future Collection System Conditions	
	Total Treated Volume, MG	Total Treated Volume, MG	Total Treated Volume, % Increase
Oakwood			
6-month, 24-hours	16.5	92.3	460%
10-year, 24-hours	80.5	368.3	358%
Leib			
6-month, 24-hours	21.2	53.9	155%
10-year, 24-hours	185.4	366.6	98%

At Oakwood, it is unclear how relatively small storm events will behave in relation to minimum pump capacity. If the influent flow is less than the minimum pump capacity, this causes Oakwood to operate in a “draw fill” mode. Under this mode of operation, contact times can be relatively long as the CSO basins are filled intermittently with pumps turning on and off as the influent volume is drawn down. Conversely, when the influent flow is greater than the minimum pump capacity, the facility can operate in a more continuous mode.

The modeled design storm hydrographs were used to estimate the first flush volume for each design storm, which were used to calculate the required sodium hypochlorite storage capacity. The approach to establishing the first flush volume is included in Section 1.1 The estimated first flush volumes are included in **Table 3-4**.

Table 3-4 Estimated First Flush Volumes for Oakwood and Leib

Design Flow	Units	Oakwood	Leib	Reference
Avg Storm – Current Collection System	MG (% of design storm volume)	4 (20%)	4 (20%)	6-month, 24hr
Avg Storm - Future Collection System	MG (% of design storm volume)	19 (20%)	11 (20%)	6-month, 24hr
Peak Storm - Current Collection System	MG (% of design storm volume)	12 (3%)	5 (15%)	10yr, 24hr
Peak Storm - Future Collection System	MG (% of design storm volume)	66 (10%)	37 (18%)	10yr, 24hr

3.3 Design Criteria

The design criteria for the proposed sodium hypochlorite storage and feed improvements were based on the following inputs and outputs.

Inputs:

- ICT values (See TM-18 for ICT value determination)
- Chlorine Demand and Decay (See TM-18 for values)
- Sodium Hypochlorite Concentration (based on historic bleach test results when chemical was used for treatment – excludes concentration data for routine dumping and when chemical was not being used).
 - Median concentration for Oakwood, which is 10.5% (trade percent by weight)
 - The median concentration for Leib is 7.5% (trade percent by weight after dilution); however, 10.0% (trade percent by weight) was used for chemical storage sizing to reduce storage requirements and allow proposed larger storage tanks to fit within existing chemical room (see detailed discussion Section 3.2.2.1 Leib Chemical Storage Evaluation)
- Baffling Factor
 - Established through CFD analysis at Oakwood
 - For the purposes of the technical memorandum, a representative baffling factor was assigned to the Leib facility based on the Chlorine Contact Chamber Design and Flow Evaluation worksheet v1.04 published by the California Department of Health Services (Appendix C). It is recognized that the California Department of Health Services does not have jurisdiction for GLWA; however, in the absence of similar guidance from Michigan/EGLE, tracer study data, or CFD study results this reference provides a basis for the evaluation.
- Contact Time
 - Calculated at the design flows and volume limitations (i.e., existing structures).
- Safety Factor
- Design Storm Volume
- Estimated First Flush Volume
- Design Storm Flow

Outputs

- Required Chlorine Dose (mg/L)
- Required Sodium Hypochlorite Storage (gallons)

- Required Sodium Hypochlorite Feed Flow (gpm)

The design criteria for Oakwood and Leib are presented in the following subsections. All sodium hypochlorite storage volumes presented herein are working storage volumes (does not include volume 6 in. below the top of the suction connection and 6 in. above the invert of overflow connection).

3.2.1 Oakwood

The required chlorine dose calculated at each design flow is shown in **Table 3-5**. The low, average, and high ICT values were established through dose response testing and discussed in TM-18. The high ICT is based on achieving inactivation goal of a maximum measured fecal coliform value down to half of the recreational seasonal bacteria limit (200 CFU/100 mL) and the average ICT is based on the average undisinfected fecal coliform down to half of the recreational seasonal bacteria limit (200 CFU/100 mL). The low ICT value represents a theoretical minimum required dose and was established by using the minimum demand and decay value from the dose response testing.

Table 3-5 Summary of Design Flows and Dose Requirements at Oakwood

¹baffling factor from CFD analysis for CSO basin baffle alternative

The TRC required is based on the existing effluent channel sample pump location. The TRC required for the current collection system average and minimum design storm flows are generally in alignment with the NPDES TRC operational goals (1.5 mg/L event average, 2.0 mg/L November – April and 3.0 mg/L May – October event instantaneous maximum). Under current collection system average flow conditions and with an average ICT, the TRC required at the end of the CSO basins meets the NPDES TRC operational goals. The required TRC increases as storm flows increase and the effective contact times decrease. The ICT values can be refined through additional testing, particularly during high flow events once the proposed ODIRS is constructed, which may reduce the TRC required.

The low ICT value will be used to define the minimum chemical feed requirements and equipment sizing. The low ICT value is not used for chemical storage sizing. The high and average ICT values represent the normal to high range in anticipated chemical dose requirements for appropriately sizing the chemical storage tanks.

The required chlorine doses were averaged for each design condition (high and average ICT) and these values were used as the basis for calculating the required sodium hypochlorite storage. The average required chlorine doses are shown in **Table 3-6**. Averaging the required doses (high and average ICT separately) represents a combination of the challenging water quality experienced during the first flush, less challenging water quality during high flows, and poor water quality at the tail of wet weather events when sewerage is less dilute with receding storm flows. This is also accounted for in assigning the higher demand and decay values from the sampling to the lower flows. The average maximum chlorine demand value of 4.0 mg/L (average of two maximum

chlorine demand values, 3.5 and 4.5 mg/L) was assigned to the current collection system minimum design storm (64 mgd) to account for the less dilute sewerage flows. Conversely, the minimum chlorine demand value of 1.6 mg/L was assigned to the future collection system max (794 mgd) and design peak storm flows (1,071 mgd) to account for the dilution of the sewerage flow with increased storm flows. The chlorine demand response data is included in TM-18.

Table 3-6 Average Required Chlorine Dose at Oakwood

Parameter	Units	No Baffles	Baffle Alternative	Dose Reduction (%)
High ICT	mg/L	14.0	12.3	12%
Avg ICT	mg/L	7.4	6.7	9.5%

3.2.1.1 Oakwood Storage Evaluation

The following design bases were evaluated to compare the required storage volumes. The original BOD and draw fill scenarios were included in the evaluation to compare the proposed design criteria with the original BOD and alternative mode of operation (non-continuous) design criteria and resulting sodium hypochlorite storage requirements.

- Original BOD– represents the original design criteria from CS-1364 *Oakwood CSO Control Facility and Pump Station Design Memorandum 11 – Disinfection System*. The design criteria were developed based on chlorine residual and bacteria sampling results at Puritan-Fenkell and Hubbell-Southfield CSO Detention Basins and Conner Creek Pilot CSO Control Facility CT test results.
- Average ICT – represents achieving inactivation goal to reduce average undisinfected fecal coliform to half of the recreational seasonal bacteria limit (200 CFU/100 mL), which results in a lower chlorine dose requirements than the High ICT condition.
- High ICT – represents achieving inactivation goal to reduce maximum measured fecal coliform value to half of the recreational seasonal bacteria limit (200 CFU/ 100 mL), which results in a higher chlorine dose requirements than the Average ICT condition.
- Draw Fill – represents low flow conditions where the influent flow is close to the minimum storm pump flow resulting in periodic cycling of the small storm pumps that draws down the wet well and portions of the upstream conduit. This mode of operation commonly occurs with relatively small storm events that do not produce enough volume to trigger an outfall event. This mode of operation results in indeterminately long contact times rather than a continuous flow mode.

To calculate the required sodium hypochlorite storage for the ICT method, the design storm volumes were partitioned into the first flush volume and remaining storm volume (i.e., post first flush volume). The high ICT dose was used to calculate the required storage associated with the first flush portion of the design storm volume and the average ICT dose was used to calculate the

required storage for the post first flush design storm volume. This approach accounts for the poor water quality experienced during the first flush and estimates the impacts on chemical storage requirements. The required sodium hypochlorite for the first flush, post first flush, and total design storm volume are shown in **Table 3-7**.

Table 3-7 Summary of Required Storage at Oakwood Under Various Design Conditions

Parameter ¹	Units	Current Collection System Conditions		Future Collection System Conditions

Figure 3-14 through **Figure 3-16**, show the required storage volume under the various design conditions in comparison to the existing storage volume and modified/expanded storage volumes. The red lines represent the existing storage volume (solid red line) and the available storage if the existing tanks were replaced with larger tanks with limited or no modification to the existing storage room (dotted red line). The modified/expanded storage volume (dotted red line) is only shown on the peak design storm graph as this condition dictates the chemical storage requirements (i.e., storage requirements for one peak design storm is greater than two average design storms). The storage alternatives may not be applicable to all design conditions but rather serve as a comparison to contextualize the required storage volume in comparison to the existing storage tanks.

Figure 3-14
Oakwood Design Storm Comparison

Figure 3-15
Oakwood Sodium Hypochlorite Storage Requirements for Current and Future Collection System Average Design Storm

Figure 3-16
Oakwood Sodium Hypochlorite Storage Requirements for Current and Future Collection System Peak Design Storm

The key takeaways from the storage evaluation are:

- The primary driver for the increase in required sodium hypochlorite storage is an increase in the projected future flow (see **Figure 3-14**) associated with the connection of the proposed ODIRS. For example, the original BOD had a peak design storm volume of 98 MG (7-day CSO max.) and the future collection system peak design storm volume for this evaluation is 368 MG (10-year, 24-hour storm), which is a 375% increase in volume.
- Average Design Storm (two events)
 - The existing chemical storage tanks provide sufficient storage to treat two current collection system average design storms with 5.0 to 13.0% (trade percent by weight) sodium hypochlorite concentration (see **Figure 3-15**).
 - If sodium hypochlorite concentration is greater than 5.0% (trade percent by weight), the existing chemical storage tanks provide sufficient storage to treat two future collection system average design storms (see **Figure 3-15**).
- Peak Design Storm (one event)
 - The storage requirements for a single peak design storm are greater than the storage requirements for two average design storm events; therefore, the single peak design storm dictates the maximum storage requirement.
 - There is sufficient storage to treat one current collection system peak design storm (5.0% to 13.0% trade percent by weight)
 - With 10.5 % (trade percent by weight) sodium hypochlorite, replacing the existing chemical storage tanks with two larger chemical storage tanks will provide enough chemical storage to meet the future collection system peak design storm demand (see **Figure 3-16**).
 - Installing baffles in the CSO basins could reduce the storage requirement by approximately 3,000 gallons; however, the existing storage tanks would still need to be replaced with larger tanks (see **Figure 3-16**).
 - The SOP should be updated when the ODIRS is connected to replenish sodium hypochlorite when the concentration is less than 10% (trade percent by weight) to meet future collection system storm event storage requirements.
- Additional undisinfected bacteria and chlorine demand sampling and testing will help further refine the high ICT and average ICT values.

The challenges associated with installing new larger sodium hypochlorite storage tanks at the existing facility are discussed in Section 4.

3.2.1.2 Oakwood Chemical Feed Evaluation

The sodium hypochlorite feed rate requirements were established based on the minimum and maximum feed requirements across the full range of design conditions (min flow to design peak flow, sodium hypochlorite concentration of 5% to 13% (trade percent by weight) and min to high ICT). The full facility sodium hypochlorite feed requirements are shown in **Table 3-9**.

- The minimum and maximum feed requirement at Oakwood are 0.4 gpm and 126.0 gpm, respectively. This represents a very large turndown ratio (315:1), which will need to be accounted for in the chemical feed alternatives.
 - Sizing of flow control valves and chemical feed recirculation pumps will be completed in the BOD phase based on system feed rate.
- Adding baffles would reduce the maximum feed requirements by approximately 15% (126.0 gpm no baffles to 107.1 gpm with baffles). Reductions in the minimum feed requirement would be negligible (~5%).
- Updating the SOP to replenish the sodium hypochlorite concentration when it falls below 10.5% and not allowing the sodium hypochlorite to reach 5% reduces the maximum feed rate by roughly half (264.7 gpm to 126.0 gpm)

Table 3-9 Summary of Total Sodium Flows Requirements at Oakwood

Parameter	Units	Current Collection System Average	Future Collection System Average

Avg ICT (50)							
TRC Required	mg/L	5.2	3.5	2.7	2.3	1.3	0.7
Chlorine Dose	mg/L	7.7	6.0	6.3	5.9	6.0	5.4
Low ICT (20)							
TRC Required	mg/L	2.1	1.4	1.1	0.9	0.5	0.3
Chlorine Dose	mg/L	3.3	2.6	2.3	2.1	1.7	1.5

¹Contact volume calculated using linear interpolation of model results for other flow conditions assuming sodium hypochlorite is added at prechlorination application points at 50 cfs in anticipation of storm event (based on GLWA staff feedback on facility operation).

The TRC required is based on the existing sampling station located at the outfall. The TRC required for the current collection system average and minimum design storm flows are generally in alignment with the NPDES TRC operational goals (1.5 mg/L event average, 2.0 mg/L November – April and 3.0 mg/L May – October event instantaneous maximum). Under current collection system average flow conditions and with an average ICT, the TRC required at the end of the CSO basins meets the NPDES TRC operational goals. The required TRC increases as storm flows increase and the effective contact times decrease. The ICT values can be refined through additional testing, particularly during high flow events once the proposed Meldrum connection is constructed, which may reduce the TRC required.

The low ICT value will be used to define the minimum chemical feed requirements and equipment sizing. The low ICT value is not used for chemical storage sizing. The high and average ICT values represent the normal to high range in anticipated chemical dose requirements for appropriately sizing the chemical storage tanks.

The average maximum chlorine demand value of 4.8 mg/L (average of maximum chlorine demand values, 3.0, 4.3, and 7.0 mg/L) was assigned to the current collection system minimum design storm (32 mgd) to account for the less dilute sewerage flows. Conversely, the minimum chlorine demand value of 2.5 mg/L (median of minimum chlorine demand values, 2.5, 2.5, and 1.9 mg/L) was assigned to the future collection system max (613 mgd) and design peak storm flows (1,290 mgd) to account for the dilution of the sewerage flow with increased storm flows. The chlorine demand response data is included in TM-18. Similar to the approach with Oakwood, the required chlorine doses were averaged for each design condition and these values were used as the basis for calculating the required sodium hypochlorite storage. The average required chlorine doses are shown in **Table 3-11**.

Table 3-11 Average Required Chlorine Dose at Leib

Parameter	Units	Required Chlorine Dose
High ICT	mg/L	11.1
Avg ICT	mg/L	6.3

3.2.2.1 Leib Chemical Storage Evaluation

The following design bases were evaluated to compare the required storage volumes. The original BOD and as-built scenarios were included in the evaluation to compare the proposed design criteria with the original BOD and as-built design criteria and resulting sodium hypochlorite storage requirements.

- Original BOD – represents the original design criteria from CS-1285 *Leib and St. Aubin Screening and Disinfection Facilities Basis of Design Report*, which was derived from chlorine dose response testing.
- As Built Condition – represents the as constructed design criteria which is different from the BOD. Specifically, the chlorine dose was 25 mg/L in the original BOD and was revised to 10 mg/L (as documented in the 2005 O&M manual) as a result of chlorine dose response testing completed after the BOD report but before the detailed design was completed. This reduced the required storage volume by about 250%.
- Average ICT – represents achieving inactivation goal to reduce average undisinfected fecal coliform to half of the recreational seasonal bacteria limit (200 CFU/100 mL), which results in a lower chlorine dose requirements than the High ICT condition.
- High ICT – represents achieving inactivation goal to reduce maximum measured fecal coliform value to half of the recreational seasonal bacteria limit (200 CFU/ 100 mL), which results in a higher chlorine dose requirements than the Average ICT condition.

The same approach to calculating the required sodium hypochlorite storage as Oakwood was applied to Leib (i.e., ICT method partitioning the first flush volume and post first flush volume). The

required sodium hypochlorite for the first flush, post first flush, and total design storm volume are shown in **Table 3-12**.

Table 3-12 Summary of Required Storage at Leib Under Various Design Conditions

Figure 3-17 through **Figure 3-19**, show the required storage volume under the various design conditions in comparison to the existing storage volume and modified/expanded storage volumes. The red lines represent the existing storage volume (solid red line) and the available storage if the existing tanks were replaced with larger tanks with limited or no modification to the existing storage room (dotted red line). The modified/expanded storage volume (dotted red line) is only shown on the peak design storm graph as this condition dictates the chemical storage requirements (i.e., storage requirements for one peak design storm is greater than two average design storms). The storage alternatives may not be applicable to all design conditions but rather serve as a comparison to contextualize the required storage volume in comparison to the existing storage tanks.

Figure 3-17
Leib Design Storm Comparison

Figure 3-18
Leib Sodium Hypochlorite Storage Requirements for Current and Future Collection System Average Design Storm

Figure 3-19
Leib Sodium Hypochlorite Storage Requirements for Current and Future Collection System Peak Design Storm

The key takeaways from the storage evaluation are:

- The primary driver for the increase in required sodium hypochlorite storage is an increase in the projected future collection system flow (see **Figure 3-17**). For example, the original BOD had a peak design storm volume of 225 MG (7-day CSO max.) and the future collection system peak design storm volume for this evaluation is 367 MG (10-year, 24-hour storm), which is a 63% increase in volume.
- Average Design Storm (two events)
 - The existing chemical storage tanks provide sufficient storage for two current or future collection system average design storms for all conditions evaluated (5.0 to 13.0% trade percent by weight) sodium hypochlorite by weight, see green bars in **Figure 3-18**.
- Peak Design Storm (one event)
 - The storage requirements for a single peak design storm are greater than the storage requirements for two average design storm events; therefore, the single peak design storm will dictate the maximum storage requirement.
 - There is sufficient storage to meet current collection system peak design storm demands down to nearly 5% (trade percent by weight) concentration (see blue bars in **Figure 3-19**).
 - There is not enough storage to meet future collection system peak design storm demands (see blue bars in **Figure 3-19**). At 10.0% (trade percent by weight), two new larger capacity storage tanks (~12,600-gallon tanks) would be required.
 - The SOP should be updated to replenish sodium hypochlorite when the concentration is less than 10% (trade percent by weight) to help meet future collection system storm event storage requirements.
- Additional undisinfected bacteria and chlorine demand sampling and testing will help further refine the high ICT and average ICT values.

The challenges associated with installing new larger sodium hypochlorite storage tanks at the existing facility are discussed in Section 4.

3.2.2.2 Leib Chemical Feed Evaluation

The sodium hypochlorite feed rate requirements were established based on the minimum and maximum feed requirements across the full range of design conditions (min flow to design peak flow, sodium hypochlorite concentration of 5% to 13% (trade percent by weight) and min to high ICT). The full facility sodium hypochlorite feed rate requirements are shown in **Table 3-14**.

- The minimum and maximum feed requirement at Leib are 0.3 gpm and 74.0 gpm, respectively. This represents a very large turndown ratio, which will need to be accounted for in the chemical feed alternatives.
- Sizing of flow control valves and chemical feed recirculation pumps will be completed in the BOD phase based on system feed rate.
- Updating the SOP to replenish the sodium hypochlorite concentration when it falls below 10.0% (trade percent by weight) reduces the maximum feed rate by half (148 gpm to 74 gpm)

Table 3-14 Summary of Total Sodium Hypochlorite Feed Rate Requirements at Leib

Parameter	Units	Current Collection System Average	Future Collection System Average
Min Flow	gpm	0.3 ³	0.3 ³
Average Flow	gpm	3.2 ²	10.1 ²
Peak Flow	gpm	52.2 ¹	74.0 ²

¹sodium hypochlorite concentration of 5.0%, high ICT

²sodium hypochlorite concentration of 10.0%, average ICT

³sodium hypochlorite concentration of 13.0%, low ICT

A comparison of the historic and proposed sodium hypochlorite usage (lbs/MG) is shown in **Table 3-15**. The historic usage is based on historic storm event data and sodium hypochlorite storage tank levels from GLWA's SCADA system and GLWA's bleach report test results. The proposed sodium hypochlorite usage is based on the chlorine dose response testing results, ICT values, and portioning of the design storm first flush and post first flush storm volumes. For Oakwood, the proposed ICT method would result in a 105% difference (320% decrease) for the existing basins without the baffle alternative or approximately 112% difference (353% decrease) with the baffle alternative installed in the existing basins. For Leib, there is virtually no difference in proposed and historic sodium hypochlorite usage.

Table 3-15 Comparison of Historic and Proposed Sodium Hypochlorite Usage

Parameter	Units	Oakwood	Leib
Average Historic Sodium Hypochlorite Usage ¹	lbs/MG	230	58
Proposed Sodium Hypochlorite Usage ²	lbs/MG	72 (existing basins without baffles) 65 (with baffle alternative)	58
Percent Reduction	%	105 (existing basins without baffles) 112 (with baffle alternative)	0

¹historic data from **Figures 3-8 and 3-9**, usage based on proportioned ICT method with high ICT for first flush storm volume and average ICT for post first flush storm volume.

²usage based on proportioned ICT method with high ICT for first flush storm volume and average ICT for post first flush storm volume, averaged usage across design storms (6-month, 24-hour,10-year, 24-hour)

The relatively large difference between historic and proposed sodium hypochlorite usage at Oakwood (105 to 112% different) is largely a function of the average historic sodium hypochlorite at Oakwood being considerably higher (230 lbs/MG) than the historic average at Leib (58 lbs/MG). By reducing the amount of sodium hypochlorite (lb.) added per a unit storm volume (MG) while maintaining disinfection compliance, GLWA can optimize the sodium hypochlorite feed system, reduce sodium hypochlorite usage, and ultimately reduce operating cost.

4.0 Description of Alternatives

The following sodium hypochlorite feed alternatives were evaluated:

- Recirculation loop with control valves (Section 4.1)
- Gravity feed with control valves (Section 4.2)
- Metering pumps (Section 4.3)
 - Gear pumps
 - Diaphragm pumps
 - Peristaltic pumps

Each alternative is described in the following subsections.

Per the scope of work, the “status quo” option for keeping or replacing in kind the existing chemical feed system at Oakwood and Leib was not evaluated as the existing chemical feed systems do not meet project goals (simplify feed system, improve maintenance access, increase turndown capability, replace aging, unreliable, and/or expensive to maintain existing feed equipment, etc.).

As discussed in Section 3, the existing sodium hypochlorite storage tanks do not provide adequate storage for the future collection system peak design storm and will need to be replaced in coordination with proposed collection system modifications. Accordingly, keeping the existing storage tanks was not considered as an alternative; however, the existing storage tanks can be used until the proposed collection system modifications are substantially completed. Installing new larger capacity tanks within the existing chemical storage rooms at each facility was evaluated because expanding the existing chemical storage rooms and providing additional tanks was not warranted based on the results of the chlorine dose response testing and design storm evaluations. The installation of the new larger capacity tanks is discussed in additional detail in Section 4.4.

4.1 Recirculation Loop with Centrifugal Pumps and Flow Control Valves

A recirculation loop system consisting of centrifugal sealless, magnetic drive pumps with a common discharge and suction header (with redundant backup discharge header), and motorized flow control valves (FCV) at each feed point is recommended as an alternative to the existing chemical feed systems at both Oakwood and Leib for the following reasons.

Flow and head capacity:

- Pumps can provide up to 1,450 gpm and 490 feet of head (maximums are mutually exclusive), which provides sufficient flow capacity and head for Oakwood and Leib's feed systems (current and predicted future flows).
- The recirculation loop can require up to four times the design flow to maintain adequate pressure and flow across the discharge header under the various design conditions. The recirculation loop flow requirements will be further evaluated through detailed hydraulic modeling during the preliminary design phase.
- Provides the ability to reduce the number of feed pumps and simplify O&M activities.

Materials of construction:

- This type of pump is offered with non-metallic materials of construction with excellent resistance to sodium hypochlorite (<20% trade percent by weight).
 - Fiberglass reinforced plastic (FRP)
 - Glass-fiber reinforced polypropylene (GF PP)
 - Carbon-fiber reinforced PVDF (CF PVDF)

Flow control valve considerations:

- **Turndown limitations:** The turndown capacity and ability to meet low flow requirements is largely dictated by the FCV stroke. Typically, FCV can achieve a turndown of 50:1.

- **Accuracy and Repeatability:** high-performance FCV can provide consistent flow across a broad range of flows and pressures.
- **Reliability:** FCV operate on the basic principle of restricting flow through a select orifice size to induce a specific headloss resulting in a corresponding flow

The valve will need a minimum 10% stroke to ensure adequate flow control is provided under the low flow condition. The FCV will need a large turndown capacity (typically 1:50 or greater) within the recommended percent valve opening (10% to 90% of stroke rule of thumb) to provide sufficient operational flexibility and meet low and high flow requirements. These requirements will need to be carefully evaluated and coordinated with valve manufacturers throughout design progression to verify the FCVs can reliably meet the design requirements. This approach to chemical feed with a recirculation loop and FCVs was discussed and recommended in CS-299 CSO Facilities Assessment. The advantages and disadvantages associated with this chemical feed alternative are shown in **Table 4-1**.

Table 4-1 Advantages and Disadvantages for Chemical Feed Recirculation Loop with Centrifugal Pumps and Flow Control Valves

Advantages	Disadvantages
Simplifies sodium hypochlorite feed system by reducing the number of pumps, which may provide additional space for operation and maintenance activities in the existing chemical storage and feed rooms	High performance FCVs for sodium hypochlorite application can be costly. Opportunities to use less costly valves with downstream backpressure valves can be further evaluated through design progression.
Offers excellent chemical compatibility with non-metallic materials of construction to extend service life	Numerous valves and actuators that will require maintenance to ensure accurate flow control
FCVs offer large turndown capacity (typically 1:50)	Backup manual flow control would be complex when multiple storm pumps are active
By reducing the number of pumps, centrifugal pumps can be less maintenance intensive than gear, diaphragm, and hose pumps.	Chemical feed recirculation loops are used throughout the water and wastewater industry for sodium hypochlorite applications; however, not to the same degree as gear, diaphragm, and hose pumps (i.e., less industry experience to leverage).
Maintains existing chemical feed system redundancy (n+1)	
Reduction in number of pumps will reduce capital, operation, and maintenance costs	
GLWA staff at Oakwood and Leib are experienced with the operation and maintenance of centrifugal pumps.	

4.2 Gravity Feed with Control Valve

This alternative utilizes the gravity head available between the liquid level in the chemical storage tank and the elevation of injection location and FCV for chemical feed. **Figure 4-1** shows the simple schematic of the gravity feed with control valve alternative. The motor actuated control valve could be a typical FCV used for accuracy, reliability, and repeatability. The FCV will need to have

minimum 10% stroke for controllability for the low flow condition. Manufacturers recommended having a minimum 3 psig pressure drop across the valve and a minimum 5 psig upstream pressure for reliable, accurate and repeatable flow control.

Figure 4-1
Gravity Flow Control Valve Alternative Schematic

Table 4-2 summarizes the pressure needed upstream and downstream of the FCV and respective FCV elevation and the tank minimum liquid levels required for use of gravity FCV. The lack of valve upstream pressure generated with a gravity feed do not make the application feasible.

Table 4-2 Gravity Flow Control Valve Feasibility

Parameters	Units	Oakwood Facility	Leib Facility
Assumed Pressure at Injection	psig	15.7	--
Assumed Minimum Back Pressure at Injection Mixer Panel	psig	10	10
Assumed Piping Losses from FCV to the Mixer Panel	psig	2	2
<i>Pressure Needed Downstream of FCV (Subtotal of Pressure Needed Downstream of FCV)</i>	<i>Psig/Ft</i>	<i>27.7/64</i>	<i>12/27.7</i>
Pressure Drop Across FCV Needed for Appropriate Valve Sizing	psig	3	3
Assumed Piping Losses from Chemical Storage Tank to FCV	psig	3	3
Total Pressure Difference from Tank Liquid Level to Injection Location	psig/Ft	33.7/77.8	18.0/41.6
Injection Panel Location Approximate EL	Ft	92.0	120.0
Minimum Liquid Level Needed EL	Ft	169.8	161.6
Existing Chemical Tank Approximate Maximum Liquid Level EL	Ft	114.0	147.5
Existing Chemical Tank Approximate Minimum Liquid Level EL	Ft	103.8	138.5
<i>Feasible by Gravity Flow?</i>		<i>No</i>	<i>No</i>

Note: 1. Pressures and elevations are assumed approximately for the feasibility evaluation.

A safety factor will need to be added in the required gravity head for the accurate and reliable chemical application. As presented in **Table 4-2**, gravity feed with FCVs is not feasible a feasible option for disinfection application at both Oakwood and Leib. Accordingly, the advantages and disadvantages associated with this chemical feed alternative are not discussed.

4.3 Metering Pumps

Metering pumps discharge a known volume of chemical per pump action, are commonly used in chemical injection applications, and are presently used at Leib (diaphragm pumps) and Oakwood (gear pumps). Gear, diaphragm, and peristaltic pumps are discussed in the following subsections.

4.3.1 Gear Pumps

Gear pumps are used at Oakwood to feed sodium hypochlorite. GLWA reported the gear pumps perform well; however, rebuild cost is considerable because of the cost of the materials of construction. CDM Smith consulted with gear pump manufacturers to evaluate available alternative materials of construction that are compatible with sodium hypochlorite and available for pumps that provide adequate flow and head for the Leib and Oakwood feed systems.

Gear pumps are not recommended as an alternative for the following reasons:

- **Capacity limitations:** Seven of the existing ten gear pumps are the largest available gear pumps so opportunities to consolidate and simplify the existing gear pump-based feed system without sacrificing redundancy does not exist.
- **Materials of construction limitations:** Materials of construction vary with pump capacity based on available pump configurations and are summarized below. This list is not exhaustive and includes materials available from sampling of qualified pump manufacturers. Existing pumps are constructed of Hastelloy C wetted components, which appears to be the most cost-effective material of construction considering the desire to simplify chemical feed systems and reduce lifecycle costs.
 - **Titanium:** Titanium provides excellent resistance to sodium hypochlorite (<20% trade percent by weight). Only very small (<4 gpm) pumps are available with titanium wetted components.
 - **PTFE lined PVDF(Kynar):** PTFE and PVDF provide excellent resistance to sodium hypochlorite (<20% trade percent by weight). However, PTFE lined PVDF pumps have a maximum flow capacity of 33 gpm, which would require nearly the same pumps as the existing feed system to meet the maximum flow requirements.
 - **Hastelloy C:** Hastelloy C provides good sodium hypochlorite resistance (<20% trade percent by weight). Manufacturers only offer Hastelloy C wetted components for pumps large enough to meet the maximum flow requirements at Oakwood and Leib.
 - **Per- and polyfluoroalkyl (PFA) lined 316 Stainless Steel:** PFA offers excellent resistance to sodium hypochlorite (<20% trade percent by weight); however, once the lining fails the base material (316 stainless steel) offers poor resistance to sodium hypochlorite. Smaller pumps (<25 gpm) are available with PFA lined 316 stainless steel wetted components. The lining would have to be periodically inspected, which would require dismantling the pump head (i.e., additional O&M).

The advantages and disadvantages associated with this chemical feed alternative are shown in **Table 4-3**.

Table 4-3 Advantages and Disadvantages for Chemical Feed Using Gear Pumps

Advantages	Disadvantages
GLWA staff at Oakwood and Leib are experienced with the operation and maintenance of gear pumps.	Capacity limitations of gear pumps does not allow feed system to be simplified.
Gear pumps are used throughout the water and wastewater industry for sodium hypochlorite applications, which provides considerable industry knowledge and experience.	Materials of construction are relatively expensive and only Hastelloy C and PFA lined 316 stainless steel are offered in pumps with sufficient capacity to meet the feed requirements at Oakwood and Leib.
	Given multiple gear pumps are required to meet chemical feed requirements, gear pumps can be more maintenance intensive than centrifugal pumps.
	Multiple gear pumps will increase capital, operation, and maintenance cost in comparison to recirculation loop alternative.

4.3.2 Diaphragm Pumps

Diaphragm metering pumps are used at Leib. GLWA staff reported that the pumps perform relatively well. However, the chemical feed system is complex, crowded within the containment area, and pump maintenance is relatively expensive due to the materials of construction.

Diaphragm pumps are not recommended as an alternative due to capacity limitations, specifically:

- **Capacity limitations:** the maximum flow capacity of available diaphragm pumps (~40 gpm) is considerably lower than the required flow, which limits opportunities to reduce the number of pumps, decrease O&M cost, and chemical feed system complexity.

The advantages and disadvantages associated with this chemical feed alternative are shown in **Table 4-4**.

Table 4-4 Advantages and Disadvantages for Chemical Feed Using Diaphragm Metering Pumps

Advantages	Disadvantages
Materials of construction (e.g., glass filled PTFE) are robust and compatible with sodium hypochlorite (<20% trade percent by weight) allowing for reasonably long service life.	Capacity limitations of diaphragm metering pumps does not allow feed system to be simplified.
GLWA staff at Oakwood and Leib are experienced with the operation and maintenance of diaphragm pumps.	Given multiple diaphragm pumps are required to meet chemical feed requirements, diaphragm metering pumps can be more maintenance intensive than centrifugal pumps.
Diaphragm pumps are used throughout the water and wastewater industry for sodium hypochlorite applications, which provides considerable industry knowledge and experience.	Multiple diaphragm pumps will increase capital, operation, and maintenance cost in comparison to recirculation loop alternative.
	Materials of construction are relatively expensive

4.3.3 Peristaltic Pumps

Peristaltic pumps are not used a Leib or Oakwood; however, are a viable option in terms of flow capacity (up to 317 gpm) and materials compatibility (variety of compatible hose materials).

Peristaltic pumps are not recommended as an alternative for the following reasons:

Maintenance Challenges:

- Hoses can break which can:
 - Require staff to handle corrosive sodium hypochlorite in the pump head in order to replace the hose.
 - Require backup pump to maintain operations.
- Requires additional O&M in comparison to centrifugal and gear pumps:
 - Pulsation dampeners.
 - Bump pumps periodically for rotation to relieve pressure points that form when rollers sit idle and to keep the hose lubricated/wet so it does not dry out.
 - Replace hose periodically.

The advantages and disadvantages associated with this chemical feed alternative are shown in **Table 4-5**.

Table 4-5 Advantages and Disadvantages for Chemical Feed Using Peristaltic Metering Pumps

Advantages	Disadvantages
Wide variety of hose materials that are compatible with sodium hypochlorite (<20% trade percent by weight).	Peristaltic metering pumps can be more maintenance intensive than other metering pump options, particularly the hoses which can become a nuisance.
Capacity of peristaltic metering pumps allows the existing feed system to be simplified but not to the same degree at centrifugal pumps with a recirculation loop.	Given multiple peristaltic metering pumps are required to meet chemical feed requirements, peristaltic metering pumps can be more maintenance intensive than centrifugal pumps.
Peristaltic metering pumps are used throughout the water and wastewater industry for sodium hypochlorite applications, which provides considerable industry knowledge and experience.	Multiple peristaltic metering pumps will increase capital, operation, and maintenance cost in comparison to recirculation loop alternative.
Materials of construction are relatively inexpensive, although some hose materials can be costly and require relatively frequent replacement.	GLWA staff at Oakwood and Leib may not be as experienced with the operation and maintenance of peristaltic pumps as gear, diaphragm, or centrifugal pumps.

4.3 Alternatives Recommended for Analysis

4.3.1 Not Recommended Alternatives

The following alternative are not recommended for analysis at Oakwood and Leib:

- Gravity feed with control valve
- Gear pumps
- Diaphragm pumps
- Peristaltic pumps

4.3.2 Recommended Alternatives

The following alternatives are recommended for analysis at Oakwood:

- Recirculation loop with centrifugal pumps and FCVs

The following alternatives are recommended for analysis at Leib:

- Recirculation loop with centrifugal pumps and FCVs

4.4 Increasing Sodium Hypochlorite Storage Capacity

The chemical storage rooms at Oakwood and Leib are compact and installing larger tanks will be challenging. The existing tanks can be removed, and new tanks can be installed using the knockout walls at each facility. The sequence of construction and other constraints are discussed in additional detail in the following subsections.

4.4.1 Oakwood

The existing sodium hypochlorite storage room is shown in plan and section view in **Figure 4-2** and **Figure 4-3**. The two existing 11,500-gallon tanks are located on concrete tank pads and aligned with two 16 ft 0 in. x 16 ft-0 in. (length x width) removable wall systems (i.e., concrete masonry unit (CMU) knockout walls). Using taller storage tanks would preclude the need to modify the existing concrete tank pads to accommodate larger diameter tanks. Based on initial evaluations, it does not appear necessary to consider larger diameter tanks, which can be more difficult to ship and install within the existing chemical storage room. The new larger storage tanks would be taller tanks given the tight footprint of the existing room and limited space to increase the existing tank pads if needed to accommodate larger diameter tanks.

Figure 4-2
Existing Chemical Storage Room at Oakwood Plan View

Figure 4-3
Existing Chemical Storage Room at Oakwood Section View

The proposed 15,000-gallon storage tanks are shown conceptually in **Figure 4-4**. The height of the tanks would need to increase approximately 3 feet to provide the required storage as discussed in Section 3. cursory field investigations and review of record drawings indicate the existing chemical storage room can accommodate the taller tanks; however, a more detailed field investigation is warranted to confirm field conditions and further evaluate construction constraints. A preliminary structural evaluation of the existing concrete tank pads was conducted, and the existing pads can accommodate the additional loads associated with the proposed larger sodium hypochlorite storage tanks. A more robust analysis should be completed as the design advances and the chemical storage sizing is further refined.

Figure 4-4
Proposed Larger Chemical Storage Tanks at Oakwood

The existing vent, overflow, water, and fill lines shown in **Figure 4-5** would need to be modified to accommodate the taller tanks. It appears there is sufficient clearance between the existing ceiling system and the top connections for the proposed taller tanks to allow for these piping modifications. There does not appear to be any conflicts with structural members, lighting, or HVAC ducts; however, conduit to the level sensor would need to be relocated and the clearance for the fire suppression system would need to be field verified. It appears there is adequate secondary and chemical spill containment volume to accommodate the proposed larger capacity tanks. A more detailed evaluation should be completed in subsequent design phases to verify the existing secondary chemical storage volume based on field conditions. This would include field investigations and field measurements.

There is between 4 ft-5 in. and 4 ft-9 in. feet of headspace above the proposed taller storage tanks, which does not provide adequate height for someone to stand on the tank. Access platforms would be located adjacent to the tanks to provide access to the tank connections and level sensor. To the extent practical, tank connections (piping and instrumentation) should be located along the perimeter of the tank to allow the connections to be accessed from the side of the tank. The piping

connections would only need to be accessed to address a leak or to replace the piping, which would be an infrequent activity. The level sensor needs to be routinely calibrated. Locating the level sensor connection near the sidewall of the tank would provide adequate access from the proposed access platform to remove, calibrate, and reinstall the sensor.

During the CSO Facilities Improvements Workshop GWLA requested that the access to the top of the tanks be interconnected with a catwalk or similar access platform to allow someone to access the top of the tanks from a single ladder climb. CDM Smith will explore opportunities to incorporate this access feature into the design during the basis of design phase.

Figure 4-5
Existing Sodium Hypochlorite Storage Tank at Oakwood

Installation of the proposed new sodium hypochlorite tanks will generally include:

- Temporarily disconnecting

- Emergency eyewash and shower supply (provide temporary eyewash and shower, storage tank no. 2 only)
- Conduit and associated junction boxes along east wall mounted to removable wall system
- Chemical sump suction and discharge piping (storage tank no. 1 only)
- Removing CMU knockout wall section(s)
- Verifying there is a relatively dry weather outlook to avoid undue risk of a large storm event occurring during storage tank replacement work
- Providing temporary wall system and temperature controls to prevent freezing temperatures, reduce degradation of sodium hypochlorite at high temperatures, and keep facility secure during replacement.
- Disconnecting piping, instruments, and appurtenance from one tank and removing the tank
- Installing new tank, piping, instruments, and appurtenances
- Test and commission tank
- Disconnecting piping, instruments, and appurtenances from second tank and removing the tank
- Installing second new tank, piping, instruments, and appurtenances
- Test and commission second tank

4.4.2 Leib

The existing sodium hypochlorite storage room is shown in plan and section view in **Figure 4-6** and **Figure 4-7**. The two existing 10,450-gallon tanks are located on concrete tank pads and aligned with the single 16 ft-0 in. x 13 ft-0 in. (length x width) removable wall system (i.e., CMU knockout wall). The new larger storage tanks would be taller tanks given the tight footprint of the room and limited space to expand the existing tank pads if needed to accommodate larger diameter tanks.

Figure 4-6
Existing Chemical Storage Room at Leib Plan View

Figure 4-7
Existing Chemical Storage Room at Leib Section View

The proposed 12,600-gallon storage tanks are shown conceptually in **Figure 4-8**. The height of the tanks would need to increase approximately 3-feet to provide the required storage (working volume increase) as discussed in Section 3. Cursory field investigations and review of record drawings indicate the existing chemical storage room can accommodate the taller tanks; however, a more detailed field investigation is warranted to confirm field conditions and further evaluate construction constraints. A preliminary structural evaluation of the existing concrete tank pads was conducted, and the existing pads can accommodate the additional loads associated with the proposed larger sodium hypochlorite storage tanks. A more robust analysis should be completed as the design advances and the chemical storage sizing is further refined.

Figure 4-8
Proposed Larger Chemical Storage Tanks at Leib

The existing vent, overflow, water, and fill lines shown in **Figure 4-9** would need to be modified to accommodate the taller tanks. It appears there is sufficient clearance between the existing metal trusses and the top connections for the proposed taller tanks to allow for these piping modifications. There does not appear to be any conflicts with structural members, lighting, HVAC ducts, conduit, etc. It appears there is adequate secondary and chemical spill containment volume to accommodate the proposed larger capacity tanks. A more detailed evaluation should be completed in subsequent design phases to verify the existing chemical storage volume based on field conditions.

During the CSO Facilities Improvements Workshop GWLA requested that the access to the top of the tanks be interconnected with a catwalk or similar access platform to allow someone to access the top of the tanks from a single ladder climb. CDM Smith will explore opportunities to incorporate this access feature into the design during the basis of design phase.

Figure 4-9
Existing Sodium Hypochlorite Storage Tank at Leib

Installation of the proposed new sodium hypochlorite tanks will generally include:

- Temporarily disconnect and protect chemical sump pump and suction and discharge piping, particularly the portion of discharge piping that runs along the removable wall system.
- Removing CMU knockout wall section
- Verifying there is a relatively dry weather outlook
- Providing temporary wall system and temperature controls to prevent freezing temperatures, reduce degradation of sodium hypochlorite at high temperatures, and keep facility secure during replacement.
- Relocating tank closest to the CMU knockout wall outside the facility and installing temporary connections from the tank to the existing chemical feed system to serve as backup sodium hypochlorite storage in the event the facility activates during storage tank replacement work.
- Removing second tank (furthest from knockout wall)
- Installing new tanks, piping, instruments, and appurtenances
- Test and commission tanks
- Disconnecting temporary connections to existing tank located outside and connect new storage tanks to chemical feed system.

5.0 Alternatives Analysis

The following subsections (Sections 5.1 and 5.2) discuss the recommended chemical feed alternative for Oakwood and Leib: recirculation loop with centrifugal pumps and FCVs. Section 5.3 discusses the chemical storage alternatives for replacing the existing storage tanks with larger tanks.

5.1 Oakwood Chemical Feed Analysis

5.1.1 Recirculation Loop with Centrifugal Pumps and Flow Control Valves

Recirculation Pumps. The sodium hypochlorite recirculation pumps are designed to recirculate sodium hypochlorite from the bulk storage tanks, through one of two redundant discharge headers and back to the storage tanks in a continuous recirculation loop. It is assumed that the recirculation loop requires four times the peak design capacity to maintain adequate flow and pressure in the discharge header under all design conditions. This assumption will be verified with detailed hydraulic modeling in subsequent design phases. Therefore, the hypochlorite recirculation pumps will be designed to deliver a nearly constant flow of around four times higher than the maximum total facility dose requirement using constant-speed motors.

Due to the corrosive nature of sodium hypochlorite solutions, corrosion-resistant centrifugal pumps with seal-less magnetic drives will be used for the recirculation pumps. All wetted parts of the pump will be made of Teflon or a proprietary plastic material (BPO-DMA) manufactured by

Dow chemical specifically for sodium hypochlorite applications. **Figure 5-1** shows a typical corrosion-resistant pump manufactured by FYBROC. Two duty and two standby pumps are provided to ensure continuous operation in the event that two pumps are out of service. **Table 5-1** presents the basis of design for the sodium hypochlorite recirculation pumps.

Corrosion-Resistant Centrifugal Pump Series 2530 Manufactured by FYBROC.

Table 5-1 Sodium Hypochlorite Recirculation Pumps Design Criteria

Parameters	Criteria
Type	Plastic Centrifugal
Total No. of Pumps	4
No. of Duty Pumps	2 (duplex configuration)
No. of Standby Pumps	2
Suction Pipe Size	6-inch flanged
Discharge Pipe Size	4-inch flanged
Pump Materials of Construction	FRP w/ BPO-DMA cure system
Pump Drive	Constant-speed motor with seal less mag drive

Hypochlorite Flow Control Valve Station. The sodium hypochlorite valve stations are designed to provide accurate dosing of sodium hypochlorite at the six application points located on each storm discharge pipe. Each station includes a magnetic flowmeter, globe or v-port ball valve FCVs, with manual bypass connection. The existing potable water connection and in-line static mixer assembly would be retained and continue be used to blend the sodium hypochlorite and water supply flow streams. The globe valves are designed to deliver precision dosing control over a relatively large

range in flows (e.g., 50:1 turndown capacity). The motor-operated duty FCV modulates in response to a flow signal produced by the magmeter to meet the setpoint dose for each chemical.

Two motor operated FCVs would be provided to meet the flow range requirements. The valves will likely operate in a duty/standby mode under low to moderate flows and split the flow and operate in parallel when transitioning from moderate to high flows. A third manually operated FCV will be provided as a backup standby. Opportunities to reduce the number of motor operated FCVs and reduce the associated operation and maintenance needs will be further evaluated with design progression.

A valved drain will be provided upstream of each FCV for backflushing the valve station with potable water to remove any scale deposits that accumulate in the FCV over time. Due to the corrosive nature of sodium hypochlorite, all wetted parts of the FCV will be made of titanium or Hastelloy C. An example of an FCV is shown in **Figure 5-2**. **Table 5-2** presents the basis of design for the chemical FCVs.

Oakwood Retention and Treatment Basin Chemical Feed Alternative Process Flow Diagram

Figure 5-4
Oakwood Conceptual Layout of Recirculation Loop and Flow Control Valve.

5.2 Leib Chemical Feed Analysis

5.2.1 Recirculation Loop with Centrifugal Pump and Flow Control Valves

The recirculation loop and FCV system configuration at Leib would be similar to Oakwood; however, there would likely be two centrifugal pumps (1 duty and 1 standby). The maximum flow at Leib (950 cfs/613 mgd) is about 30% lower than the maximum flow at Oakwood (1,231 cfs/794 mgd), which likely avoids needing a duplex pump configuration at Leib.

Table 5-3 Sodium Hypochlorite Recirculation Pumps Design Criteria

Parameters	Criteria
Type	Plastic Centrifugal
Total No. of Pumps	2
No. of Duty Pumps	1
No. of Standby Pumps	1
Suction Pipe Size	6-inch flanged
Discharge Pipe Size	4-inch flanged
Pump Materials of Construction	FRP w/ BPO-DMA cure system
Pump Drive	Constant-speed motor with seal less mag drive

The FCV stations at Leib would be similar to Oakwood; however, the FCVs may be slightly smaller at Leib than Oakwood as the maximum total facility flows (52.2 gpm current collection system, 74.0 gpm future collection system) is lower than Oakwood (113.1 gpm current collection system, 126.0 gpm future collection system).

The existing disinfection equipment control panels are located in the existing chemical room, which is a corrosive environment and has limited room for staff access around process equipment and tanks. To improve equipment access in alignment with the guiding principles (i.e., provide equipment which is accessible and easy to maintain) and to protect the control panels from the corrosive environment, the new control panels for disinfection equipment will be located outside of the existing chemical room. Locations will be determined once the size and number of panels needed is determined.

Table 5-4 Flow Control Valve Design Criteria

Parameters	Criteria
Type	Globe, V-Port Ball Valve
Total No. of Valves	14
Total No. of Valve Stations	7
No. of Valves Per Valve Station	3
No. of Motor-Operated Valves Per Valve Station	2
No. of Manual Standby Valves Per Valve Station	1
Maximum Turndown Ratio	50:1
Materials of Construction	Titanium or Hastelloy C
Type of Valve Actuator	Electric
Actuator Power	110/60 VAC
Control Signal	4-20 mA

The existing chemical mixers (co-current prechlorination and counter-current mixing chamber mixers) control panels are not explosion proof and will need to be replaced with NEMA 7 explosion proof enclosures to meet area classification requirements. The mixers have submersible enclosures which satisfies the area classification requirements. It is recommended that the enclosures be replaced as part of the disinfection system upgrades.

A process flow diagram and conceptual layout for the proposed recirculation loop and FCV system are shown in **Figure 5-5** and **Figure 5-6**. The valve size, type, materials of construction, valve station configuration, operational flow capacity, and other design criteria will be further evaluated during the basis of design phase in collaboration with GLWA.

TM-20 Chlorine System Alternatives

June 1, 2023

Page 83

Figure 5-5
Leib Screenings and Disinfection Facility Chemical Feed Alternative Process Flow Diagram

Page 84

A life cycle cost analysis was not performed because only one alternative (recirculation loop with centrifugal pumps and FCVs) was identified as technically feasible and capable of meeting project goals.

5.3 Chemical Storage Analysis

The new larger sodium hypochlorite storage tanks would generally match the existing storage tank design given the existing size constraints, specifically:

- Existing removable wall system dimensions
- Limited space to expand existing concrete tank pads – particularly at Leib
- Height restrictions – although less constrictive than diameter limitations, there is limited overhead space in the existing chemical storage rooms and there needs to be enough clearance to stand the new taller tanks up in the existing chemical storage rooms

However, there are alternative tank materials that offer different anticipated useful life with varying capital and maintenance costs that can be considered for this application. For bulk sodium hypochlorite 15% trade percent by weight, there are three primary tank construction options: crosslinked polyethylene (XLPE), lined carbon steel, and reinforced fiberglass (FRP). The existing tanks at Oakwood and Leib are FRP and designed to store sodium hypochlorite up to 15% (trade percent by weight) with a specific gravity of 1.25. The anticipated useful life and cost comparison of the different tank materials are shown in **Table 5-5**.

Table 5-5 Sodium Hypochlorite Storage Tank Material Comparison

Tank Material	Capital Cost	Maintenance Cost	Anticipated Useful Life
XLPE	\$	\$	4 – 7 years
Lined Carbon Steel	\$\$	\$\$	3 – 6 years for liner
FRP	\$\$	\$	10 – 15 years

Table adapted from Protank Sodium Hypochlorite Storage Tanks and Specifications article.

<https://www.protank.com/sodium-hypochlorite#:~:text=Sodium%20Hypochlorite%20Storage%20Tanks%20are,from%2035%20to%20100%2C000%20gallons.>

The advantage and disadvantages associated with each tank material are shown in **Table 5-6** through **Table 5-8**.

Table 5-6 Advantages and Disadvantages for XLPE Tanks

Advantages	Disadvantages
Relatively low capital cost in comparison to lined carbon steel and FRP tanks	Tendency to leak at penetrations for fittings
Little to no maintenance (i.e., no liner to replace)	Does not last as long as FRP tanks
No seams, which can be weak points in the tank	

Table 5-7 Advantages and Disadvantages for Lined Carbon Steel Tanks

Advantages	Disadvantages
Steel tanks can last for 15+ years if liners are replaced routinely	Higher maintenance cost than XLPE and FRP tanks because liner must be replaced every 3 to 6 years, which requires draining and taking tank offline
	Relatively high capital cost in comparison to XLPE and FRP tanks
	Liner replacement often requires third-party to replace, which adds to maintenance cost

Table 5-8 Advantages and Disadvantages for FRP Tanks

Advantages	Disadvantages
Longest expected useful life in comparison to lined carbon steel tanks and XLPE	Comparable capital cost to lined steel tanks, more costly than XLPE tanks

It is recommended that the existing FRP tanks be replaced with new, larger FRP tanks, which offer the longest anticipated service life of the materials considered in this analysis without needing to periodically replace a liner system. The additional capital cost compared to XLPE is counteracted by the superior durability and lower tendency to leak (i.e., no need to penetrate tank shell to attached fittings).

6.0 Summary and Recommendations

The following recommendations are provided for the disinfection systems at Oakwood.

- Conduct additional bacteria and chlorine dose response testing to further validate sample results and refine ICT values.
 - Continue testing through the implementation phase to further refine and validate ICT results particularly to examine seasonal variability.
 - Conduct additional testing for high flow events, especially once the proposed ODIRS is constructed to validate the ICT values and opportunities to reduce the TRC required.
- Replace the existing sodium hypochlorite feed system with a recirculation loop and control valve system.

- Update the SOP to maintain a sodium hypochlorite concentration of 10.5% (median historic concentration) to help meet future chemical storage requirements and reduce the maximum sodium hypochlorite feed rate.
- Plan to replace the two existing 11,500-gallon chemical storage tanks with two new 15,000-gallon tanks in coordination with the construction of the ODIRS and associated increase in future storm volumes.
- Installing baffles in the existing CSO basins could reduce the TRC required at the end of the CSO basins, which in turn could reduce the chemical storage and feed requirements.
 - Chemical storage requirements would be reduced by approximately 3,000 gallons, which would decrease the required storage tank size from two 15,000-gallon tanks to two 13,500-gallon tanks (~11% decrease).
 - The maximum feed requirement could be reduced by approximately 15%, which could reduce the horsepower for the proposed centrifugal pumps.
 - While the reduction in chemical storage and feed is appreciable, it does not mitigate the need to replace the existing chemical storage tanks or considerably change the pump selection or number of feed pumps. Therefore, it is not recommended that baffles be installed in the CSO basins at Oakwood. If quenching is required in the future at the end of the CSO basins to counteract the high TRC requirements during high flows, installing baffles in the CSO basins may be beneficial.

The following recommendations are provided for the disinfection systems at Leib.

- Conduct additional bacteria and chlorine dose response testing to further validate sample results and refine ICT values.
 - Continue testing through the implementation phase to further refine and validate ICT values particularly to examine seasonal variability.
- Replace the existing sodium hypochlorite feed system with a recirculation loop and control valve system.
- Update the SOP to maintain a sodium hypochlorite concentration of 10.0% to help meet future chemical storage requirements.
- Replace existing mixer enclosures with NEMA 7 explosion proof enclosures to meet area classification requirements.
- Plan to replace the two existing 10,450-gallon chemical storage tanks with two new 12,600-gallon tanks in coordination with the construction of the Meldrum Sewer and associated increase in future storm volumes.

7.0 Next Steps

The following are next steps required to advance the disinfection system improvements at Oakwood and Leib.

- Field Investigations
 - Collect field measurements to verify the existing secondary chemical containment volume is adequate for the proposed new chemical storage tanks.
 - Investigate construction sequencing elements and identify any additional components that would need to be temporarily relocated to facilitate the replacement of the existing chemical storage tanks.
- Vendor Coordination
 - Further develop chemical feed pump selection based on detailed hydraulic model of recirculation loop system. Verify recirculation flow requirements to refine flow estimate (i.e., four times the required total facility sodium hypochlorite flow). Verify materials of construction for wetted components and request detailed dimensional drawings for selected pumps to develop more detailed chemical feed system layouts. Verify constant speed pumps are appropriate and VFDs are not required for this application.
 - *Coordinate with vendors to establish typical lead time for selected chemical feed pumps and coordinate with GLWA to determine if an installed spare pump (N+1 redundancy) is desirable.*
 - Coordinate proposed tank sizing with vendors to verify dimensions including manways, pipe and instrument connections, and anchor locations, and associated construction sequencing requirements.
 - Further develop FCV and actuator selection (establish FCV configuration, select FCV type, determine application point feed requirements under various operational conditions, minimum and maximum feed capacity of proposed FCV using low, average, and high ICT values to represent the full range of anticipated chlorine dose and feed requirements, etc.). Examine vendors experience with sodium hypochlorite applications. Further evaluate materials of construction available from each vendor. Request detailed dimensional drawings to develop detailed dose control valve station layouts.
 - Establish minimum and maximum operational capacity (initial and future) of feed system to account for uncertainties in basis of design such as NWI and Meldrum sewer connection impact on chlorine demand.
- GLWA Coordination

- Review proposed chemical storage and feed improvements and obtain consensus on proposed improvements and timeline relative to the construction of the ODIRS and Meldrum Sewer.
- Investigate existing storm pump flowmeter issues and discuss topic with GLWA staff to determine if this issue was addressed or needs to be addressed as it impacts the automatic disinfection system control.
- Collaborate on chemical feed system layout to ensure there is adequate space for operation and maintenance activities. Identify preferences (equipment types, materials, colors, configurations, etc.) that should be integrated into the design. Consider how equipment, pipes, valves, tanks, etc. will be removed and replaced in the future to avoid additional work necessary to replace such items.
- Consider opportunities to reconfigure existing stairs and sump to allow access around all sides of the tanks.
- Conduct sampling program to further refine ICT values.
- Design Progression
 - Further develop layouts for the proposed dose control valve station, chemical feed pump, and associated piping, valves, and instruments. Verify location of dose control valve stations and coordinate power requirements with electrical team.
 - Develop preliminary piping and instrumentation diagrams (P&IDs) for the chemical storage and feed systems.
 - Develop baseline schedule and opinion of probable construction cost for the proposed disinfection system improvements.
 - Conduct detailed hydraulic model of proposed recirculation loop to determine flow requirements for maintaining adequate pressure and flow through the recirculation loop, pressure control setpoints, and design conditions for the FCVs.
 - *Evaluate whether a single backup dose control station can serve the small and large storm pumps (i.e., turndown capacity) or if two backup dose control stations are required – one for small storm pumps and one for large storm pumps.*
 - *Evaluate location of the recirculation loop discharge outlet on the storage tanks to reduce potential to degrade sodium hypochlorite through aeration, particularly during low flow and low demand storm events when recirculation flow would be relatively high.*

- Further develop proposed new sodium hypochlorite storage tank layouts with access platforms, instrument ports, and pipe connections. Consider whether access platforms can be interconnected between the storage tanks.
- Develop provisions to assist with draw fill operations at Oakwood where operators have to use relatively high chlorine doses during the draw period to account for the loss of chlorine residual in the basins between draw/fill events.
- Develop method for disposing dilute sodium hypochlorite through the sewer system when the solution degrades and needs to be replenished. Consider method for diluting solution further.
- GLWA noted during the CSO Facilities Improvements Workshop that, to the extent feasible it is desirable to have Oakwood and Leib disinfection system be similar to the St. Aubin system (designed by others) so operators would be familiar with the operation of both facilities. CDM Smith will coordinate with the St. Aubin design team to identify opportunities to coordinate the designs.

GLWA CSO Facilities Improvements Project
Proposed Disinfection Storage Design Criteria Approach for OKW and Leib
December 14, 2022
December 21, 2022 (comment responses)

Background

The design team is seeking feedback from GLWA on the basis of design for sizing the sodium hypochlorite tanks at both OKW and Leib. At continuously operated water and wastewater treatment facilities sodium hypochlorite (hypo) tanks are typically sized based upon:

- number of days of storage,
- stored hypo concentration,
- plant flow,
- chlorine dose.

Values for the above parameters can vary based upon regulatory and utility requirements, but many in the industry will use 15 days of storage, at the “as-delivered” hypo concentration, at max. month flow, and at average chlorine dose. While this approach works well for continuously operating facilities, other factors need to be considered when sizing hypo storage tanks at intermittently used facilities that are “event based” type facilities (i.e. activated during wet weather or snow melt events).

Proposed Design Criteria Approach

Because OKW and Leib are event based facilities rather than continuous flow based, it is recommended that the sodium hypochlorite tanks be sized based upon:

- number of design storm events
- Dilute hypo concentration (if stored dilute) or hypo concentration before being discarded (if stored at “as delivered” concentration)
- total volume per design storm event
- average chlorine dose

The original BOD for the Leib disinfection process utilized collection system modeling to identify the peak volume discharged through Leib during the simulation period. That volume was determined to be 225 MG, which was used to size the Leib hypo storage tanks.

At OKW the storage approach used, as summarized in the BOD, aligns with the recommended approach above. The 10 year, 1 hour design storm was used (48.5 MG) and then a safety factor of 2 (or 2 design storm events) was applied at a chlorine dose that was slightly higher than the design dose. The tanks were sized based upon 5% hypo concentration.

Recommendation

CDM Smith recommends the same approach used for the original sizing of the storage tanks at OKW be utilized during this project for sizing the hypo storage tanks at Leib and OKW. The table below summarizes the storm events CDM Smith recommends be utilized for the sizing of the storage tanks. These storm events come from the Design Event Memo dated 12/6/2022. The detailed basis of design criteria for the sizing of the storage tanks will be determined after the wet weather chlorine dose response testing results have been analyzed and the preliminary integrated CT value is determined at each facility to meet the permitted bacteria limit.

	Leib	Oakwood
Average Condition	6 month, 24 hr storm	6 month, 24 hr storm
Peak Condition	10 year, 24 hr storm	10 year, 24 hr storm

GLWA Input Request

We are seeking for GLWA's concurrence in using these storm events for the conditions above, and for the approach for sizing the sodium hypochlorite storage tanks.

GLWA Comments and CDM Smith Responses

1. A design event includes what, a typical first flush? I would look at this, and then a back to back event with similar bleach, but no real first flush since it would have been part of the previous event.

Response:

The design storm event includes the entire event, including first flush. To size the storage tanks we are looking at the total volume of flow that will entire the facility, and need to be disinfected, during that event. CDM Smith recommends sizing the hypochlorite storage system to handle, at minimum, back to back design storm events. The hypochlorite required for treating a single peak event will then be checked to confirm that the tanks are sized to handle that event, should the volume required be larger than the back to back average storm events.

2. I think we should define as a part of this really what is the minimum concentration of bleach necessary, and what size of events it would apply to.

Response:

The tanks are recommended to be sized based upon the lowest hypochlorite concentration before the chemical is discarded. GLWA staff have stated this concentration is 5%. CDM Smith is also in the process of evaluating the historic data GLWA has provided to determine what the lowest sodium hypochlorite concentration has been in the storage tanks to assess if the 5% value is suitable for the design criteria.

3. Average over how long? I'd be curious how this plays out for a longer event which would white wash the dose at the beginning of the event. How has CDM Smith sized previous clients, and how has that worked out over the long run? How was the original volume for Oakwood determined?

Response:

Because the project is looking to optimize the chlorine disinfection process, the average dose will first be calculated from the integrated CT (ICT) value determined from the Oakwood and Leib dose response testing. This average dose will be checked against a few historic storm events to determine if the average amount of chlorine (pounds of chlorine/MG treated in an event) seem reasonable compared to the values determined from the ICT approach.

The average dose is for calculating the storage volume. The feed rate is determined using the peak flow event. This approach has been utilized on other projects in the recent past. Since utilizing ICT to size storage and feed systems is relatively new approach, CDM Smith doesn't have any installations in operation. The Beaver Creek Satellite Treatment Facility in Albany, NY was sized based upon this approach. It will be operational in 2023.

The description of how the storage volume at Oakwood is described in the original text above.

*Subject: Oakwood CSO RTB CFD Modeling Report
Contract No. 2101475 - CSO Facilities Improvements Project*

1.0 Introduction and Purpose

The Oakwood Combined Sewer Overflow (CSO) Retention Treatment Basin (RTB), owned and operated by the Great Lakes Water Authority (GLWA) and constructed in 2012, is designed to capture, treat, and discharge combined sewage in the Oakwood combined sewage interceptor. The Facility can store up to 9 million gallons (MG) of combined sewage and a hydraulic capacity of 1,660 cubic feet per second (cfs). Treatment consists of screening and sodium hypochlorite disinfection.

GLWA plans to increase utilization of the Oakwood (OKW) CSO facility by diverting flow from the Northwest Interceptor (NWI) to the facility and is interested in increasing the hydraulic efficiency of the RTB. Increasing the hydraulic efficiency of the RTB would reduce the overall disinfection chemical usage, thereby reducing the overall cost of operations. Increased hydraulic efficiency could be achieved by creating a more serpentine flow path to improve the plug flow characteristics of the basin. Computational fluid dynamics (CFD) modeling was used as a tool to evaluate the existing RTB and a proposed serpentine baffling configuration to achieve the desired increase in hydraulic efficiency.

The purpose of this technical memorandum (TM) is to summarize the CFD modeling work performed to evaluate and compare the hydraulic efficiency of the existing Oakwood CSO RTB to a serpentine-baffled configuration designed to encourage plug flow characteristics.

2.0 System Description

Combined sewage is conveyed to the RTB via eight storm pumps. Sodium hypochlorite is added to the combined sewage at the discharge of the storm pumps in the screening facility where the sewage is subsequently screened through six channels containing Andritz porous-plate step screens. Flow exits the screening facility and enters two parallel contact chambers, each with three

influent gates. Each contact chamber contains a long, straight influent weir and when the water level exceeds the elevation of the influent weir, the disinfection contact chambers begin to fill. When the water level reaches the elevation of the effluent finger weirs, the storage capacity of the RTBs is reached, and additional flow is discharged to the CSO outfall. The RTB contact chambers include multiple low “training walls” and flushing gates that guide flow used for flushing solids that settled after a CSO event has ended, and scum baffles designed to capture and prevent floatables from discharging over the effluent weirs.

3.0 Analysis Methodology

Disinfection efficacy has been shown to have a strong correlation with the disinfection dosage requirement, which is based on contact time (CT), the product of the disinfectant residual concentration and the CT. The CT component is dependent on the hydraulic efficiency of the contact tank where the ideal condition is uniform (plug) flow through the tank. When flow through the tank is not uniform, a portion of the water will not have sufficient contact time. The hydraulic efficiency through a disinfection basin is evaluated with CFD to optimize disinfection dosage requirements.

CFD is the science of predicting fluid flow by solving the governing equations that represent the three fundamental principles of fluid flow (conservation of mass, momentum, and energy). Under specified conditions, the CFD model simulates flow fields and particle transport within the model domain, solving the Reynolds-averaged Navier-Stokes equations that describe the flux of mass and momentum within a fixed domain subject to specified boundary conditions. A finite volume formulation is used where the computational model domain is generated representing the geometry to be simulated, and the domain is divided into discrete volumes called cells (the mesh) where the fundamental fluid flow equations are solved on each of these discrete cells. Integrating these cells over a volume yields the flow field for the computational domain.

The Oakwood CSO RTB CFD model was developed using *Ansys 2022*. This platform includes *SpaceClaim* to develop the model geometry, *Fluent Meshing* for meshing, *Ansys Fluent* for model processing and post-processing, and *CFD-Post* for additional post-processing.

A single-phase (water only), steady-state model was developed for each modeled simulation. The models used the shear stress transport (SST) k - ω viscous model for turbulence where k and ω refer to the turbulent kinetic energy and dissipation rate, respectively. The SST k - ω viscous model contains two transport equations for k and ω with two hybrid equations developed by combining the k - ϵ and k - ω models.

A residence time distribution (RTD) analysis was performed to simulate a tracer test and predict the hydraulic efficiency of the RTB. The Discrete Phase Model (DPM) was used for the RTD analysis where an injection of water particles (tracer) is released at the inlet boundaries and tracked through the fluid domain. The contact time of the tracer is reported at the outlet boundaries to determine the residence time distribution. Industry standard defines the contact time as T_{10} , for drinking water applications and is used for this CSO application as a conservative approach considering public health exposure to the outfall. T_{10} refers to the time at which 10% of the

particles reach the outlet. The hydraulic retention time (HRT) is the theoretical contact time defined as the volume of the contact zone divided by the flow rate. The hydraulic efficiency, or baffle factor, is defined as T_{10} divided by HRT. A higher hydraulic efficiency corresponds to more plug-flow characteristics, which are desirable in a chlorine contact tank to minimize chemical requirements. **Table 3-1** presents guidance on baffle factors provided by the USEPA for various baffling conditions and basins. Using this guideline, a baffle factor of 0.5 could be used for the Oakwood CSO RTB. However, retrofitting the RTB with baffle walls suggests a baffle factor closer to 0.7 could be achieved, which could lead to significantly less chemical usage.

Table 3-1 Baffle Factor Guidelines

Baffling Condition	Baffle Factor	Baffling Description
Unbaffled (mixed flow)	0.1	None, agitated basin, very low length to width ratio, high inlet and outlet flow velocities.
Poor	0.3	Single or multiple unbaffled inlets and outlets, no intra-basin baffles.
Average	0.5	Baffled inlet or outlet with some intra-basin baffles.
Superior	0.7	Perforated inlet baffle, serpentine or perforated intra-basin baffles, outlet weir, or perforated launders.
Perfect (plug flow)	1.0	Very high length to width ratio (pipeline flow), perforated inlet, outlet and intra-basin baffles.

Source: USEPA, March 1991. *Guidance Manual for Compliance with the Filtration and Disinfection Requirements for Public Water Systems Using Surface Water*. Washington, D.C.

Sodium hypochlorite is added to the system downstream of the storm pumps; therefore, the contact time through the RTB starts at the pump discharge in the screening facility, continues through the contact chamber(s) and ends at the effluent finger weirs. Separate models of the screening facility and the contact chamber were developed to evaluate the overall contact time through the RTB. The combined hydraulic efficiency of the screening facility and the contact chamber was defined as:

$$\text{Hydraulic Efficiency} = \text{Baffle Factor} = \frac{T_{10 \text{ screening facility}} + T_{10 \text{ contact chamber}}}{HRT_{\text{screening facility}} + HRT_{\text{contact chamber}}}$$

The screens were modeled as porous zones with a specified pressure drop based on the screen manufacturer's information. The pressure drop modeled assumes 20% blinding since the screens are constantly running and rotating at full speed during operation.

Although the hydraulic capacity of the RTB is 1,660 cfs, the treatment capacity is defined as the 10-year, 24-hour storm predicted to be 1,231 cfs based on the SWMM model as reported in the "Design Storm Event and Facility Flow Rate Summary" memorandum¹; note that at the time of the CFD analysis, the flow rate summary memorandum was considered draft pending GLWA review and will be updated as additional pertinent design criteria are developed. The CFD analysis evaluated the

¹ Appendix A of Draft TM-1 dated February 14, 2023

treatment capacity of 1,231 cfs operating with one screen channel and one contact chamber out of service.

The model geometry (fluid domain) was developed from *Matterport* laser scans of the facility, converted into a *Revit* model, and then imported into the *SpaceClaim* software. A polyhedral hybrid mesh was generated for each model and **Table 3-2** presents the total mesh count for each model.

Table 3-2 Model Mesh Count

Model	Mesh Count
Existing Screening Facility	4.6 million
Existing Contact Chamber Configuration	19.6 million
Proposed Contact Chamber Configuration	14.2 million

4.0 Model Domains and Boundary Conditions

The model domain of the screening facility is shown in **Figure 4-1**. The screen channel and storm pumps assumed to be out of service were located furthest from the contact chamber in operation to present the worst-case scenario for the shortest contact time. Each storm pump in operation was defined as a mass flow inlet with the specified flow rate shown in **Table 4-1**. The three effluent gates to the single contact chamber in operation were defined as pressure outlets. The five screens operating were specified as porous zones with resistance parameters corresponding to a headloss of 14.8 inches (1.2 feet) based on the manufacturer's information. The single-phase (water only) simulation requires an assumed water surface defined as a symmetry boundary, which is an unconstrained boundary that does not impact the flow characteristics below the water surface. The storm pumps discharge above the water surface in the screening facility, therefore, the nappe profile of the pump discharge was assumed based on theoretical calculations of weir flow from a vertical pipe.

The model domain of the existing contact chamber is presented in **Figure 4-2**, which extends from the three inlet gates at the upstream end, through the chamber and the effluent finger weirs to the effluent channel. The influent and effluent weir walls, as well as features such as the intermediate

training walls, the flushing gate walls, floor slopes, structural columns, and scum baffles were included in the model geometry. The model inlet was specified at the three influent gates and defined as a uniform mass flow inlet with equal flow split between the gates. This assumption was validated with the results of the screening facility model.

Figure 4-2
CFD Model Domain of Existing Oakwood CSO RTB Contact Chamber

The proposed baffling configuration for the contact chamber is shown in **Figure 4-3**. This configuration was designed to add minimal headloss compared to the existing configuration and create a serpentine flow path that encourages plug flow. The baffle walls were located in alignment with the existing flushing training walls and support columns to simplify the retrofit construction effort.

Figure 4-3

5.0 Model Results

Velocity contour and direction vector graphics were plotted to demonstrate the flow pattern through each model. High velocity is represented in red and zero velocity is represented in dark blue. The arrows present the direction vector parallel to the cross-section shown and the length of the arrow represents the velocity magnitude. In general, regions of low velocity indicate dead zones, and regions of high velocity suggest where short-circuiting may be occurring. The direction vectors can be used to identify recirculation zones that effectively act as dead zones. All these phenomena (dead zones, recirculation zones, and short-circuiting) are indicative of reduced hydraulic efficiency.

Velocity contours and direction vectors through the screening facility in plan view at mid-depth (Detroit Datum Elevation 107.5) are shown in **Figure 5-1** where the flow path is from bottom to top of the figure. The figure clearly illustrates dead zones in the offline screen channel (left-most screen channel), the overflow channels between the screens, and the contact chamber influent gates that are closed (left-most gates) that reduce the overall hydraulic efficiency. The highest velocities downstream of the screens are the result of the combined flow from two screen channels that is conveyed to the open gates.

Figure 5-1
Screening Facility Velocity Contours and Vectors at Mid-depth

Figure 5-2 presents the velocity contours at the screening facility effluent gates (contact chamber influent gates). Flow split between the gates was predicted to be within +3%/-2% maldistribution validating the assumption of equal flow split between the gates for the existing and proposed contact chamber models.

Figure 5-2
Screening Facility Velocity Contours at the Effluent Gates

The velocity contours and direction vectors for the existing contact chamber are shown in **Figure 5-3** (plan view section at mid-depth, Detroit Datum Elevation 107.5) and **Figure 5-4** (vertical sections through centerline of each influent gate).

As shown in **Figure 5-3**, one large dead zone occurs in the lower-left corner of the basin, likely resulting from the influent gates jetting into the upper-left corner of the basin and causing short-circuiting. **Figure 5-4** shows the highest velocities in the upstream portion of the contact chamber and some short-circuiting over the influent weir wall to the scum baffle. It is apparent that velocities are relatively low through the majority of the contact chamber beyond the influent weir wall. The figures show that flow is relatively uniform beyond the scum baffle approaching the effluent finger weirs.

Figure 5-3
Existing Contact Chamber Velocity Contours and Vectors at Mid-depth

Figure 5-4
Existing Contact Chamber Velocity Contours and Vectors at Vertical Sections

Velocity contours and direction vectors for the proposed baffling modifications are presented in **Figure 5-5** (plan view section at mid-depth, Detroit Datum Elevation 107.5) and **Figure 5-6** (vertical sections through centerline of each influent gate). These figures reveal that the baffling has increased the overall velocity of flow through the basins and created several new dead zones and recirculation regions. These zones occur on the downstream edges of where flow turns around baffle walls, as well as in the corners of the baffle walls upstream of those flow turns. Additionally, the change in the approach conditions at the effluent weirs creates regions of low velocity immediately adjacent to the downstream-most weirs.

Figure 5-5
Proposed Baffled Contact Chamber Velocity Contours and Vectors at Mid-depth

Figure 5-6
Proposed Baffled Contact Chamber Velocity Contours and Vectors at Vertical Sections

Figure 5-7 and **Table 5-1** present the residence time distribution (RTD) results for the existing and proposed baffling configurations. The results predict a modest improvement in hydraulic efficiency for the proposed baffling configuration.

Figure 5-7
Residence Time Distribution

Table 5-1 Residence Time Distribution Results Summary

	HRT	T ₁₀	Baffle Factor
Existing Configuration	9.3 min	5.4 min	0.6
Proposed Configuration	9.3 min	6.8 min	0.7

6.0 Conclusions and Recommendations

The baffle factor of 0.6 for the existing configuration is better than expected and likely attributed to the uniform flow approaching the effluent finger weirs. The baffled configuration demonstrates a modest improvement in hydraulic efficiency with a baffle factor of 0.7. The inefficiencies for the baffled configuration are mainly due to the flow separation around each baffle wall and the short-circuiting to the effluent finger weirs closest to the last pass of the serpentine channel.

A cost to benefit analysis should be completed to evaluate the cost of the retrofit construction for the baffled configuration and the potential chemical savings as a result of the increased hydraulic efficiency.

**Performance parameters commonly used in conventional
conventional analysis of contact basins.**

Parameter	Definition
T	Theoretical detention time.
t_{10} , t_{50} , t_{90}	Time for 10, 50, and 90 percent of the tracer to pass through the reactor.
t_{10}/T	Index of short-circuiting
t_{50}/T	Index of mean detention time
t_{90}/t_{10}	Morril dispersion index, indicates degree of mixing, as t_{90}/t_{10} increases the degree of mixing increases. Likewise, as t_{90}/t_{10} approaches 1.0 plug flow conditions are observed.
d	Dispersion index, indicates degree of tracer dispersion. Under ideal plug flow conditions, the value of d should approach zero. The dispersion index calculation includes all points of the dispersion curve.
L/W	Length to width ratio of flow. Length is the total flow travel in the baffled channel divided by the width of the channel.

2.7 Electrical, TM-6

Oakwood RTB

- Sample pumps
- TRC analyzers
- Replacement of Sodium Hypochlorite FRP storage tanks
- Replace all metering pumps with recirculation pumps, common discharge header and motorized flow control valves
- Replace chemical feed/transfer piping
- Temporary chemical feed system during construction
- Chemical mixer enclosures replacement

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

From: Megan Czach, CDM Smith, Inc.

Date: June 1, 2023

*Subject: TM-6 Electrical Improvements (LEIB-ELEC-1)
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) has been developed to analyze adding reset buttons for each mixer motor on the face of the motor control centers (MCC) and via the SCADA system at the Leib CSO Screening and Disinfection Facility (SFD). Based on the Design Team's evaluations discussed in this TM, the Design Team is recommending the following for adding a physical reset on the face of each MCC bucket and via the SCADA system.

- There are newer soft starters that can be installed to allow for manual and virtual resetting of the starter when it trips. It is recommended to replace the existing soft starters with a new soft starter. This design work will be coordinated with TM-12 Leib CFD Model which is analyzing different mixer technologies and options.

1.0 Introduction and Purpose

The Leib CSO SFD electrical system consists of one DTE utility feed from a 480V, 3-phase, outdoor transformer and one diesel generator feed from a 350kW, 480V, 3-phase stationary generator. The utility feed is connected to a 600-A motor control center, MCC-B, with a 600A sub-feed connection to a 600A automatic transfer switch (ATS). The ATS then feeds a distribution panel with 2 600A breakers, which feeds 2 MCCs, MCC-A and MCC-C. The MCCs feed the various pumps, valves, motors, transformers, and panels at the facility. The facility includes 18 mixers that are powered from all three MCCs.

Presently, when a trip occurs for one of the existing mixer motors, the operators need to call an electrician to reset the mixer units, which is time consuming. There is presently no reset button on the front of the MCC buckets nor is there an option to reset via SCADA.

The purpose of this TM is to summarize the options to address the reset issue. It will look into how to add a physical reset on the face of each MCC bucket for each mixer motor and via the SCADA system.

2.0 Existing System Description and Evaluation

There are presently two Prechlorination Influent Mixers located in the influent channel. Each mixer is 15HP at 460V. There are an additional 16 Disinfection Chamber Mixers which are located in the mixing chambers. There are four mixing chambers with four mixers each. Three mixers can run at a time with one standby in each mixing chamber. Each of these mixers are 15HP at 460V.

The original power configuration for the mixers had across the line starters for each mixer motor. This configuration was updated to the present configuration which has Allen-Bradley soft starters, model type SMC-3, installed in each mixer MCC bucket. The SMC-3 soft starter has a reset button installed on it for resetting, but this requires the operator to call an electrician to come to the building to open the MCC bucket and physically reset the soft starter. The existing soft starter configuration inside the MCC bucket can be seen in **Figure 2-1**.

Figure 2-1
Existing soft starter configuration inside MCC bucket

3.0 System Evaluation

The existing MCCs were installed in 2003 and are in good condition with no visual signs of corrosion or damage. The existing MCCs are Cutler-Hammer, which is now Eaton. Eaton has indicated new buckets would need to be installed into the MCCs with new soft starters for each mixer.

The existing soft starter cannot be connected to a reset button on the front of the MCC even though there is room on the front of the MCC buckets to install one. The existing soft starter also does not have communication capabilities, either hardwired or ethernet/modbus signal, to be reset via SCADA.

4.0 Descriptions of Alternatives

There are newer technology soft starters that can be installed to meet the requirements of physically resetting at the MCC and via the SCADA system.

Each of the existing soft starters can be replaced with a newer version that has both the capability to be reset manually at the MCC and virtually via the SCADA system. The Design Team spoke with both Eaton, the manufacturer of the MCC, and Allen-Bradley, the existing soft starter manufacturer, about their newer products that can be installed to solve the reset issue.

Eaton has a soft starter, model S811+, that can be reset via a keypad installed on the MCC bucket cover and can be reset by the SCADA system via an ethernet/modbus communication cable. A physical reset pushbutton cannot be installed to reset this soft starter. This soft starter will fit in the existing bucket size (18 inches). Eaton recommends ordering new buckets to be installed in the existing MCCs instead of modifying the existing bucket. The face of the keypad for the S811+ soft starter can be seen in **Figure 3-1**.

Figure 3-1
Eaton S811+ Soft Starter Keypad

Allen-Bradley has the SMC Flex soft starter. The SMC Flex can have a manual reset pushbutton or a keypad installed on the front of the MCC, and it has the communication capabilities to be reset via the SCADA system via an ethernet/modbus cable. Allen-Bradley has indicated that this soft starter would need to be mounted in a 24-inch bucket. TM-12 Leib CFD Model is analyzing different technologies and number of mixers. If the option to reduce the number of mixers is the design moving forward, then this soft starter would be an option. The face of the keypad for the SMC Flex soft starter can be seen in **Figure 3-2**.

Figure 3-2
Allen Bradley SMC Flex Soft Starter Keypad

5.0 Alternatives Analysis

Not used.

6.0 Life Cycle Cost Analysis

Not used.

7.0 Summary and Recommendations

The existing starter configuration will not support a manual reset pushbutton on the face of each MCC bucket nor via the SCADA system. There are newer soft starters that can be installed to allow for manual and virtual resetting of the starter when it trips. It is recommended to replace the existing soft starters with a new soft starter.

Different technologies are being investigated as options for an upgrade mixing system in TM-12 Leib CFD Model. The information in this technical memorandum presents a solution if replacement of the mixers is in kind. If a different technology is chosen for design, the electrical group will work with the process mechanical engineers to make sure any starter will have the capabilities to be reset manually at the MCC and virtually on the SCADA system.

2.8 Instrumentation and Control Improvements, TM-7 and TM-21

Oakwood RTB

- Controls/monitoring associate with new loads listed above in electrical
- Float based alarm added on storm pump station intermediate level
- Revise operational strategy (control of storm and sanitary pumps in Ovation) as determined in process evaluation
- Signals to/from new grease lube systems
- Flow meter on each storm pump discharge
- Ovation remote I/O cabinet(s) may needed for integration of additional I/O signals (TBD)
- Replace level sensors for wet well monitoring (total of 8)
- Calibration and scaling of level sensors per City of Detroit Datum and NAVD88
- Addition of process cameras

Leib SDF

- Field instrument calibrations
- Addition of Ovation I/O modules as required
- Ovation programming
- Possible addition of more process cameras
- Replacement of field instruments for disinfection system
- Signals for new equipment

Technical Memorandum

Date: June 1, 2023

*Subject: TM-7 I&C Improvements
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

This technical memorandum (TM) has been developed to address the Instrumentation & Controls (I&C) related improvements at the Oakwood and Leib Combined Sewer Overflow (CSO) facilities identified by the Great Lakes Water Authority (GLWA) and the CS-299 report – OKW-I&C-1A and LEIB-I&C-1A. The memo reviews the existing conditions found at each facility and alternatives to be investigated for instrumentation and control focused items. The three main I&C focused items on this project are the replacement of the level sensors, integration of new Input/Output (I/O) signals into the existing process control systems at each facility, and the addition of process cameras for monitoring process areas at each facility. The following recommendations were generated from this TM:

- Further review the implementation of radar level sensors for wet well monitoring at the Oakwood facility. Further review will include investigation into the ease of maintenance for each type of sensor, installation locations available, and accuracy of the technologies at these locations. GLWA operations has eliminated utilizing submersible pressure transducers due to maintenance concerns. Laser sensors have been eliminated due to classification rating of the sensor not meeting the requirements for the Leib and Oakwood facilities. Review will include sensor redundancy, sensor selection by the operator or the control system, and how the level readings are displayed on the process graphics.
- Integrate new I/O signals into the existing Ovation Distributed Control System (DCS) at Oakwood by utilizing spare I/O points presently available on the existing process controller and extended I/O racks. If spare capacity is not available, identify a location within the electrical room for a new Ovation remote I/O cabinet to be installed.

- Integrate new I/O signals into the future Ovation DCS at Leib by utilizing spare I/O points that will be available within the process controller cabinet. The control system upgrade at Leib is presently under design under a GLWA Contract 2004538.
- Integration of OEM panels equipped with PLC hardware and electrical devices with network communication capability will be through Ethernet utilizing FDI / 3rd party network switches.
- Implement process cameras at Oakwood to aide operations personnel in monitoring the remote facilities. Process cameras hardware and implementation shall be based on GLWA standards provided to the Design Team. Locations for cameras will be reviewed with GLWA during the preliminary and detailed design development.
- Coordinate upgrades to process camera system at Leib with on-going control system upgrade occurring under GLWA Contract 2004538. Additionally, coordinate with GLWA on the need for additional process cameras at the facility. Process cameras hardware and implementation shall be based on GLWA standards provided to the Design Team. Locations for cameras will be reviewed with GLWA during the preliminary and detailed design development.

1.0 Introduction and Purpose

GLWA operates several CSO facilities as part of the overall sewerage conveyance and collection system. GLWA identified improvements to be implemented at the Oakwood CSO Retention Treatment Basin (RTB) and Pump Station and the Leib CSO Screening and Disinfection Facility (SDF). The improvements are intended to improve facility reliability, flexibility, operation, maintenance and safety to support increases in utilization for the two facilities. Future projects will divert flow from the Northwest Interceptor (NWI) to the Oakwood CSO facility, and divert flow from the Meldrum sewer to the Leib SDF.

The focus of this TM is on the I & C related improvements at each facility. The main I&C improvements are related to the influent flow metering and wet well level measurement at Oakwood, the Detroit River Interceptor (DRI) level measurement at Leib, and the integration of process cameras. There are additional process or system improvements that will require I&C modifications such as chemical disinfection, mechanical screen replacements, and overall facility sequence of operations (control narrative) modifications. The purpose of this TM is to summarize the I&C improvements, identify existing field conditions, and to recommend alternatives where appropriate.

2.0 Existing System Description and Conditions

2.1 Oakwood CSO RTB and Pump Station

2.1.1 Level Instrumentation

The Oakwood CSO has two wet wells for incoming sewage flow – East and West. When the new facility was built, each wet well had redundant bubbler systems for level monitoring on the

upstream and downstream sides of the screen (**Figure 2-1 and 2-2**). Each level was monitored by dual pressure sensors located in the Sanitary Pump Station (SPS) basement.

East Wet well

Upstream – LT804017A/B

Downstream – LT804018A/B

West Wet well

Upstream – LT804015A/B

Downstream – LT804016A/B

Figure 2-1

Oakwood CSO Redundant Bubbler Systems for Wet Well Level Monitoring

Components of the bubbler systems have failed over time and the location of the air piping within the wet well has made access for repair difficult. GLWA has installed alternate level sensors over time, with the present setup using ultrasonic and radar level transmitters to measure the levels in the wet wells. Due to the enclosed nature of the wet well, and the sanitary pumps, there have been issues with the ultrasonic sensors giving false readings. Radar units were added to provide backup level measurements and are now used as the main signal by operators and the control system.

Figure 2-2
Wet Well Level Sensors at Oakwood SPS

There are additional level sensors in the RTB side of the Oakwood facility for monitoring levels at the screens, inside the basins, surge chamber, and NWI connection. These sensors were calibrated and survey elevations were taken to provide level readings in true elevation in the control system.

Most of the instrumentation signals at Oakwood connect to the Ovation control system, except for the gas detection equipment which connects to the master gas system panel. The Ovation system is divided between the main panel at the SPS located in the front of the facility and a remote I/O panel in the RTB located by the screening equipment.

2.1.2 Control System Architecture

The existing Oakwood process control system utilizes an Emerson Ovation DCS platform with process controllers, database server, and operator workstations. A redundant process controller cabinet with redundant OCR1100 controllers is installed in the Instrumentation and Communication Room, along with an extended I/O cabinet (**Figure 2-3**). An Ovation remote I/O cabinet, located in the Electrical Room of the Screening Facility (**Figure 2-4**), integrates I/O from the screening process and CSO basins into the DCS. A control room located in the pump station is equipped with an Ovation database server, an operator workstation, and a large wall-mounted display for viewing the Human-machine interface (HMI) graphics (**Figure 2-5**).

Figure 2-3
Ovation Controller Cabinet, Extended I/O Cabinet, and UPS Cabinet in the Instrumentation and Communication Room

Figure 2-4
Ovation Remote I/O Cabinet in Screening Facility Electrical Room

Figure 2-5
Control Room for Oakwood CSO Facility

2.1.3 Process Cameras

There are no process cameras installed at the Oakwood CSO facility presently.

2.2 Leib SDF

2.2.1 Level Instrumentation

The Leib SDF influent is from two sewer lines under Mt. Elliot Street. There are existing level and Accusonic flow sensors inside the sewers upstream of the facility, as well as ultrasonic level sensors in the influent channel and disinfection chamber within the facility. Additional level and flow sensors are located at remote monitoring points on the “Toward Treatment Sewer to DRI” and on the Mt. Elliot sewer towards the outfall at the Detroit River. These remote sensors presently communicate with the Leib facility via radio links.

GLWA has an active design-build project to upgrade the Control Systems at the Leib, St. Aubin and Seven Mile facilities. This project is slated to replace the PLC and HMI equipment at the Leib facility, in addition to control panel modifications and instrument replacement. The remote I&C panels located outside of the Leib facility (CP-2, CP-3, CP-4) are also being replaced under the project and their radio communication back to the Leib facility is to be replaced with a secure cellular connection. This project is anticipated to begin construction towards then end of the year and all equipment slated for replacement will be in place by the time the design is complete.

The DRI Level sensor (LIT-3) located at the CP-3 remote panel on Jefferson Avenue is listed to be replaced under the Control Systems Upgrade project. The sensor is being replaced by the Control Systems Upgrade project (GLWA Contract # 2004538). Based on the CDM Team’s review of the 60% design submittal documents, the CDM Team’s work does not include evaluation of the level sensor. The CDM Team will use the associated signal as-is as an input to the operational strategy and associated facility control. LIT-3 will not be .

2.2.2 Control System Architecture

A process control system upgrade is presently being designed under a separate capital improvement project (CIP) to replace the existing Allen-Bradley PLC / HMI based control system presently being utilized (**Figure 2-6**). The existing Allen-Bradley platform utilizes obsolete Allen-Bradley PLC hardware installed, along with Rockwell HMI software for viewing HMI graphics (**Figure 2-7**). Under this separate CIP, the process control system will be migrated to a distributed control system (DCS) architecture utilizing Emerson Ovation hardware. A new Ovation controller cabinet is planned for installation into the existing Electrical Room. The existing PLC panel, Panel CP-1A (**Figure 2-8**), will be converted to a Marshalling Panel at an intermediate termination location between field devices and the Ovation I/O modules. The Ovation controller will contain redundant process controllers communicating with redundant Ethernet Root Switches. A new database server and two operation workstations will be provided with dual monitors to enable local monitoring through HMI graphics.

Figure 2-6
Existing Rockwell HMI System in Office

Figure2-7
Existing Allen-Bradley PLC Processor Racks in Office

Figure 2-8
Existing Control Panel CP-1A housing Allen-Bradley PLC hardware. CP-1A will be converted to a Marshalling Cabinet under separate CIP.

2.2.3 Process Cameras

The Leib SDF facility has existing process cameras that overlook the screening channels. Coordination with GLWA Contract 2004538 to identify improvements to the network infrastructure and existing process cameras will be performed at the design documents are developed further on the control system upgrade project.

3.0 System Evaluation

3.1 Oakwood CSO RTB & SPS Level Sensors

The physical design and orientation of the wet well at the Oakwood facility provides some challenges for level measurement. Due to past experience with contact type technologies (bubbler) and the difficulty of maintaining them inside the wet well, alternative non-contact solutions need to be investigated. Based on the critical nature of the wet well level measurements and their impact on the operation of the SPS and RTB, redundant solutions are recommended.

GLWA's pilot testing of different non-contact technologies in the wet well showed that radar sensors provided better reliability and accuracy over a wide range of elevations. Similar results were gained with ultrasonic sensors after they were tuned and adjusted for the shape and configuration of the wet wells. Contact-type sensors such as hydrostatic were initially considered but are not being pursued due to maintenance concerns with equipment located inside the wet well. Investigation of alternative technologies such as laser-based level sensors was performed. Laser level sensors provide accuracy and immunity from noise but are susceptible to fog/mist. The main reason they were not considered was the lack of certification for use in classified environments.

Another consideration for the wet well monitoring is the location of the sensors, keeping in mind future maintenance needs. Due to the location of the opening above the wet well, the present downstream sensors are located below the wet well ceiling slab and are difficult to access. One alternative is to locate the sensor below the access hatches for the sanitary pumps (**Figure 2-9**). The use of a "swing-arm" type mounting system, similar to the one installed at the Puritan Fenkell facility (**Figure 2-10**), would be part of the installation design. This configuration allows for the sensor to be moved out of the wet well for maintenance or for access to the hatch.

Figure 2-9
Oakwood SPS Wet Well Level Sensor Locations

Figure 2-10
Level Sensor Swing-arm Mounting Assembly

3.2 Leib SDF

The level sensors at the Leib facility are planned to be replaced under the Control System Upgrade project. The remote sites tied to Leib are also planned for upgrade under that project. Level measurement will be coordinated with that project to identify the proper instrument to be used.

4.0 Description of Alternatives

4.1 Level Sensors Alternatives

The two main categories of level sensing technologies are contact and non-contact. Contact type sensors are in direct contact with the process fluid. Sensors can be located inside a vessel (submersible/hydrostatic), or connected via a diaphragm close to the bottom of a vessel (pressure sensor). Non-contact sensors are not in direct contact with the process fluid – radar, ultrasonic, and laser are most common types. These are located at the top of a vessel, outside of any flow path. Newer model can also be mounted on the outside of an enclosed vessel, which is advantageous for chemical level monitoring.

The advantages to non-contact technologies are longer sensor life since they are out of any corrosive/harsh environments, and easier maintenance with sensors normally located close to access hatches or on top of tanks. Replacement of a failed sensors is made easier without confined space access. Disadvantages include higher costs than contact type sensors, and susceptibility to interference (fog, mist, etc.).

4.2 Integration of New I/O Signals

For the integration of new I/O signals into the existing Ovation DCS system at Oakwood and future Ovation DCS system at Leib, there are two options:

- Option 1 - Utilize spare I/O points and install additional Ovation Cabinets if necessary to incorporate the I/O signals from new field instrumentation and process equipment.
- Option 2 - Utilize Rockwell PLC hardware for interfacing with new I/O signals and digitally communicate the signals into the Ovation DCS systems at each facility.

Rockwell hardware would utilize the ControlLogix or CompactLogix platform that have been adopted by GLWA as alternatives to Emerson Ovation. A PLC panel equipped with power supplies, I/O modules, control processor, and communication module would provide the interface to hardwired I/O signals from field instrumentation and process equipment. Communication to the Emerson Ovation DCS would be implemented through the one of two methods:

- Ethernet communication from PLC rack to third-party network switch provided on Ovation system to communicate to 3rd party (PLC) devices. The Ethernet/IP driver within the Ovation process controller would be utilized to communicate to the PLC through the 3rd party network switch and router.

- Install dedicated Ethernet Link Controller (ELC) module in the Ovation Controller or I/O panel to communicate with the PLC over Ethernet.

4.3 Process Cameras

GLWA provided standard guidelines and design drawings for the process camera system. No alternatives were reviewed.

5.0 Alternative Analysis

5.1 Level Sensors

GLWA uses various types of level sensor throughout their facilities and system. Selection of contact vs. non-contact is on a case-by-case basis per the application. For the wet wells at Oakwood, past experience with the bubbler system and ultrasonic sensors initially steered the decision for new sensors towards radar and laser units. Maintenance of any type of submerged sensor is difficult, requiring draining the wet well and confined space. Discussions with GLWA operations and maintenance staff confirmed that contact type sensors were not preferred.

Ultrasonic sensors were installed in the wet wells at one point as replacements for the failed bubblers, but those exhibited spikes in level readings making them unreliable. Tuning and adjustment of the ultrasonic sensors has improved their performance, making them a suitable alternative for the backup level sensor role. The radar sensors piloted by GLWA have been more reliable over time and are the main alternative for new sensor technology. Laser level sensors have not been used at GLWA and their lack of certification for the environment has dropped them out of consideration.

5.2 Integration of I/O Signals

Option 1, utilizing Ovation spare I/O points and if necessary installing an additional remote I/O cabinet provides the most cost effective and efficient option for these facilities. Both facilities will utilize the Ovation hardware and offer spare points to integrate future I/O points. All new I/O points at Leib are anticipated to be wired to spare I/O channels and new I/O modules installed in the Ovation Controller Cabinet to be installed under the separate GLWA Contract # 2004538. At Oakwood, limited spare points are available for new I/O signals. A new Ovation remote I/O cabinet may be needed to integrate the new signals from the anticipated field instrumentation and process equipment for disinfection. This cabinet would be located in the Electrical Room of the Pump Station due to the lack of space to install a new I/O cabinet in the Instrumentation and Communications Room.

Utilization of Rockwell hardware at these facilities as Option 2 was eliminated due to both facilities utilizing Ovation DCS hardware, along with eliminating the need for a PLC system integrator to provide PLC logic development and I/O mapping to the Ovation DCS. If PLC hardware were utilized, testing and commissioning of the system would include verification and checkout of the PLC logic and additional verification of data mapping between the PLC and Ovation DCS.

5.3 Process Cameras

No alternatives were developed or analyzed; design will be based on GLWA standards.

6.0 Summary, Recommendations and Key Decisions

6.1 Level Sensors

Non-contact level sensors will be utilized for the level measurement of the wet wells at Oakwood. Due to the crucial nature of the wet well level measurement in the overall facility's operation, the recommendation is to utilize redundant level sensors on the upstream and downstream sides of the wet well screens. Control logic will be updated for locations where multiple level sensors are utilized to enable GLWA to select a preferred sensor, highest level from multiple sensors, or an average value for the control variable. Refer to TM-15 for details on the control strategy to be implemented with the level sensors.

6.2 Integration of I/O Signals

New instrumentation and process equipment for both Leib and Oakwood will be integrated into the Ovation DCS Platform by utilizing spare I/O points and installation of additional Ovation I/O modules. For Oakwood, if the new I/O signals exceed the limited number of spare channels available, a new Ovation remote I/O cabinet will be installed. This remote I/O cabinet will most likely be located in the Electrical Room, due to a lack of space in the Instrumentation and Communication Room. For Leib, new instrumentation and equipment I/O signals will be integrated into the future Ovation Controller Cabinet to be installed under a GLWA Contract 2004538. Spare capacity is anticipated to cover all new I/O signals for the site. This includes utilization of spare channels on installed I/O modules, along with the installation of new I/O modules within the existing cabinet.

For OEM and 3rd party equipment equipped with PLC or network communications, including packaged screening systems and soft starters for pumps, an Ethernet connection will be provided to connect to the existing Foreign Device Interface (FDI) or 3rd party network switches. The Emerson process controllers communicate to the FDI network switches through the Root Switches and routers.

6.3 Process Camera System

Per GLWA's request in the RFP, new process cameras will be installed at each facility to monitor process area equipment operation. The process camera system will be based upon GLWA standards provided to the Design Team. In compliance with GLWA standard, the following key design items are noted:

- Specified hardware will be Avigilon for cameras and Razberi EndpointDefender for network endpoint appliance with no substitutions permitted.
- Design drawing package for process camera system will include the following:

- Plan view of the camera, cone of view, network device, and server locations. Conduit, wiring, grounding, and viewing PC/monitor information will be provided with design documents and referenced to plan view if not included on plan view drawing.
- Camera panel and installation mounting details based on GLWA standard details.
- Riser diagram for process camera system hardware with port numbers identified.
- Schedules for cameras, conduits, devices, and power circuits with tag information.
- Coordination meeting with GLWA IT for determination and identification of all server, IP, and camera, and switch addresses.
- Coordination with GLWA's security system provider, D/A Central, for integration into the existing system.

6.4 Key Decisions

- Contact type level sensors will not be considered for installation at Oakwood.
- Upstream and Downstream wet well channels will both have redundant level sensors at Oakwood.
- Leib DRI Level sensor (LIT3) is being replaced by GLWA Contract 2004538.
- Emerson Ovation hardware will be utilized for the interface to hardwired I/O signals by utilizing existing spare I/O points on installed modules, adding I/O modules to existing Ovation cabinets, or adding additional Ovation I/O cabinets.

7.0 Next Steps

There are several areas that require additional investigation and selection of alternatives for other TMs to progress the process control system design.

- Redundancy for wet well level sensors
 - Level measurement criticality for facility operation
 - Sensor redundancy & failover strategies
 - Long-term maintenance costs
 - Ease of maintenance (sensor mounting locations / clearances)
- Integration of I/O Signals into Ovation DCS Platform
 - Finalize selection of disinfection equipment and develop P&IDs.

TM-7 I&C Improvements

June 1, 2023

Page 15

- Finalize selection of screen systems and develop P&IDs.
- Identify I/O signals available (spare points / equipment to be removed / etc.).
- Identify need for new remote I/O cabinet based on point count.
- Identify OEM and 3rd party devices to be connected via Ethernet to the Ovation DCS.
- Coordination I/O requirements with control system upgrade at Leib.
- Process Control Functionality
 - Develop automatic control strategies once final disinfection equipment and methods for operation are finalized in TMs.
- Process Camera System
 - Identify process areas and locations GLWA operations wants to visually monitor through process cameras.
 - Identify locations for local hardware (switches / server / cabinet) associated with process cameras as Oakwood and Leib.
 - Engage DA Central to discuss the system design, integration, and establish an allowance to be included in the bid package.

Technical Memorandum

*Subject: TM-21 Basin Influent Flow Metering
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

The existing Teledyne ISCO Pro20 hot tap insertion pulse Doppler acoustic flow meters (Existing Meters) at the Oakwood Combined Sewer Overflow (CSO) Retention Treatment Basin (RTB) and Pump Station have reached the end of their expected life cycle. The Great Lakes Water Authority (GLWA) has appointed the Design Team to evaluate alternatives and design a solution to provide reliable Oakwood CSO RTB and Pump Station influent flow metering. The design is to include a primary means of metering the influent flow as well as a backup flow measurement. This technical memorandum (TM) reviews the existing flow metering system conditions at the Oakwood CSO RTB and Pump Station facility and analyzes potential alternatives to fulfill the Oakwood CSO RTB influent flow rate metering needs.

Review of the recorded influent flow rate data found that the Existing Meters no longer produce usable flow rate data and need to be replaced. The following improvements are recommended to provide reliable influent flow metering and a backup flow measurement at the Oakwood CSO RTB and Pump Station.

- An advanced Doppler insertion meter is to be installed as a replacement for each of eight Existing Meters to measure the Oakwood CSO RTB influent flow rate through metering along the storm pump discharge piping.
- A method of estimating the Oakwood CSO RTB influent flow rate using storm wet well level data from Ovation, variable frequency drive (VFD) data from Ovation, storm pump curves, and pump run time to be programmed as a backup to the new insertion meters. This method of estimating the Oakwood CSO RTB influent flow rate could be used to check the accuracy of

the flow meters over time and will be available if the flow meters go out-of-service during a wet weather event.

- Future consideration for installing a flow meter in the influent sewer upstream of the storm wet well to measure the Oakwood CSO RTB influent flow rate.

1.0 Introduction and Purpose

The existing flow meters at the Oakwood CSO RTB have reached the end of their expected life cycle and need rehabilitation or replacement. Analysis of the data produced by these flow meters has shown that they no longer provide accurate or reliable measurements of the flow through the storm pump discharge piping (Section 3.1).

Accurate measurement of flow through the storm pump discharge piping is important for several reasons:

- Determination of the chlorine feed rate to each pump
- Determination of the Oakwood CSO RTB influent flow rate for use in chlorine contact time (CT) calculation
- Analysis of storm pump behavior and performance
- Accurate Oakwood CSO RTB influent flow rate reporting

The Design Team investigated flow meter alternatives that provide accuracy and reliability in measuring Oakwood CSO RTB influent flow rate (Section 4.0). A brief overview of the alternatives considered includes:

- Rehabilitate the existing flow meters
- Replace the existing flow meters with latest version of the same make and model flow meter
- Replace the existing flow meters with an alternative metering technology
 - At the same locations as the existing flow meters
 - Insertion flow meters
 - Spool piece / In-line magmeters
 - At a different location along the storm pump discharge piping
 - Level sensors
 - Ultrasonic meters
 - Spool piece / In-line magmeters

- At a different location upstream of the Oakwood CSO RTB and Pump Station Storm Wet Wells
 - Ultrasonic meter

2.0 Existing System Description

As described in the 2012 CS-1364 Oakwood CSO Control Facility and Pump Station Operations and Maintenance Overview Manual, the Oakwood CSO RTB and Pump Station utilizes eight storm pumps to pump combined stormwater/wastewater up from the facility's storm wet wells to its Screen Facility and CSO Basins. Storm pump Nos. 1 and 2 are controlled by VFDs to allow pumping rates that vary from approximately 97 MGD down to 40 MGD at minimum speed. Storm pump Nos. 5 and 6 are also controlled by VFDs to vary their pumping rates from 178 MGD down to 72 MGD. The VFD equipped pumps are intended to allow the facility to match the incoming flow rates and maintain storm wet well levels. The remaining Storm Pumps, Nos. 3, 4, 7, and 8 are fixed speed pumps equipped with soft starters. These four storm pumps are intended for use during large wet weather events and have fixed pumping capacities of 178 MGD each.

Flow rates through all eight storm pumps are measured via the Existing Meters. The Existing Meters are placed within the storm pump discharge piping. **Figure 2-1** shows the associated pump number and the manhole (MH) yard vault of all eight Existing Meters, with color coding to show analogous MH yard vault locations. Existing Meters for storm pump nos. 3 & 5 and nos. 4 & 6 share common MH yard vaults. Existing Meters for Storm Pump nos. 1 through 6 are all located on the longest section of straight pipe in the discharge piping. Existing Meters for storm pump nos. 7 and 8 are located on the downstream horizontal run of the discharge pipes.

The Existing Meters are connected to their respective process through two-inch hot tap connections on the storm pump discharge piping through a two-inch flange and ball valve mounted on the pump discharge piping.

The electronics for each of these units are contained in NEMA 4X type enclosures. The Existing Meters operate using $115 \pm 10\%$ VAC, 60 Hz power. The signal input for the electronics is from a hot tap insertion transducer, with a 4-20 mADC input signal. The electronic units have a four line by 16-character display operating off an internal alkaline battery providing 24VDC, 13Ah @ 75 °F.

The Existing Meters are pulse Doppler acoustic flow meters with range gating signal processing. The Existing Meters use a transducer assembly with four individual velocity transducers using piezoelectric ceramics for emitting and receiving 1.23 MHz acoustic signals to measure velocity throughout the depth of flow. Each transducer has an operating temperature of 23 to 95 °F and is housed in a plastic transducer assembly on a corrosion resistant stainless-steel stem that can withstand a static pressure of 250 psi.

Each Existing Meter has a manufacturer stated accuracy of $\pm 2.5\%$ of reading and ± 0.01 ft/s times the area.

Figure 2-1
Oakwood Storm Pump Meter Pit Location

3.0 System Evaluation

Recorded flow meter data was collected and reviewed to evaluate the accuracy of the Existing Meters. Pump run time data was also collected and reviewed to supplement the evaluation. The analysis is described in detail in the following section.

3.1 Ovation Data Review

Recorded Ovation data from the eight storm pumps and the Existing Meters spanning from September 1, 2019 to November 15, 2022 was collected and reviewed. **Table 3-1** shows the point names and a description of the data gathered from Ovation for this analysis.

Table 3-1 Oakwood Ovation Data Gathered

Ovation Point Name	Point Description
N804001R.UNIT0@OKW	Oakwood Storm Pump 1 Running
N804002R.UNIT0@OKW	Oakwood Storm Pump 2 Running

OKW-EFFLUENT-FLOW.UNIT0@OKW	Oakwood Effluent Flow

Flow rate data were reviewed to identify missing or erroneously low flow rates (dropouts) and peak recorded flow rates. The peak flow rate data was compared to the nominal pump capacity tributary to each meter. Data were reviewed to answer the following questions shown in **Table 3-2**.

Table 3-2 Data Review Questions

Question	Rationale
Did the meter record flow rate data when the pump was ON?	It is expected that the meter records flow rate any time the respective storm pump is running.
Was there any significant flow recorded when the pump was ON?	The storm pumps have capacities of 40 to 178 MGD. The metered flow rate must be of the appropriate order of magnitude to be reasonable.
Was the flow rate data ever reasonable?	A meter that never recorded a reasonable magnitude flow rate showed clear issues.
Did the meter consistently provide reasonable flow rates?	A meter that did not consistently record a reasonable magnitude flow rate showed clear issues.

Table 3-3 provides a summary of the data and responses to the data review questions. The pump color coding matches what is shown in **Figure 2-1** to indicate which Existing Meters share similar MH yard vault locations.

A detailed review of seven storm events was included in this analysis. These storm events were chosen to show storm pump performance for events that differ in size, number of pumps operating, and date of the event. The complete analysis and inclusion of these seven storm events as examples show the overall unreliability of the Existing Meters.

Table 3-3 Oakwood Flow Meter Analysis Summary

Parameter	Oakwood Facility		Small VFD		Large VFD		Constant Speed			
	Influent	Effluent	Pump 1	Pump 2	Pump 5	Pump 6	Pump 3	Pump 4	Pump 7	Pump 8
Nominal Pump Capacity (MGD)	-	-	97	97	178	178	178	178	178	178
Nominal Pump Minimum (MGD)	-	-	40	40	72	72	-	-	-	-
Peak Recorded Flow Rate (MGD)	-	-	100	< 1	< 1	68	100	< 1	100	100
Did Flow Meter Always Record Data When Pump Ran?	-	-	NO	NO	YES	YES	YES	YES	YES	NO
Was Any Significant Flow Recorded When Pump On?	-	-	YES	NO	NO	YES	YES	NO	YES	YES
Was Metered Flow Rate Ever Reasonable?	-	-	YES	NO	NO	NO	NO	NO	NO	NO
Storm Events (Peak Flow Rates in MGD):										
September 12, 2019	168	213	0	N/A	N/A	42	100	< 1	10	N/A
August 2, 2020	259	582	89	< 1	N/A	68	N/A	< 1	100	N/A
March 26, 2021	155	187	0	N/A	N/A	28	100	< 1	100	84
June 25, 2021	162	265	0	< 1	N/A	29	100	< 1	100	96
July 25, 2021	226	394	0	< 1	N/A	29	100	< 1	100	100
September 2, 2022	5	0	0	N/A	< 1	N/A	1.5	N/A	5	N/A
October 31, 2022	23	0	23	N/A	< 1	N/A	N/A	N/A	N/A	N/A
Did Meter Consistently Provide Reasonable Flow Rates?	-	-	NO	NO	NO	NO	NO	NO	NO	NO

Notes for storm event peak flow rate data:
0 MGD = Pump On, but No Flow Recorded
< 1 MGD = Pump On, and Less than 1 MGD Recorded
N/A = Pump Did Not Turn On

Existing Meter for Storm Pump No. 1 did record a reasonable peak (100 MGD compared to the nominal pump capacity of 97 MGD) during the period reviewed and for one of the seven storm events reviewed in detail (August 2, 2020). However, this flow meter did not record any flow on multiple occasions when the pump was indicated to be 'Running,' including six of the seven storm events reviewed in detail. This flow meter also recorded a peak flow rate outside of its operating range on at least one occasion (October 31, 2022).

Existing Meter for Storm Pump no. 2 never recorded any significant flow over the period reviewed. The metered flow rate from this flow meter was never reasonable as the peak recorded flow rate was less than 1 MGD. There were also instances when this flow meter did not record any flow while the pump was indicated as 'Running.'

Existing Meter for Storm Pump no. 3 always recorded flow while the pump was 'Running'. However, the recorded flow from this flow meter was never considered reasonable as the peak flow was well below the nominal pump capacity for this constant speed pump.

Existing Meter for Storm Pump no. 4 did not record a flow rate greater than 1 MGD, which is not considered reasonable given its nominal pump capacity.

Existing Meter for Storm Pump no. 5 did not record a flow rate greater than 1 MGD, which is not considered reasonable given its nominal pump capacity.

Existing Meter for Storm Pump no. 6 always recorded flow rate data when the storm pump was 'Running', and always recorded a significant flow rate (i.e., greater than 1 MGD). However, the peak recorded flow rate at this meter was 68 MGD which is only slightly lower than what would be

expected for the minimum flow rate through this pump. However, the recorded data shows multiple storm events where this flow meter is considered unreasonable.

Existing Meter for Storm Pump no. 7 always recorded a significant flow rate when the pump was 'Running'. This meter had a peak of 100 MGD, which is significantly lower than the expected nominal pump capacity of 178 MGD for this constant speed pump. This meter also recorded a peak flow rate much lower than 100 MGD for two of the seven storm events reviewed in detail (September 12, 2019 and September 2, 2022).

Existing Meter for Storm Pump no. 8 did not record any flow on multiple occasions when the pump was indicated to be 'Running'. This flow meter also did not ever record a peak flow rate that was considered reasonable for this constant speed pump.

In summary, the data analysis indicates that all eight Existing Meters failed at least one of the tests developed to check the recorded data and are unfit to record good and useful data for the Oakwood CSO RTB and Pump Station.

There was some concern that the meter location along the storm pump discharge piping was a factor in the performance of the Existing Meters. The meter location appears to play no role in the performance of the flow meters. Storm pump flow meter no. 1 through no. 6, which are at analogous locations along the discharge piping, do not appear to provide data that is any better or worse than Storm Pump meters no. 7 and no. 8.

The analysis also looked at select storm events to notice any patterns in how the Storm Pumps operated or how the flow rate data gathered may have changed over time. Observing the data across the storm events, it appears that there is no correlation temporally or based on storm size to the quality of the data that the storm pump meters produce.

3.2 Meter Maintenance/Inspection

A site visit to the Oakwood CSO RTB and Pump Station was completed to assess the condition of the Existing Meters. The goal of the visit was to determine if the erroneous flow rate readings were due to the condition of the Existing Meters or an issue with the metering technology.

The site visit was conducted on December 21, 2022 in conjunction with routine meter maintenance being performed by PCI, under a separate contract with GLWA. During this site visit, the hot tap insertion probes were pulled from the MH yard vaults, inspected, and cleaned. The Design Team was able to observe this process and collect qualitative data about the condition of the insertion probes.

No solids build-up was observed on any of the meter probes. The PCI technician had noted that these hot tap insertion probes typically come out dry and clean when inspected at this installation location during dry weather when the storm pumps were not in service. The meter probes have not been previously observed with any material caked on that would adversely affect the meter's ability to function as intended.

Table 3-4 provides images of the meter probe tips as observed before cleaning on the day of the site visit. Meter probes 1 and 2 appeared to be in the best condition. Meter probes 1 and 2 service the small, 97 MGD, storm pumps so may have received less wear. Meter probes 3, 5, 6, 7, and 8 all appeared to have varying levels of fading and/or signs of abrasion across the surface of the probe. The wear on these probes could have a negative effect on the meter performance. Meter probe 4 was missing from the MH yard vault and could not be observed.

PCI had noted during the site visit that meter probe 2 was not working properly as the meter was not displaying flow data. The absence of meter readings was said to most likely be attributed to a disconnection in the meter electronics.

Table 3-4 Images of the Hot Tap Meter Insertion Probes for All Eight Storm Discharge Pipes

	
Meter Probe 1	Meter Probe 2
	N/A Probe Missing from MH Yard Vault
Meter Probe 3	Meter Probe 4

Table 3-4 Images of the Hot Tap Meter Insertion Probes for All Eight Storm Discharge Pipes cont.

	
Meter Probe 5	Meter Probe 6
	
Meter Probe 7	Meter Probe 8

A field report written by PCI in 2018 summarized a series of site visits in which troubleshooting was performed for all eight flow meters. The report summary noted that the Existing Meters for Storm Pump nos. 1, 7, and 8 were tested and found to be operational with no changes necessary. Existing Meters for Storm Pump nos. 2 and 3 were operational after the transmitter was reconfigured. The Existing Meter for Storm Pump no. 6 was operational after the transmitter was reconfigured and the probe was adjusted. The Existing Meter for Storm Pump no. 5 could not be tested as the pump was being repaired at the time of the visit, however the transmitter was tested and operational. The Existing Meter for Storm Pump no. 4 was not operational, and the transmitter was removed and sent back to Teledyne ISCO to be diagnosed and repaired. This evaluation by PCI was submitted before the period of data that was analyzed in the following section. The field report summary shows that several flow meters were not operational in 2018 but were returned to an operation status. However, the PCI procedures are completed during dry weather and “operational” is an indication that the meter provides a signal, not that the signal is accurate.

Since the 2018 report, PCI has performed semi-annual to quarterly preventative maintenance and calibration on the Existing Meters. The preventative maintenance has shown issues with the meter

probes and transmitters. As these meters are no longer supported by the manufacturer, it is difficult to restore these meters to a fully-functioning condition.

4.0 Description of Alternatives

The Design Team explored various alternatives to address the Oakwood CSO RTB influent flow rate metering issues. Based on the Ovation data analysis and the condition assessment of the meter it was determined that the Existing Meters needed to be replaced with new meters.

Rehabilitation or replacement in-kind of the Existing Meters were considered as alternatives. These options were discarded as the existing metering technology, the Pro20 ADFM Velocity Profiling Insertion Flowmeter manufactured by Teledyne ISCO, is a discontinued product and is no longer supported. As such, rehabilitation and replacement in-kind are not viable options. Additionally, the GLWA CSO Improvements Project Guiding Principles advises against replacing equipment in-kind, but seeking solutions that improve performance and reduce maintenance.

The Design Team explored multiple alternatives to improve Oakwood CSO RTB influent flow rate metering. The Design Team explored options that used a variety of technologies and techniques to measure or estimate the flow through the discharge piping, at the Storm Pumps, and in the influent sewer. The methodologies discussed include the following:

- New insertion meters placed in the Existing Meter pits (Section 4.1)
- Level sensors located at the storm discharge pipes in the Screen Facility (Section 4.2)
- External and internal ultrasonic flow meters on the vertical discharge piping in the Screen Facility (Section 4.3 and 4.4)
- Spool piece / in-line magmeters installed in either the vertical discharge piping in the Screen Chambers or the horizontal discharge piping between the storm pumps and the Screen Facility (Section 4.5)
- Calculation of storm pump flow using monitored pump activity and measured storm wet well levels (Section 4.6)
- Metering of flow upstream of the storm wet wells to measure incoming flow (Section 4.7)

4.1 Insertion Meter

For this alternative eight new insertion meters would re-use the existing MH yard vaults and hot tap sleeves, currently occupied by the Existing Meter probes, to measure the flow rate in all eight storm discharge pipes. Implementing new insertion meters would have minimal construction implications, and there would also be minimal change in procedure to the current meter servicing process.

An insertion meter would function similarly to the existing flow meters. Insertion magmeters and an ultrasonic cross correlation meters were evaluated.

4.1.1 Insertion Magmeter

An insertion magmeter works to measure flow rate by utilizing Faraday's law of induction. Magmeters operate based on the principle that a voltage is induced in an electrical conductor moving through a magnetic field, where the conductor is the flowing water being measured. The magnitude of the induced voltage is proportional to the velocity of the conductor. Electrodes measure the induced voltage on opposite sides of the sensor. The voltage readings are averaged to obtain a velocity which is then converted to a flow rate by using the known cross-sectional area of the pipe. In the case of an insertion magmeter, the electrodes are housed in a probe that is inserted into the pipe.

4.1.2 Advanced Doppler Insertion Meter

An advanced Doppler insertion meter calculates the flow rate through a measurement of the flow velocity. The flow velocity determination method is based on the ultrasonic reflection principle. The reflecting particles contained within the medium (e.g., debris or gas bubbles) are scanned using an ultrasonic impulse transmitted in a defined angle and are saved as an image. The positions of the reflecting particles are determined by correlating saved signals. The particles can be found in different positions in sequential images since they move with the medium. Considering the beam angle, it is possible to directly convert the shift of the particles into their velocity which is equal to the flow velocity of the medium.

Figure 4-1 shows a diagram of an ultrasonic cross correlation flow measurement insertion meter probe.

Figure 4-1
Ultrasonic Cross Correlation Flow Measurement Insertion Meter Probe

4.2 Level Sensor

This alternative would implement eight level sensors that would obtain a level measurement over the rim of each discharge pipe. The level sensor alternative includes a down looker level sensor and a pressure sensor.

A level sensor would be used in conjunction with a hydraulic calculation to estimate the effluent flow rate out of each discharge pipe. While a level sensor would only measure a depth, an equation, such as the weir equation, would be used to convert the depth into a flow rate. A specific formula would need to be developed for both the 54-inch and 72-inch discharge pipe sizes.

4.2.1 Down Looker Level Sensor

The down looker level sensors would be mounted to the ceiling of the Screen Facility and out of the way of any flow. The location of these level sensors would make them relatively easy to install and maintain. Down looker level sensors are available with electronics using ultrasonic signals, radar signals, and lasers.

A level sensor would be placed over the rim of the vertical discharge piping in the Screen Facility to read the water level over the rim.

4.2.2 Pressure Sensor

The pressure sensors would be installed to the pipe wall within the vertical discharge piping in the Screen Facility. The pressure sensor would sit in the flow of the discharge pipe during storm pump use.

A pressure sensor measures the water pressure above the sensor and translates this measurement into a depth. A comparison of the depth of the water read by the pressure sensor and the known distance from the sensor to the rim of the pipe can be used to calculate the depth of the water over the rim of the pipe.

4.3 External Ultrasonic Flow Meter

A pair of externally mounted ultrasonic flow meters would be placed on the outside wall of all eight storm discharge pipes in the Screen Facility. The external ultrasonic flow meters would be non-invasive to the discharge piping, requiring no cutting or welding to install, as they are mounted using a tensioning belt fastened around the circumference of the pipe.

An external ultrasonic flow meter utilizes ultrasound to measure the velocity of a fluid via a pair of transducers on the outer pipe wall. Velocity is measured by measuring the transit time of the ultrasound to travel between the two transducers, where transit time is directly proportional to the velocity. The measured velocity is converted to a flow rate by using the known cross-sectional area of the pipe.

Figure 4-2 shows a diagram of a pair of ultrasonic transducers mounted externally on a pipe.

Figure 4-2
Externally Mounted Ultrasonic Flow Meter Transducers

4.4 Internal Ultrasonic Flow Meter

A pair of internally mounted ultrasonic transducers would be placed within all eight storm discharge pipes in the Screen Facility. The ultrasonic transducers would be invasive to the discharge piping and could require cutting of the pipe to install the transducers and ancillary equipment.

An internal ultrasonic flow meter utilizes ultrasound to measure the velocity of a fluid via a pair of transducers on the inner pipe wall. Velocity is measured by measuring the transit time of the ultrasound to travel between the two transducers, where transit time is directly proportional to the velocity. The measured velocity is converted to a flow rate by using the known cross-sectional area of the pipe.

4.5 Spool Piece / In-Line Magmeter

A spool piece magmeter would be installed into each storm discharge pipe for this alternative. This process would require cutting out a section of pipe and installing new flanges to bolt the magmeter in place of the removed pipe. Two 54-inch and six 72-inch inner diameter magmeters would be needed for this alternative. There are two possible locations for the installation of a spool piece magmeter and are identified in Sections 4.5.1 and 4.5.2.

A spool piece or in-line magmeter works to measure flow rate by utilizing Faraday's law of induction. Magmeters operate based on the principle that a voltage is induced in an electrical conductor moving through a magnetic field, where the conductor is the flowing water being measured. The magnitude of the induced voltage is proportional to the velocity of the conductor. Electrodes on each side of the pipe sense the flow-induced voltage created by magnetic coils. The measured velocity is converted to a flow rate by using the known cross-sectional area of the pipe. In the case of a spool piece or in-line magmeter the electronics are integrated into the spool piece.

4.5.1 Spool Piece Magmeter in Vertical Piping in Screen Facility

One variation of this alternative is to install the spool piece magmeter into the vertical section of each storm discharge pipe in the Screen Facility. As stated above, this would require cutting out a section of the vertical discharge pipe and installing a flange to bolt the magmeter in place.

4.5.2 Spool Piece Magmeter in Horizontal Discharge Piping

The other variation of this alternative is to install the spool piece magmeter into the horizontal run of each storm discharge pipe between the storm pumps and the Screen Facility. This would require cutting out a section of pipe and installing flanges to bolt the magmeter in place. This would also require excavation of the buried horizontal discharge piping and demolition of the concrete encasement surrounding the discharge piping.

Figure 4-3 shows an example of a spool piece magmeter.

Figure 4-3
A Spool Piece or In-Line Magmeter

4.6 Calculated Storm Pump Flow Using Ovation Data

The storm wet well basin level and pump activity monitored in the Ovation data can be used to perform a calculation that estimates the flow rate through each active pump based on pump curves and run time. This calculation does not provide the level of certainty that is desired for the Oakwood CSO RTB influent metering but is an alternative to add a backup method of calculating the flow rates through the storm pump discharge pipes. This calculation would take place within Ovation and the data would be readily available should measurements from the flow meters be unusable for any reason.

This is planned for development and testing later in the design phase.

4.7 Metering Flow Upstream of Storm Wet Wells

The influent sewer has several manholes that provide access to the flow and would be suitable for the installation of a flow meter such as an advanced Doppler meter or a transit-time meter including those offered by Nivus, Accusonic, and GWF. This alternative would require only one meter in the influent sewer to the storm wet wells, as shown in **Figure 4-4**, however an additional meter would be required if additional influent sewers are connected to Oakwood CSO RTB (such as the planned Oakwood District Intercommunity Relief Sewer (ODIRS)). Site work would be needed

to establish power, install a meter cabinet, and obtain a signal from any upstream metering location.

This alternative would provide a good measurement of the total influent flow rate but would not allow flow rate through any individual storm pump to be monitored. However, this alternative could be used in conjunction with Alternative 4.6 to allocate the influent measured flow rate to each individual storm pump.

Although this alternative does not provide the storm pump flow rates needed for chlorine feed rates, it has merit for future considerations related to the disinfection process as the system automation and machine learning process advances for the integrated CT method. The monitoring of collection system influent flow to the facility could be a valuable addition to understanding the flow coming to the facility.

This meter placement would provide unique data that would not be made redundant by the meter alternatives measuring and estimating the CSO Basin influent flow nor the calculated Storm Pump flow using Ovation data.

Figure 4-4 Potential Upstream Flow Meter Location (Background drawing source: PCS-79 Dated 11/13/09)

4.8 Alternatives Evaluation Criteria

Several criteria were developed to evaluate the expected performance and feasibility of the flow meter alternatives.

4.8.1 High Expected Accuracy

A suitable meter ideally needs to report within $\pm 2\%$ of the actual flow rate through the discharge piping, although up to $\pm 5\%$ may be acceptable. High accuracy is needed to reliably use the meter readings to automate the chemical feed system.

4.8.2 Ability to Measure Full Range of Expected Velocities

Based on flow velocity calculations through the discharge piping, the flow meters should be able to measure a minimum of 6.2 ft/s and a maximum of 9.8 ft/s. These velocities assume a minimum flow rate of 64 MGD and 120 MGD of the flow for the 54-inch and 72-inch discharge pipes, respectively, and a maximum flow rate of 98 MGD and 178 MGD for the 54-inch and 72-inch discharge pipes, respectively. These assumed flow rates are based upon preliminary future pump operating ranges.

Table 4-1 summarizes the minimum and maximum velocities through each size discharge pipe.

Table 4-1 Minimum and Maximum Velocity Through 54-Inch and 72-Inch Discharge Pipe

Parameter	54-Inch Pipe		72-Inch Pipe	
Pipe Diameter (inches)	54	54	72	72
Flow Rate (MGD)	64	98	120	178
Area (sq. ft.)	15.9	15.9	28.3	28.3
Velocity (ft/s)	6.23	9.53	6.57	9.74

4.8.3 Compatibility with Site Constraints

The site constraints consist of meter compatibility with 54-inch and 72-inch diameter pipes, level of disruption to the structural integrity of the facility necessary to install the meter, meter accessibility for maintenance, and meter resistance to submerged and corrosive environments.

4.8.4 GLWA CSO Improvements Project Guiding Principles

The GLWA CSO Improvements Project Guiding Principles provide general guidelines that direct the design process. Pertinent guidelines include:

- Do not replace equipment in kind – make it better
- Provide equipment which is accessible and easy to maintain
- Maintain operation of Oakwood facility throughout construction phase

5.0 Alternatives Analysis

The following subsections compare the metering technology alternatives to the alternative evaluation criteria. A summary of the meter alternative evaluation is presented in **Table 5-1**. Detailed information on the metering technology is presented in the subsequent sections of this memorandum.

Table 5-1 Evaluated Flow Meter Technology Summary

Meter Technology	Meets Evaluation Criteria (Yes/No)			Recommended (Yes/No)
	Accuracy	Velocity	Site Compatibility	
Insertion Magmeter	No	Yes	Yes	No
Insertion Advanced Doppler	Yes	Yes	Yes	Yes
Level Sensor	No	N/A	Yes	No
External Ultrasonic	Yes	Yes	No	No
Internal Ultrasonic	Yes	Yes	No	No
Spool Piece/In-line Magmeter	Yes	Yes	No	No

5.1 Insertion Meter

For all insertion meter alternatives discussed, the existing hot tap sleeves/port ball valves at the Oakwood CSO RTB MH yard vaults can be reused. All insertion meter technologies discussed also offer hot tap installation, meaning the meter can be removed and inserted into the pipe without interruption to pump service.

5.1.1 Insertion Magmeter

The Design Team evaluated the AquaProbe FEA100 manufactured by ABB. This insertion meter uses the design principles of a magmeter. The flow meter is compatible with pipe diameters ranging from 8 to 300 inches in diameter. The meter has a flow measurement uncertainty of $\pm 2\%$ of the flow rate and can measure velocities in a pipe up to 16 feet per second. The meter probe insertion length into the pipe for this meter is typically $\frac{1}{8}$ to $\frac{1}{2}$ of the pipe diameter. The insertion length for the 54- and 72-inch diameter pipes will be at least 6 inches and 9 inches, respectively. This level of insertion means that wastewater debris catching on the meter is likely, and the probes will be susceptible to wear. Because of the insertion length, the AquaProbe meter is not recommended.

5.1.2 Advanced Doppler Insertion Meter

The Design Team evaluated advanced Doppler insertion meters such as the CS2 Correlation Pipe Sensor manufactured by Nivus or the GWF Q-Eye advanced Pulse-Doppler. These insertion meters utilize digital pattern detection to measure flow velocity. The Nivus flow meter is compatible with the Oakwood CSO RTB storm pump discharge pipe configuration. The flow meter is expected to provide a high accuracy for the given pipe diameter, available straight run, and expected fluid velocities. These meters have a flow measurement uncertainty of less than $\pm 1\%$ of the flow rate for the velocities expected in the storm pump discharge pipe. The meter probe inserts into the open pipe area with minimal protrusion. The probe itself needs to be inserted less than 1 inch into the open pipe area, making the probe nearly flush with the pipe wall. These insertion meters have little concern of catching wastewater debris. These meters are also offered with materials available to coat the flow sensor to protect against possible corrosion from the chlorine disinfectants injected into the wastewater upstream of the meter location. The Nivus CS2 Correlation Pipe Sensor specifically is made up of a stainless-steel sensor body and a polyetheretherketone (PEEK) sensor

which offers very good chemical resistance. Additional information on these meters can be found in Appendix A and B. This meter technology is the recommended alternative.

5.2 Level Sensor

The Design Team evaluated level sensors that would be used to measure the level of the wastewater over the rim of the storm pump discharge piping in the Screen Facility. Along with the development of a suitable hydraulic formula, the level over the rim would be used to calculate the flow rate out of the discharge piping. This method is problematic as the relationship of depth over the rim to estimated flow rate may vary over the range of expected flow rates and due to other factors, such as water level in the RTB. The certainty of this method to properly measure the flow rate is unknown for the down looker level sensor and pressure sensor alternatives.

This method was deemed not viable by the Design Team because of the uncertainty of the methodology to adequately measure the level of the water over the rim of the discharge piping. As this uncertainty poses a risk to obtaining good flow rate data, the level sensors are not a viable alternative.

5.3 External Ultrasonic Flow Meter

An external ultrasonic flow meter evaluated by the Design Team was the NIC Clamp-On Sensor manufactured by Nivus. This meter operates as an ultrasonic time transit sensor. It is compatible with pipes ranging from 2 to 236 inches in diameter. The meter has a measurement uncertainty of $\pm 0.1\%$ of the measured velocity and can measure velocities in a pipe up to 32 feet per second. The flow meter transducers would be mounted on the vertical section of the discharge piping in the Screen Facility. A 0.5mm pipe wall thickness is required to mount the transducers. The transducers do not require any welding or cutting of the pipe to mount them, but instead are mounted using a tensioning belt fastened around the circumference of the pipe.

Although the transducers would be outside of the pipe, they would still be subjected to submersion as the Screen Facility fills during a storm event. As such, the transducers and associated mounting equipment need to be able to withstand the wetted and corrosive environment in the Screen Facility. The Nivus NIC Clamp-On Sensors cannot be submerged.

Additionally, the NIC Clamp-On Sensors require a non-turbulent flow profile to have accurate flow measurements. Due to the abrupt 90° bend in the discharge piping just upstream of where these external ultrasonic flow meters would be located, some turbulence in the pipe may be expected. For these reasons, the external ultrasonic flow meter is not a viable alternative.

5.4 Internal Ultrasonic Flow Meter

An internal ultrasonic flow meter evaluated by the Design Team was the Accusonic 8510+ flow meter and Model 7934 transducer. It is compatible with pipes ranging from four to 60 feet in diameter. The meter has a measurement uncertainty of $\pm 0.5\%$ of the flow rate.

For an internal ultrasonic flow meter application, the transducers sit inside the flow. Transducers would be mounted inside the vertical section of discharge piping in the Screen Facility.

Internal ultrasonic magmeters are typically used for buried pipes where externally mounted transducers are not possible. Internally mounted sensors either require cutting of the pipe to install or cabling ran inside the pipe, which may catch debris. These sensors would be difficult to access for maintenance purposes. The Design Team determined that an internal ultrasonic flow meter is not a viable alternative because of the difficulty of installation and maintenance.

5.5 Spool Piece / In-Line Magmeter

The Design Team evaluated the SITRANS FM MAG 3100 spool piece magmeter manufactured by Siemens as an alternative technology to replace the existing storm pump flow meters. This meter is compatible with pipes ranging from 0.5 to 78 inches in diameter. It has a measurement uncertainty of $\pm 0.2\%$ of the flow rate and a measurable velocity of up to 32 feet per second.

5.5.1 Spool Piece Magmeter in Vertical Piping in Screen Facility

A spool piece magmeter placed in the vertical section of discharge piping in the Screen Facility presents a few issues. There is bracing in place in the Screen Facility to provide stability to the discharge piping that would be difficult to work around and could potentially require removal to install a spool piece magmeter. Re-welding this bracing to the magmeter is of concern because of the possibility of damage to the magmeter due to the heat generated when welding. Further, there is concern that the integrity of the bracing may not be restored.

A spool piece magmeter would require a large amount of corrosive protection. The magmeter would be prone to submersion as the Screen Facility fills during a storm event. The existing vertical pipes in the Screen Facility have a corrosion-protection liner applied to the exterior. A similar protective lining would need to be applied to the spool piece magmeters and reapplied to the pipe and other affected steel surfaces following installation.

Due to the structural implications of installing a spool piece magmeter at all eight storm pump discharge pipes, the Design Team has deemed the spool piece magmeter not a viable option. The installation of this meter alternative would be too disruptive to the structure of the facility and is not compatible with the Screen Facility.

Figure 5-1 shows the storm pump vertical discharge piping the Screen Facility. The discharge piping is stabilized by the bracing seen on the left side and top of the image.

Figure 5-1
Existing Storm Pump Vertical Discharge Piping in Screen Facility

5.5.2 Spool Piece Magmeter in Horizontal Discharge Piping

Inserting a spool piece magmeter in the horizontal run of discharging piping (along where the Existing Meters are placed) was vetted as a possible alternative as well. This option was dismissed as the discharge piping is encased in concrete, making this option is cost-prohibitive, disruptive to the facility, and would reduce the integrity provided by the concrete encasement.

5.6 Calculated Storm Pump Flow Using Ovation Data

Calculating the storm pump flow rate using Ovation data and storm wet well levels at the Oakwood CSO RTB has the benefit of providing a backup flow rate estimate to the selected flow meter alternative. This alternative would be simple to implement and does not interfere with the current operations at the facility.

This alternative will require development and testing later in the design phase. Proper development and calibration of the relationship of pumped flow rate to the storm wet well level, pump curve, pump speed (when applicable), and storm pump on/off is needed to provide an accurate estimate of the storm pump flow rates and agrees with the primary method of metering. This is recommended to be implemented as a backup to the new flow meters.

5.7 Metering Flow Upstream of Storm Wet Wells

Metering the flow entering the facility as influent to the Pump Station storm wet well was determined to not be a feasible alternative for the purposes of the Oakwood CSO RTB influent flow rate metering. Metering the flow upstream of the pumps would lead to uncertainty in chemical feed dosing, as the flow rate entering the facility's storm wet wells is not necessarily equal to the flow rate pumped from the storm pumps.

However, metering flow upstream of the storm wet wells could be beneficial to the needs of the disinfection process. An upstream flow meter would provide influent flow rate data to help train an artificial intelligence / machine learning dosing model that is intended to optimize the disinfection system operation at the Oakwood CSO RTB and Pump Station.

Another advantage of adding a flow meter on the influent sewer is that it could allow confirmation that the meter is operating or developing any failures between wet weather events and corrective maintenance could be performed. If an advanced Doppler sensor, like those offered by Nivus or GWF, is installed on the bottom of the pipe, it will have flow present during dry weather as well as storm events in the existing influent sewer. The accuracy of the meter may be reduced at very low depths, but operating issues could be identified between storm events. If a multi-path acoustic meter, like those offered by Accusonic or GWF, is installed then this advantage would only be achieved if the lowest velocity sensor path can be placed below the dry weather flow depth in the sewer.

There are some disadvantages of also metering upstream of the Pump Station in addition to the meters needed on the storm pump discharge pipes. This will be an additional meter to maintain, however there may be some efficiency in that maintenance could be performed by the same team that is maintaining the flow meters on the discharge pipes. There is the potential for debris to catch on the sensor or cable and require corrective maintenance to clean the sensor, however the sensors are streamlined to minimize this occurring. Finally, the invert of the pipe at the location shown in **Figure 4-4** on the Oakwood CSO RTB site is 61.79 ft. This is below the typical wet well level operating range for the storm pumps; therefore the flow meter depth and velocity will be affected by backwater from the wet well. The advanced Doppler sensors or multi-path acoustic meters are generally capable of metering in backwater flow conditions, but the accuracy may decrease as the sensors may see rapidly increasing and decreasing depths and velocities as the pipe experiences the fill/draw cycles of the wet well.

This alternative should be explored more in depth under a separate contract, as the benefits of this alternative do not meet the needs of the individual chemical feed system installed on each storm pump.

Table 5-2 provides a comparison of the major advantages and disadvantages for the influent sewer and storm discharge piping flow meter alternatives.

Table 5-2 Flow Meter Location Alternative Comparison

Flow Meters Along the Storm Discharge Piping		Flow Meter in Influent Sewer Upstream of Wet Well	
Advantages	Disadvantages	Advantages	Disadvantages
Capable of high accuracy flow measurement in the expected flow rate range	More possible points of failure due to use of eight devices	Requires maintenance for a single device	Measured flow rate will not equal exactly the flow being pumped due to wet well and upstream in-system storage
Will measure the flow rate from each individual pump		Desire for future considerations related to the disinfection optimization process	Additional meter required with construction of ODIRS connection to the Oakwood Wet Well
Reuses existing infrastructure for flow meter installation		Available for dry-weather calibration	Flow meter depth and velocity may be affected by backwater from the wet well. Backwater conditions will occur periodically throughout each wet-weather event due to storm pump operations. Dry-weather calibration may not be applicable at peak flow rates

6.0 Life Cycle Cost Analysis

Based upon the previous alternative analysis discussed in Section 5, the Design Team has determined that a life cycle cost analysis is not necessary for this portion of the improvement project. Only the advanced Doppler insertion meter technology installed in the storm pump discharge pipes was deemed feasible for this application. All other technologies present limiting factors that eliminated them from further consideration for this task.

7.0 Summary, Recommendations and Key Decisions

The Existing Metering technology does not provide accurate and reliable flow readings at the Oakwood CSO RTB and Pump Station. Flow metering upstream of the Pump Station was evaluated but is not recommended at this time. An upstream flow meter would provide operators with the total facility influent flow rate but would not provide performance data of the individual pumps. Flow rate data for the individual pumps is helpful for monitoring the performance of the pumps over time and chlorination of the flow to the RTB.

The advanced Doppler insertion meter is the recommended replacement meter alternative for all eight of the storm pump discharge pipes. With proper installation and setup, this meter should provide accurate flow rate readings on the individual pump discharge lines which will allow accurate flow readings into the basin. This should also provide the flow rates needed for the disinfection process improvements at the facility. When the flow meters are installed, it is also recommended to monitor diagnostic parameters such as signal strength to improve maintenance efficiency, for example by identify when sensor cleaning is needed, and monitor meter performance

In addition, Ovation should be updated to include a flow rate estimate based on storm wet well levels and storm pump run time. This should serve as a secondary estimate for flow rate through the discharge piping and could be used to check/confirm the accuracy of the flow meters over time.

Future consideration for an advanced Doppler or acoustic flow meter installed in the influent sewer upstream of the storm wet well to measure the Oakwood CSO RTB influent flow rate, is also recommended. The monitoring of collection system influent flow to the facility, could be a reliable addition to understanding the flow coming to the facility and provide useful data for future advanced disinfection system analysis and programming with machine learning.

7.1 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

- GLWA agreed with the recommendation to meter Oakwood basin influent flow using insertion type advanced Doppler flow meters on the storm pump discharge pipes, if can demonstrate that reliable for the proposed meter type in wet/dry application.
- GLWA agreed with the recommendation for backup flow estimate to be calculated within Ovation

8.0 Next Steps

The following steps will be completed during the design phase of this project.

- Complete evaluation of GWF and Nivus as comparable manufacturers for the advanced Doppler insertion meter technology.
- Evaluate the feasibility of re-using the existing sealing equipment with recommended Nivus or GWF insertion meter.
- The Design Team will work with GLWA staff and consultants to develop the operational strategy for Ovation to include the backup flow rate calculations based on storm wet well levels and pump run time. This step is recommended as the primary flow metering methodology until the existing flow meters are replaced.
- Coordinate with I&C lead and GLWA to include monitoring diagnostic parameters such as signal strength and potentially other parameters related to meter diagnostics and performance in Ovation. The team will coordinate on how to store this information so it can be accessed and monitored, but only the flow rates will be included on a main operating screen.

Appendices

Appendix B – GWF Advanced Pulse-Doppler Sensor Information

Appendix A

Nivus CS2 Correlation Pipe Sensor Information

NivuFlow 750 NivuFlow 700

High accurate flow measurement for slightly polluted and dirty media in part filled and full pipes, channels and more

Our proven transmitter family systematically developed further

Flow measurement systems by NIVUS stand for innovation, reliability and highest accuracy.

NivuFlow 750/700 is a fixed transmitter for continuous flow measurement, flow control as well as for storage of measurement values recorded in slight to heavily polluted media featuring various consistencies.

It is designed for use in open channels, closed and part filled pipes (NivuFlow 700: full pipes) with various shapes and dimensions. The transmitter can handle up to 3 measurement spots and up to 9 flow sensors.

Flow measurement systems at the highest technical level

- Very high measurement accuracy
- Suitable even for very difficult applications
- Up to 3 measurement spots and up to 9 flow sensors (M9 version)
- Real-time measurement of real flow velocity profiles
- Intuitive, modern operating concept for quick and easy initial start-up
- Integrated numeric flow models
- Measurement in channels, part filled and full pipes as well as flumes
- Weatherproof version for outdoor use
- Ex approval Zone 1
- High-resolution graphic daylight display
- Extensive diagnostic functions for reliable initial start-up and quick maintenance
- Compact construction for narrow switching cabinets
- Quick wiring thanks to easily accessible connection points
- Universal, standardised interfaces for easy integration
- Online connection/data transmission and remote maintenance via Internet
- MCERTS certified

Typical Applications

WWTPs, channel networks, discharge constructions, industrial wastewater networks, measurement places for billing, intakes, drainage lines, return sludge lines, recirculation lines and many more

The right sensor for each application

The complete flow measurement system consists of the NivuFlow 750/700 transmitter and the appropriate sensors.

For flow velocity measurement starting at flow levels as low as 3 cm up to several meters in pipes, flumes and channels of various shapes and dimensions there is a wide selection of sensors available: flow velocity sensors with and without integrated flow level measurement as well as air-ultrasonic flow level sensors.

Your benefits

- Absolutely zero point stable and drift-free sensors
- Low installation expenses through perfectly matched mounting accessories
- Installation under process conditions
- Various sensor constructions guarantee the best solution for each application
- Digital signal transmission for error-free connections over long distances
- Ex approval Zone 1

Air-ultrasonic sensor
for level measurement,
installed in flume crown

Flow velocity sensors
for installation on channel bottom
or channel walls

Flow velocity sensors
for installation in pipes and in the
NIVUS Pipe Profiler

Nivu Flow 750 / 700 - Universal transmitter

The intuitive one-hand operation and the bright high-resolution colour display allow quick, easy and cost-efficient commissioning on site. Additional input devices or software are not required.

The latest integrated numeric discharge models enable more accurate, more stable and more reliable determination of flow rates even under very difficult measurement conditions.

The 3D flow profile is calculated in real time and is reproducibly and verifiably indicated on the transmitter display.

Factors influencing the calculation results such as channel shapes, discharge behaviour and wall roughness are considered during flow calculation.

In addition to the compact DIN rail version there is a weatherproof field unit available featuring appropriate connection space for outdoor installation

Technical Information NivuFlow 750/700

DIN rail enclosure for easy installation in switching cabinet

Field enclosure

Power supply	85 to 240 V AC, +10 % / -15 %, 47 to 63 Hz or 9-36 V DC
Power consumption	typical 14 VA
Enclosure	Aluminium, plastic (installation in switching cabinet), plastic (field enclosure)
Protection	IP 20 (installation in switching cabinet), IP 68 (field enclosure)
Operating temperature	-20°C to +70°C
Storage temperature	-30°C to +75°C
Max. humidity	80%, non-condensing
Display	240 x 360 pixel, 65536 colours
Operation	rotary pushbutton, 2 function keys, menus in German, English, French, Swedish and other languages
Connection	plug with cage clamp terminals
Inputs	up to 7 x 4 - 20 mA, up to 4 x RS 485 for connection of up to 9 flow velocity sensors (via multiplexer)
Outputs	up to 4 x 0/4 - 20 mA, up to 5 x relays (SPDT)
Controller	3-step controller, quick close control, adjustable valve position in case of error
Data memory	1.0 GB internal memory, readout on faceplate via USB stick
Communication	Modbus, HART

You can find the complete specifications in the instruction manual or on www.nivus.com

NivuFlow is available as unit for installation in control cabinet or with a robust field enclosure

How the NivuFlow 750/700 measures

The flow measurement principle as video under: www.nivus.com

Flow cannot be measured directly. Multiple factors are required to detect the flow Q: average flow velocity and the flow cross section which leads to the general formula:

$$Q = v_{(average)} \cdot A$$

The flow cross section A is investigated by continuously measuring the filling level considering the channel shape.

The flow velocity is detected by using the particles' velocity. Most media contain a certain load of dirt particles or gas bubbles which move in the same velocity as the liquid itself.

Level measurement (h)

Accurate flow measurements require precise and reliable level detection under all hydraulic conditions. The development of a level measurement system with multiple redundancy is a result of our many years of experience. Combining hydrostatic measurement, water-ultrasound and air-ultrasound provides solutions for all measurement tasks.

External 4- 20 mA level sensors such as "i-Series" sensors or NivuBar Plus can be connected additionally.

Flow velocity measurement (v) using cross correlation

The measurement method used for flow velocity determination is based on the principle of ultrasonic reflection. One of the most modern and most efficient measurement methods for flow velocity detection is the NIVUS cross correlation method.

Existing reflectors within the medium (particles, minerals or gas bubbles) are scanned using an ultrasonic impulse with a defined angle.

The resulting echoes are saved subsequently as images or echo patterns.

A few milliseconds later a second scan follows. The resulting echo patterns are saved as well.

By correlating/comparing the saved signals, the positions of unambiguously identifiable reflectors can be identified. The reflectors can be identified at varying positions within the images since they have moved with the medium.

Overlay of image patterns

Considering the beam angle it is possible to directly compute the particle velocity and hence the medium flow velocity from the temporal shift of the reflectors.

This allows to obtain highly accurate readings without the need to perform additional calibration measurements.

Gates			
	Position	v average	v raw
1	0.065 m	0.392 m/s	0.423 m/s
2	0.074	0.403	0.421
3	0.080	0.399	0.379
4	0.088	0.410	0.393
5	0.096	0.436	0.441
6	0.106	0.481	0.507
7	0.117	0.499	0.490
8	0.129	0.522	0.504
9	0.144	0.532	0.512
10	0.160	0.542	0.522
11	0.179	0.560	0.526
12	0.201	0.546	0.512
13	0.226	0.555	0.510
14	0.257	0.547	0.502
15	0.292	0.540	0.500
16	0.333	0.531	0.503

The NivuFlow 750/700 uses up to 9 x 16 gates for flow measurement. A flow profile can be directly indicated on the display.

Your benefits

- Highest measurement accuracy
- Stable readings
- No calibration required
- Determination and indication of flow profiles

On site from anywhere

- Integrated data logger for high data security
- Saved data can be recalled at any time
- Online operation and online setting of parameters (remote control)
- Quick and comprehensive remote diagnostics of entire measurement sites

Latest Technologies

Based on the latest hydraulic models, the NIVUS-COSP system computes a dense measurement network covering the entire flow cross section from the individual measurement spots.

NivuFlow 750/700 provides options for remote maintenance, remote diagnostics and the flexible integration into process conducting systems and telecontrol networks.

- Scientifically tested, channel-specific mathematical real-time flow models
- Calculation of flow velocity distributions in proximity to walls and horizontal velocity profiles
- Velocity integration covering the entire cross section
- Ideal to investigate average flow velocities in flumes with hydraulic disturbances

EX Separation Module iXT / Multiplexer MPX

The Ex separation module iXT is a Multiplexer used for sensor connection in Ex zone 1.

The Multiplexer Type MPX allows the electronic combination of up to 3 flow velocity sensors and 3 level sensors on site.

Technical Information

Dimensions in mm

Power supply	12 V DC, max. power consumption 9 W (typ. 7 W), supplied by transmitter
Protection	IP20
Ex approval iXT	ATEX and IECEx, ATEX: TÜV14ATEX142076, IECEx: TUN14.0014
Inputs	1 (optional 2) x analog 4-20 mA loop-powered sensor connection Ex ib Gb IIB, one of them HART compatible
Outputs	2 (optional 4) x sensor connection Ex ib Gb IIB with RS485 interface
	RS 485 to transmitter

You can find the complete specifications in the instruction manual or on www.nivus.com

Perfect solutions even under difficult conditions

Your benefits

- Accurate and reliable measurement results
- Perfectly dimensioned measurement systems
- Saves costs thanks to quick and easy installation and commissioning procedures
- Low personnel expenses through integrated systems
- One competent contact person for all components

GWF Advanced Pulse-Doppler Sensor Information

Water

GWF

Q-Eye PSC

Stationary area velocity flow meter for partially filled or pressurized pipes and open channels

Your benefits

- Best-in-class Doppler profiling technology:
Excellent long-time measurement stability, no need for costly on-site calibration
- Velocity profiling with logarithmic interpolation:
No blanking zone at bottom of channel or pipe. Highest accuracy in flow measurement for optimized process control
- Smallest area velocity sensor worldwide:
No disturbance of the flow profile, velocity measurement starts at 2 cm (< 1") water level
- Platform-independent web interface for configuration, operation and maintenance:
Easy and fast setup with multi-language graphical user interface. Parametrization with any mobile device, no software needed
- Integrated Wi-Fi access point and LAN interface, optional mobile connection:
Efficient system integration, real-time remote access anytime and anywhere
- Passive sensor, no electronics inside:
Maximum sensor robustness and lifetime, minimized total cost of ownership

Application

- Full or partially full pipes 100-2000 mm (4-80") in diameter or open channels with flow depths of 40-2000 mm (1.5-80")
- Ideal for sites with non-uniform or rapidly changing flow behavior. Suitable for applications with low and high water levels
- Continuous flow monitoring in slightly to heavily polluted media:
 - Wastewater treatment plants
 - Wastewater collection systems
 - Urban drainage
 - Industry

Features

- Compact aluminum housing, IP66 (NEMA 4)
- Smallest area velocity sensor worldwide, IP68
- Insertion sensor which does not protrude into the flow, IP68
- Pulse-Doppler Spectral Correlation technology
- Scanning of the entire velocity profile in up to 18 measuring cells
- Measurement of low velocities down to 0.04 m/s
- Bi-directional measurement over the entire flow range
- Typical accuracy: $\pm 2\%$ of reading for flow
- Integrated Wi-Fi access point
- Graphical user interface in multiple languages
- All units for display and data storage can be customized by the user
- Preselection of typical cross sections or user-definable irregular shapes
- Analog inputs for external sensors (2-wire loop-powered)
- Multiple analog and digital outputs, user programmable
- Communication: Ethernet, Modbus RTU/TCP, optional 4G/3G/2G modem
- Power supply: 100-240 V AC or 9-36 V DC
- ATEX for area velocity sensor available

Application

- Area velocity sensor to be mounted on pipe or channel bottom (up-looking) or wall (side-looking)
- Several velocity sensors in one cross section (up to 3)
- Insertion sensor for pipes only accessible from the outside
- Additional external level sensors (pressure, non-contact ultrasonic or radar)
- Well-established sensor mounting systems for diverse applications

Product description

Q-Eye PSC area velocity sensor

WebUI (Wi-Fi)

The Q-Eye PSC is equipped with an integrated web server running a WebUI. You can display and manage the WebUI using the standard web browser of your smartphone, tablet PC or notebook. There is no need for any additional software or App. Parameter setting and data visualization has never been so easy.

Data storage and transmission

Combine the Q-Eye PSC with a 4G/3G/2G cellular modem for automatic data transmission. The logged data can be sent to any host computer (FTP server) or to the GWF web-based cloud solution at a user-selectable interval (e.g. 4 times a day, once a day or once a week). Alternatively, wireless LAN and Ethernet connections are available.

Information on level, velocity, flow and signal strength can be taken at regular intervals between 1 minute and 60 minutes. In case of a flood event, the logging can be set automatically to one minute (event mode). The Q-Eye PSC is equipped with internal storage capacity (16 GB) and will store data for up to 18 months.

The Q-Eye PSC area velocity flow meter is designed for stationary flow monitoring of slightly to heavily polluted media in full or partially full pipes or open channels.

It uses advanced Pulsed-Doppler technology to directly evaluate velocity profiles, making it the best choice for sites with non-uniform or rapidly changing flow conditions. Additionally, the Q-Eye PSC measures bi-directional flow over the entire measurement range and near zero flow velocities down to 0.04 m/s. This profiling capacity eliminates the need for on-site calibration, thereby significantly reducing the cost of installation.

Q-Eye PSC insertion velocity sensor

Measuring principle

The Q-Eye PSC is a major improvement in open channel flow measurement. It's the latest entry in the GWF family of high-accuracy metering products. In contrast to the older Continuous Wave Doppler method, the Q-Eye PSC transmits acoustic pulses into the flow. These sound pulses are echoed back from particles in the medium. By time-gating the returned signals, velocity is measured in multiple cells, enabling a stepwise scanning of the entire velocity profile. Detailed velocity data in relation to the sensor location is used to calculate a highly accurate flow profile.

When compared to the Cross-Correlation method (evaluation of specific patterns in the flow), the Spectral-Correlation technology (PSC) allows for measurements in considerably more cells with a cell size of only a few millimeters. Thus the velocity profile can be measured with a much higher resolution.

By means of the PSC technology, it is possible to measure flow velocity profiles very close to the sensor as well as in greater distances. This makes the Q-Eye PSC suitable for both shallow and high water level applications.

Component description

The Q-Eye PSC system can be composed of a wall-mounted transmitter and several sensor options. The submersible area velocity sensor offers combined velocity and water level measurement for direct flow calculation with one sensor. The insertion velocity sensor can be used directly for pressurized pipes or combined with any additional level sensor for partially filled pipes.

Transmitter

Wall-mounted transmitter

The Q-Eye PSC transmitter incorporates all the required algorithms and software to ensure measurement accuracy and repeatability. The IP66 (NEMA 4X) compact housing features a 4 x 20 alphanumeric LCD display and a 4 button keypad.

All configuration data as well as measured and calculated data are stored inside a 16 GB Micro-SD card. The transmitter controls the measurements, calculates the flow rate and provides freely programmable current outputs, status alarms, frequency outputs and totalizer readings.

Sensors

Insertion velocity sensor

Low-profile area velocity sensor

The submersible area velocity sensor measures only 15 x 25 x 108 mm, making it the smallest sensor of this type currently available. Its low profile means less interference, which results in more accurate velocity measurements, especially in low-flow situations.

The insertion sensor is used when the pipe is accessible from the outside only. This sensor is for use in full pipes or partially full pipes in combination with an external level sensor (e.g. pressure or ultrasonic). These sensors can be installed into existing pipework through a 5 cm / 2" ball valve.

Mounting systems

Mounting plate, spring ring and scissors rings

Standardized accessories including mounting plates, spring and scissors rings are available. Thus, the sensors can be installed within minutes, reducing time in the manhole. The sensor is first attached to a carrier and can then be fixed onto any of the compatible mounting systems. To install the sensors in rectangular, trapezoidal or earthen channels, we recommend the sensor mounting plate. Stainless steel spring rings simplify sensor installation in cylindrical pipes. 8 standard diameters from 100 mm (4") to 600 mm (24") are available.

You can install the sensor and fix the cable to a mounting ring before entering the manhole. In this way, the time spent in the sewer is significantly reduced. The rings can be expanded with a screw mechanism against the wall of the sewer. The expanding pressure makes undesired shifting of the ring impossible.

The adjustable scissors ring is installed in large pipes from 500 mm (20") to 1450 mm (57") in diameter. It consists of a base element with a scissors mechanism and one or more pairs of extensions to fit the size of the pipe.

Technical data

Transmitter

Q-Eye PSC

Display	4 lines, 20 characters
Keyboard	4 keys
Datalogger	16 GB Micro SD card
Communication	RS-485, Modbus (RS-232 or RS-485), Wireless LAN, 4G (LTE) / 3G (HSPA+) / 2G, Ethernet 10/100 Mbps
Inputs	max. 4 x 4-20 mA, 2 x digital
Outputs	max. 4 x 4-20 mA, 4 x relay, 2 x digital
Power supply	9-36 V DC or 100-240 V AC (50/60 Hz)
Approval	IP66 (NEMA 4)
Enclosure	Aluminum
Operating temperature	-20 °C to +60 °C
Storage temperature	-20 °C to +70 °C
Dimensions	270 x 256 x 139 mm (L x W x H)

Sensor

Area velocity sensor

Sensor	1 x velocity 1 x water level
Frequency	1 MHz
Range	Velocity ± 5.3 m/s Water level 0.04 - 1.3 m expandable with external 4-20 mA level sensor
Accuracy	Velocity: ± 0.03 m/s from -1.5 m/s to +1.5 m/s ± 1 % of reading from -5.2 to -1.5 m/s and +1.5 to +5.2 m/s Level: ± 0.5 % FS (1.5 m) Flow: typically ± 2 %, depending on site conditions
Cable length	10 m incl. (max. 80 m)
Particle concentration	> 50 ppm
Material	Epoxy
Protection class	IP68 (48 h at 50 kPa, NEMA 6P)
Approval	ATEX (option)
Dimensions	108 x 25 x 15 mm (L x W x H)

Sensor

Insertion sensor

Sensor	1D velocity sensor for partially and fully filled pipes incl. 50 mm (2") ball valve
Frequency	1 MHz
Range	± 5.3 m/s (velocity)
Accuracy Velocity	± 0.03 m/s from -1.5 m/s to +1.5 m/s ± 1 % of reading from -5.2 to -1.5 m/s and +1.5 to +5.2 m/s
Cable length	10 m incl. (max. 80 m)
Material	Stainless steel 1.4301 (AISI 304)
Dimensions	Diameter: 50 mm (2")

2.9 Facility Hydraulic Models, TM-1

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Andrew Wood, Applied Science, Inc.
Keaton LeFevre, Applied Science, Inc.
John Michalski, Applied Science, Inc.*

Date: June 1, 2023

*Subject: TM-1 Facility Hydraulic Models
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

Hydraulic models were created of the Leib Combined Sewer Overflow (CSO) Screening and Disinfection Facility (SDF) and the basin component of the Oakwood CSO Retention Treatment Basin (RTB) and Pump Station to develop updated hydraulic profiles. The hydraulic profiles were provided to the Great Lakes Water Authority (GLWA) CSO Facilities Improvements (2101475) Project Design Team to assist in the design and evaluation of facility improvement projects.

Profiles were developed for existing and proposed conditions through the Leib CSO SDF and existing conditions through the Oakwood CSO RTB. The energy grade lines (EGLs) showed levels that met the acceptable surcharging criteria for the conditions that were analyzed.

1.0 Introduction and Purpose

The purpose of this memorandum is to summarize the development and calibration of the hydraulic models that were used to create hydraulic profiles through the Leib CSO SDF and the Oakwood CSO RTB and Pump Station. The hydraulic profiles were used to evaluate existing conditions in the facilities and aid in the design of proposed facility upgrades that are discussed in more detail in a separate technical memorandum. (TM).

The hydraulic models were created using the Transient Analysis Program (TAP) software. TAP is a one-dimensional program that can accurately calculate head loss through model elements by dividing the elements into small uniform cells. The head loss calculations are completed for each cell instead of each element which ends up providing more detail through the facilities. Record drawings of the Leib CSO SDF and the Oakwood RTB were used to develop model geometry. Manufacturer head loss calculations were used to calibrate the losses through the screens at both facilities. The model development and calibration are discussed in more detail in subsequent sections of this technical memorandum.

2.0 Existing Systems Description and Conditions

The focus of the modeling effort was on the Leib CSO SDF and the RTB component of the Oakwood CSO RTB and Pump Station. Details of both facilities are provided in the following sections.

2.1 Leib CSO Screening and Disinfection Facility

The Leib CSO SDF was constructed in 2002 to screen and disinfect wet weather flows in the Conant-Mt. Elliot Sewer. Dry weather flows are directed through the facility to the Toward Treatment (TT) sewer which conveys the wastewater flow to the Detroit River Interceptor (DRI). Flows that exceed the facility's dry weather capacity will pass through screens and receive treatment in a disinfection chamber before being sent through a nearly 1-mile-long effluent conduit before discharging into the Detroit River.

The facility was intended to be a full-scale pilot facility and employs two types of screening technologies.

1. Raked horizontal bar screen (originally manufactured by Copa)
2. Raked vertical bar screen (manufactured by Romag)

There are four screening channels in the facility, with a total of eight Copa screens and a total of four Romag screens. The focus of the modeling effort on this project was through the treatment stream of the Leib CSO SDF which included flow through the screens. A plan view of the facility is presented in **Figure 2-1**.

Figure 2-1
Plan View of Leib Facility

2.2 Oakwood CSO RTB and Pump Station

The Oakwood CSO RTB and Pump Station services the Oakwood Sewer District in the City of Detroit. This facility was completed in 2012 and replaced an older pump station facility servicing the same area. The Oakwood CSO RTB and Pump Station provides the pumping and CSO treatment capacity needed to meet NPDES permit requirements as well as provides the upstream customers with a higher level of service.

The Oakwood Pump Station has a firm capacity of 1,660 cfs and a total capacity of 1,950 cfs. There are a total of eight storm pumps at the Oakwood Pump Station. These pumps discharge to the RTB. Pumps 1, 2, 5 and 6 have variable frequency drive (VFD). Pumps 3, 4, 7, and 8 are constant speed pumps. Pumps 1 and 2 each have a rated capacity of 150 cfs. Pumps 3 through 8 each have a rated capacity of 275 cfs. Once the RTB is full, treated overflow discharges from the RTB to the O'Brien Drain and then runs to the Rouge River.

The stormwater pumps convey flow to the RTB. The RTB consists of two basin compartments which provide a total of 9 MG of storage. Six screens upstream of the basin compartments remove large debris from the flow stream. Excess volume is discharged through the effluent conduits to the O'Brien Drain and out to the Rouge River.

The focus of the modeling effort on this project was through the retention treatment basin. Hydraulic grade lines were developed through the facility from the stormwater pump discharge piping to the effluent channel. A plan view of the facility is presented in **Figure 2-2**.

Figure 2-2
Plan View of the Oakwood CSO Facility Screen Chamber and CSO Basins

3.0 System Evaluation

The energy grade line through the Leib CSO SDF and the Oakwood RTB were calculated in TAP. TAP is a computational hydraulics program developed by Applied Science, Inc. (ASI) that can simulate steady-state, gradual time-varying, and rapidly-varying flow conditions for both open and closed conduit systems. TAP was selected for this modeling effort due to its ability to accurately model head losses in a system or facility. TAP divides conduits into uniformly-spaced small cells to determine the energy grade line and hydraulic grade line through the element. For each cell and each timestep, the fully dynamic equations are solved, and cell averaged quantities of depth, area, velocity, and flow rates are provided.

TAP models were created for the Leib CSO SDF and Oakwood RTB. The TAP models were run for steady-state conditions for a series of design flow rates and operational conditions.

3.1 Model Development

The TAP models were developed using a combination of as-built drawings provided by GLWA and head loss curves provided by the screen manufacturers. The TAP models contain the major components in the facilities which include the influent and effluent channels, weirs, gates and screens. The major facility components that were modeled in TAP are presented on schematics shown in **Figures 3-1** and **3-2**.

Figure 3-1
 Leib CSO SDF TAP Schematic

Figure 3-2
Oakwood CSO RTB TAP Schematic

3.1.1 Model Head loss

As-built drawings were reviewed and used to develop the TAP models. The minor loss coefficients used in the TAP model were based on the facility geometry. Entrance and exit head loss coefficients for the influent channels, gates, weirs, and effluent channels were taken from established literature. The head loss coefficients typically ranged as given in **Table 3-1**.

Table 3-1 Hydraulic Structure Head Loss Coefficients

Head loss Component	Minimum Coefficient (K)	Maximum Coefficient (K)
Abrupt Contractions	0.10	0.50
Abrupt Expansions	0.20	1.00
Gradual Expansions	0.00	0.02
Gradual Contractions	0.00	0.04
Entrance	0.10	0.50
Exit	0.30	1.00

The screen losses for the Leib CSO SDF and the Oakwood RTB were calibrated to match the head loss information provided by the screen manufacturer. Each screen manufacturer provided head loss information for a series of flow rate and downstream boundary conditions. This information was used to develop head loss curves for the screens since the losses vary based on both flow rate and downstream level.

TAP mini-models were created to calibrate the screen head losses. The entrance and exit losses for the screen elements were calibrated to produce head loss that matched the developed head loss curves. This was an iterative process that required the element entrance and exit losses to be adjusted for a range of flow rates provided on the head loss curves. The screen model representation from the calibrated mini models was then incorporated into the overall facility TAP models.

The modeling effort assumed some level of screen blinding. The screen manufacturers provided recommendations for the percentage blinding that should be assumed during peak flow conditions. The screen design team adopted these blinding percentages for the hydraulic analyses. The percentage blinding varies by each screen manufacturer and screen technology and is summarized below.

- Leib CSO SDF Copa Screens: 50% blinding
- Leib CSO SDF Romag Screens: 25% blinding
- Leib CSO SDF Duperon Multi-Rake Screens (Proposed Pilot): 30% blinding
- Oakwood RTB Perforated Plate Screens: 20% blinding

Calibration head loss curves can be found in Appendix B of this memorandum.

3.1.2 Model Flow Rates

Steady-state flow rates used in this analysis were taken from an existing SWMM5 model of the regional collection system. The Regional Wastewater Collection System (RWCS) SWMM5 model was developed under the Wastewater Master Plan (WWMP) and has been used for collection system project planning and decision-making purposes. The RWCS model includes representation of the Leib Facility and the Oakwood CSO RTB and Pump Station and was used to generate the steady-state flow rates used in the TAP modeling effort.

Future collection system projects are proposed upstream of both the Leib CSO SDF and the Oakwood CSO RTB and Pump Station that would increase the wet weather flows to the facilities. A connection from the Meldrum Sewer to the Leib CSO SDF is being considered that would send all dry weather and wet weather flows from the Meldrum Sewer to the Leib CSO SDF. The Oakwood District Intercommunity Relief Sewer (ODIRS) Project has been designed to send excess wet weather flow from the Northwest Interceptor (NWI) to the Oakwood CSO RTB and Pump Station. This project is designed to send wet weather flow to the Oakwood Pump Station to control

surcharging along the NWI. The RWCS design event model assumed both projects were built and are in-service.

The RWCS model was run for the 6-month, 24-hour design storm event and the 10-year, 24-hour design storm event for this analysis. The peak flow rates that were generated for these events were selected as the steady-state flow rates. A summary of the design event analysis can be found in Appendix A of this memorandum. The steady-state flow rates used in this analysis are presented in **Table 3-2**.

Table 3-2 Steady-State Flow Rates

Location	Design Event	Collection System Conditions	Steady-State Flow Rate (cfs)
Leib CSO SDF	6-month, 24-hour	Future (Meldrum Sewer Connection)	380
	10-year, 24-hour	Future (Meldrum Sewer Connection)	950
Oakwood RTB	6-month, 24-hour	Future (ODIRS)	531
	10-year, 24-hour	Future (ODIRS)	1231

3.1.3 Model Boundary Conditions

The TAP models of the Leib CSO SDF and the Oakwood RTB used fixed elevations as downstream boundary conditions. These elevations were taken from the RWCS model and are relative to the timing of the selected peak flow rate. For both models the downstream boundary elevation was the predicted level in the junction downstream of the effluent weir. The downstream boundary elevations are presented in **Table 3-3**.

Table 3-3 Downstream Boundary Elevation

Location	Design Event	Effluent Weir Elevation (ft – Detroit Datum)	Downstream Boundary Elevation (ft – Detroit Datum)
Leib CSO SDF	6-month, 24-hour	105.00	95.77
	10-year, 24-hour	105.00	103.66
Oakwood RTB	6-month, 24-hour	114.00	106.52
	10-year, 24-hour	114.00	106.52

4.0 Description of Alternatives

The Leib CSO SDF and Oakwood RTB were modeled under existing conditions. Additional modeling was completed at the Leib CSO SDF to evaluate alternative screening concepts. The modeled alternatives are described in more detail in the following sections.

4.1 Existing Conditions

The existing condition model setup for both facilities was based on a review of as-built drawings and Operations and Maintenance (O&M) manuals. Direction on operational assumptions for the modeling effort was provided by the screening and disinfection design team members.

The following assumptions were made for the existing conditions scenarios at the Leib CSO SDF.

- The Screening Outlet Gates were assumed to be in a fully OPEN position.
- The Toward Treatment gate was assumed to be partially open. The gate was opened enough to allow 10% of the total influent flow rate to be conveyed to the Toward Treatment Sewer.

The number of Screening Inlet Channels in-service varied among the existing conditions scenarios. Most of the existing condition scenarios assumed all Screening Inlet Channels were in-service to align with the original facility design assumptions. However, one existing conditions scenario was developed to evaluate the facility's firm capacity. This scenario assumed the Romag screens in the western-most Screening Inlet Channel were out-of-service.

The Oakwood RTB was analyzed for two operating scenarios under existing conditions. All scenarios assumed that one of the six perforated plate screens were out-of-service. The two scenarios summarized were:

- Five screens and both basin compartments in-service
- Five screens and one basin compartment in-service

4.2 Proposed Conditions

Proposed conditions scenarios were evaluated at the Leib CSO SDF to assess screening and operational alternatives. The following proposed condition scenarios were evaluated at the Leib CSO SDF.

- Screening Pilot Scenario – Replacement of one Copa/horizontal screen with a Duperon/multi-rake screen in the 4th (eastern-most) Screening Inlet Channel. A plan view of the proposed pilot is presented in **Figure 4-1**. The following assumptions were made for the pilot scenarios at the Leib CSO SDF.
 - This alternative was evaluated for the total facility capacity and the firm capacity of the facility. The firm capacity assumed the Romag screens in the western-most Screening Inlet Channel were out-of-service.
 - The Screening Outlet Gates were assumed to be in a fully OPEN position.

- The Toward Treatment gate was assumed to be partially open. The gate was opened enough to allow 10% of the total influent flow rate to be conveyed to the Toward Treatment Sewer.

Figure 4-1
Multi-Rake Pilot Screening Alternative

- All Romag Screening Alternative – Replacement of both Copa/horizontal screens with Romag/vertical bar screens in the 2nd and 4th Screening Inlet Channels. This concept is presented in **Figure 4-2**. This proposed scenario was modeled for one operational scenarios.
 - The Romag screens in the western-most Screening Inlet Channel are out-of-service.
 - The Screening Outlet Gates were assumed to be in a fully OPEN position.
 - The Toward Treatment gate was assumed to be partially open. The gate was opened enough to allow 10% of the total influent flow rate to be conveyed to the Toward Treatment Sewer.

Figure 4-2
Proposed All Romag Screening Alternative

Additional screening alternatives may be evaluated throughout the design phase as other screening technologies are vetted.

There were no proposed conditions scenarios evaluated for the Oakwood RTB for this hydraulic analysis. A CFD modeling effort has been completed to evaluate proposed mixing alternatives in the basin compartments for the process team. The CFD modeling effort is covered in a separate technical memorandum.

4.3 Acceptable Surcharging

Acceptable surcharging levels were established under the original design at both facilities. The performance of the concepts evaluated in this phase of the project is based on a comparison of modeled existing EGLs and proposed EGLs. The upstream HGLs were checked against acceptable surcharge levels to identify or prevent potential operational or upstream collection system issues.

4.3.1 Leib CSO SDF

For the purposes of conceptual screen design and overall hydraulic acceptability, the existing conditions steady-state EGL at the upstream end of the facility was determined to be the acceptable surcharge elevation. Based on the modeling effort outlined in this memorandum, that elevation was determined to be 111.59-ft assuming all screen inlet channels were in-service. The upstream EGL increased to 112.31-ft when one Romag screen inlet channel was taken out-of-service to represent the firm capacity of the facility.

Proposed conditions grade lines were compared to the existing conditions grade lines at the upstream end of the facility. Elevations that were less than or equal to existing conditions were determined to be acceptable.

4.3.2 Oakwood RTB

The acceptable surcharge elevation for the Oakwood RTB is 120.00-feet (Detroit Datum) or 599.25-feet (NAVD88 datum). This elevation corresponds to the storm pump discharge standpipe elevation which is shown in **Figure 4-3**. Elevations below 120.00-feet allow for free discharge conditions at the standpipe and will not impact the performance of the storm pumps.

Figure 4-3
Oakwood Storm Pump Discharge Standpipe

5.0 Alternatives Analysis

The Leib CSO SDF and Oakwood RTB TAP models were run for the 6-month, 24-hour and 10-year, 24-hour design event peak flow rates. Each model was run until steady-state conditions were reached.

The hydraulic grade line at each model node was tabulated to create the hydraulic profiles through the facilities. The profiles can be found in Appendix C of this document. The hydraulic profiles were provided to the various team disciplines for use in the evaluation of existing conditions and proposed facility modifications.

The model results are also tabulated below for the Leib CSO SDF and the Oakwood RTB in **Tables 5-1** and **5-2**, respectively.

Table 5-1 Steady-State Model Results at the Leib CSO SDF

Scenario	Description	Flow Rate (CFS)	Steady-State Energy Grade Lines (feet- Detroit Datum)				
			Upstream End of Facility	Upstream of Screens	Downstream of Screens	Over Effluent Weir	Downstream Effluent Channel
1	Existing Conditions	380	110.61	110.57	110.48	106.27	100.99
2	Existing Conditions	950	111.59	111.40	111.10	107.35	104.18
3	Existing Conditions, One Screening Inlet Channel Out-of-Service	950	112.31	111.87	110.51	107.35	104.18
4	Proposed Multi-Rake Pilot	950	111.60	111.39	110.97	107.35	104.18
5	Proposed Multi-Rake Pilot, One Screening Inlet Channel Out-of-Service	950	112.29	111.92	111.41	107.35	104.18
6	Proposed All Romag Concept, One Screening Inlet Channel Out-of-Service	950	111.81	111.52	111.16	107.35	104.18

Table 5-2 Steady-State Model Results at the Oakwood RTB

Scenario	Condition	Flow Rate (CFS)	Steady-State Energy Grade Lines (feet- Detroit Datum)				
			Upstream of Screens	Downstream of Screens	Over Influent Channel	Over Effluent Weir	Downstream Effluent Channel
1	Existing Conditions, One CSO Basin In-Service	531	114.82	114.53	114.51	114.49	110.70
2	Existing Conditions, One CSO Basin In-Service	1231	116.39	115.05	114.96	114.85	110.70
3	Existing Conditions, Two CSO Basins In-Service	1231	116.01	114.59	114.57	114.54	110.70

6.0 Life Cycle Cost Analysis

Not used.

7.0 Summary, Recommendations and Key Decisions

Hydraulic profiles were prepared for existing and proposed conditions through the Leib CSO SDF and existing conditions through the Oakwood RTB. The modeling effort showed levels that met the acceptable surcharging criteria for the conditions that were analyzed. Profiles can be found in Appendix C of this technical memorandum.

7.1 Key Decisions

Key decisions made during the course of review and presentation of this Technical Memorandum are as follows:

- As addressed in the design event memo in Appendix A, GLWA and EGLE agreed that the basis of design flow rates will be based on the peak 6-month, 24-hour and 10-year, 24-hour flow rates from the RWCS model.

8.0 Next Steps

The hydraulic profiles have been circulated to the GLWA CSO Facilities Improvements (2101475) team discipline leads to assist in the evaluation of existing equipment and any proposed modifications at the Leib CSO SDF and the Oakwood RTB.

At the time of the publication of this memorandum, the Romag alternative has been found to be hydraulically acceptable and is the preferred alternative for future modifications at the Leib CSO SDF. The hydraulic analysis for both the Leib CSO SDF and the Oakwood RTB will be revisited at major project milestones throughout the design phase to confirm that any proposed modifications will be hydraulically acceptable.

Project: GLWA CSO Facilities Improvements (2101475)

Subject: Design Storm Event and Facility Flow Rate Summary

Date: February 14, 2023

Introduction

The purpose of this memorandum is to document the selected design storm events and peak flow rates that will be used in the evaluation of the existing GLWA CSO facilities under the GLWA CSO Facilities Improvements (2101475) Project. Hydrographs through these facilities were generated using the Regional Wastewater Collection System (RWCS) SWMM model and will be used by the various team disciplines to evaluate the performance of existing equipment and any proposed modifications at the GLWA facilities.

This memorandum will summarize the peak flow rate at each facility for the selected design events and compare them to the facility design flow rates. The goal of this write-up is to get consensus from the discipline leads and the client on the direction of the project as it pertains to design criteria.

ASI intends for this to be a living document through the development of the BOD, and additional flow conditions will be simulated or analyzed by ASI, as requested, as the BOD progresses. It is understood that the CDM Smith process design team is evaluating what flows are applicable for each of the following design elements:

1. Optimization of the Chlorination Process
2. Screen Design
3. Distinguishing Between Treatment Capacity and Hydraulic Conveyance Capacity
4. Dry Weather Emergency at WRRF that prompts the Emergency Use of CSO Facilities
5. Wet Weather Worst Case – Extreme Storm Event

RWCS Model Background

The RWCS model was developed under the Wastewater Master Plan (WWMP) Project for planning and decision-making purposes. The RWCS model provides a detailed representation of the wastewater collection system as it is today and supersedes earlier collection system models including the GDRSS model which was used in the design of the CSO facilities. The RWCS model contains a detailed representation of all major GLWA assets including the four CSO Facilities that are the focus of this project: Baby Creek CSO Screening and Disinfection Facility (SDF), Conner Creek CSO Retention Treatment Basin (RTB), Leib CSO SDF and Oakwood CSO RTB and Pump Station.

The RWCS model was used for this project to provide design flow rates and hydraulic gradelines (HGLs) at the four CSO facilities. Three design events selected for this analysis are the 6-month, 24-hour, 10-year, 1-hour and 10-year, 24-hour storm events. An aerial reduction factor (ARF) was applied to the NOAA Atlas 14 rainfall totals for the two 24-hour duration storm events. The modeled rainfall totals are as follows:

- 6-month, 24-hour event: 1.10 inches (1.15 inches total with 0.96 ARF)
- 10-year, 1-hour event: 1.71 inches
- 10-year, 24-hour event: 3.18 inches (3.31 inches total with 0.96 ARF)

The 6-month, 24-hour design storm event was selected to represent the collection system response for an average wet weather event. Events smaller than the 6-month storm event had the likelihood of not producing a wet weather response at some of the CSO facilities included in this project.

The 10-year, 1-hour and 10-year, 24-hour design storm events were selected for this project because they were used in the original design of the CSO facilities with GDRSS model. The 10-year, 1-hour storm event was used to generate the design flow rates for the Baby Creek CSO SDF, Leib CSO SDF and Oakwood CSO RTB and Pump Station. The Conner Creek CSO RTB was designed around peak flow rates generated by the 10-year, 24-hour design storm event.

RWCS Model Results

The RWCS model was run for the design storm events for current and future conditions. Model predicted influent peak flow rates to each facility are summarized below in Table 1 for current conditions at all four facilities and future conditions at Leib and Oakwood based on present planning. Current conditions represents the wastewater collection system as it is today. Future conditions assumes the Meldrum connection to the Leib CSO SDF and the Oakwood District Intercommunity Relief Sewer (ODIRS) connection to the Oakwood CSO RTB and Pump Station have been constructed and are in-service. The original facility design flow rates are also included in Table 1 for comparison purposes.

The predicted peak flow rates presented in Table 1 are based on 5-minute model output. The reporting time step of 5-minutes was selected under the Wastewater Master Plan Project to match meter time stamp data. The modeling effort for this project retained these parameters.

Table 1 – Flow Rate Comparison

Facility	Facility Design Flow Rate (cfs)	Collection System Conditions (Current or Future)	Predicted 5-minute Peak Flow Rate (cfs)		
			6-month, 24-hour Design Event	10-year, 1-hour Design Event	10-year, 24-hour Design Event
Baby Creek CSO SDF ¹	5,100	Current	1,123	3,606	3,855
Conner Creek CSO RTB ²	13,252 (Treatment Capacity) 13,963 (Hydraulic Capacity)	Current	3,709	8,719	9,910
Leib CSO SDF ³	1,550 (Peak Design Flow) 2,000 (Hydraulic Capacity)	Current	118	394	520
		Future	380	510	950
Oakwood CSO RTB and PS ⁴	1,660 (Firm Capacity)	Current	135	712	765
		Future	531	1,176	1,231

Notes:

- 1) The Baby Creek CSO SDF was designed to a 10-year, 1-hour storm event with a river elevation of 92.0-feet (Detroit Datum).
- 2) The Conner Creek CSO RTB was designed to a 10-year, 24-hour design storm event with a 25-year flood level on the Detroit River (97.5-feet Detroit Datum). Treatment capacity was designed using a 10-year, 1-hour design event.
- 3) The Leib CSO SDF was designed to a 10-year, 1-hour storm event.
- 4) The Oakwood CSO RTB and Pump Station was designed to a 10-year, 1-hour storm event.

Conclusions

The RWCS model flow rates for the 6-month, 24-hour and 10-year, 24-hour design storm events presented in Table 1 will be used in this analysis. The predicted flow rates from the RWCS model are significantly lower than the design flow rates from the GDRSS model at all four CSO facilities, however the RWCS model provides a more accurate representation of the flow conveyed in the collection system to the facilities as it is today. The individual designers are to confirm the ultimate design condition for the work being proposed and use those rates for complete assessment of the performance over the range of conditions potentially experienced over the lifespan of the work.

Note on Calibration:

DS Depth obtained by sending design flow rate through Oakwood Facility model. Use flow and DS Depth to calculate head loss / US Depth in this spreadsheet. In Isolated Screen model, set flow rate and DS Depth. Tweak screen entrance loss to achieve calculated head loss. Plug calibrated entrance loss into Oakwood Facility model to obtain full hydraulic grade line through facility.

2.10 Permitting and Regulatory Requirements, TM-28

Technical Memorandum

*To: Chris Nastally, GLWA
Scott Worth, PMA*

*From: Dustin Ford, CDM Smith
Ali Khraizat, CDM Smith*

Date: June 1, 2023

*Subject: TM-28 Permitting and Regulatory Requirements
Contract No. 2101475 - CSO Facilities Improvements Project*

Executive Summary

As a part of the scope of work, the Design Team has been assigned the task of identifying and obtaining necessary permits and regulatory requirements associated with the design and construction modifications to meet the project needs. Here within is a list of the identified permitting and regulatory requirements. The Design Team will continue to evaluate these requirements and monitor their progress to help limit the impact they will have on the overall project schedule.

1.0 Introduction and Purpose

The purpose of this technical memorandum (TM) is to assist the Design Team in meeting the regulatory compliance requirements associated with the design and construction of the Oakwood and Leib Combined Sewer Overflow (CSO) Improvements. Under contract no. 2101475 the Great Lakes Water Authority (GLWA) intends to improve the Oakwood Combined Sewer Overflow Retention Treatment Basin (RTB) and Pump Station facility and the Leib CSO Screening and Disinfection Facility (SDF). These improvements are intended to improve facility reliability, flexibility, operation, maintenance and safety to support planned increases in utilization in the Oakwood CSO RTB and Leib SDF facilities. These planned increases will follow other projects planned under the Great Lakes Water Authority (GLWA) Wastewater Master Plan; these projects will divert flow from the Northwest Interceptor to the Oakwood CSO RTB, and from the Meldrum Sewer to the Leib SDF.

This TM will also assist the Design Team in identifying necessary approvals that may be incidental to the Michigan Department of Environmental, Great Lakes, and Energy (EGLE) approval process under Part 31 and Part 41 of Public Act 451 of 1994, as amended and are in the jurisdiction of agencies other than EGLE. These requirements may include approvals from various Departments in the City of Detroit, Wayne County, and EGLE.

2.0 NPDES Permit

2.1 Present Authorization to Discharge

GLWA operates the Water Resource Recovery Facility (WRRF) in accordance with effluent limitations, monitoring requirements and other conditions set forth by National Pollutant Discharge Elimination System (NPDES) Permit# MI0022802 issued on July 18, 2019. The NPDES Permit# MI0022802 authorizes discharge from the combined sewer overflow facilities to specific receiving waters including the Detroit River, the Rouge River, Conner Creek, Fox Creek, and O'Brien Drain.

Part I Section A.6 specifically identifies the outfall location, receiving stream, and conditions of authorization for the combined sewer overflow retention treatment basin located within the City of Detroit. The discharge point from the existing Oakwood CSO RTB is identified as Outfall 108 in the Permit.

Part I Section A.7 specifically identifies the outfall location, receiving stream, and conditions of authorization for the combined sewer overflow screening and disinfection facilities located within the collection system. The discharge point from the existing Leib CSO SDF is identified as Outfall 105 in the Permit.

No modification to the NPDES permit will be made as part of this project. The facility will continue to discharge to the receiving stream under the effluent limits and discharge conditions described in the present Permit. Conditions for discharge from these outfalls are outlined in the permit document and are summarized in the following section.

2.2 Facility Effluent Limits and Monitoring Requirements for Outfall 108

The following sections describe the expected effluent limits and monitoring requirements for Outfall 108 at the Oakwood CSO and RTB facility.

2.2.1 Effluent Limits

The authorized Effluent Limits for Oakwood CSO RTB - Outfall 108 are presented in **Table 2-1**.

Table 2-1 Effluent Discharge Limits for Oakwood CSO RTB

Influent Characteristics	Maximum Limits for Quantity or Loading		Maximum Limits for Quality or Concentration			Monitoring Sample	
	Monthly	Daily	Monthly	Daily	Event	Monitoring Frequency	Sample Type
Flow	(report)	(report)	---	---	---	Daily	Report Total Daily Flow
Effluent Characteristics							
Flow	(report)	(report)	---	---	---	Daily	Report Total Daily Flow
CBOD₅	---	---	(report)	(report)	---	Event	Composite
TSS	---	---	(report)	(report)	---	Event	Composite
Ammonia Nitrogen (as N)	---	---	(report)	(report)	---	Event	Composite
Total Phosphorus (as P)	---	---	(report)	(report)	---	Event	Composite
Fecal Coliform Bacteria (May 1 – October 31)	---	---	---	---	400 cfs / 100 ml	Event	Grab
Fecal Coliform Bacteria (November 1 – April 30)	---	---	---	---	400 cfs / 100 ml	Event	Grab

Event Minimum				Event Maximum			
pH	---	---	(report)	---	(report)	Event	Grab
Dissolved Oxygen	---	---	(report)	---	(report)	Event	Grab

The discharge is limited as specified in the following section:

2.2.2 Retention Basin Monitoring and Reporting

EGLE requires GLWA to monitor retention basin performance and report the monitoring to the District Supervisor of the Southeast Michigan District of the Water Resources Division. Sampling and monitoring requirements are as follows:

- Total daily influent flow must be measured and reported. No influent sampling is required.
- Effluent flow must be measured and reported for each event.

- Effluent sampling for CBOD5, TSS, Ammonia Nitrogen (as N) and Total Phosphorus is required to be by effluent flow-weighted composite sampling over the entire event. For events that occur over multiple days, the composite pollutant concentrations for the event are required to be reported on the day that the event ends.
- For Fecal Coliform Bacteria, grab samples are required to be collected every 2 hours for the first 6 hours of the event, and every 4 hours thereafter until discharge ceases. The “event maximum” is required to be reported as the geometric mean of all samples taken during an event, provided that three or more samples are collected. The goal of the effluent sampling program is to collect at least three samples during each discharge event. Samples shall be collected at shorter intervals at the onset of the event, if the permittee estimates that the event duration may be less than 6 hours.
- For Total Residual Chlorine, grab samples are required to be collected every two hours for the first 6 hours of the event, and every 4 hours thereafter until discharge ceases. The goal of the effluent sampling program is to collect at least three samples during each discharge event. Samples shall be collected at shorter intervals at the onset of the event, if the permittee estimates that the event duration may be less than 6 hours. The average of all sample taken during the event is to be reported as the “event average.” The maximum individual sample collected in the event is to be reported as the “event maximum”
- For effluent pH, the lowest value of any individual sample must be reported as the minimum. The highest value of any individual sample must be reported as the maximum. Individual values taken for each sample must be reported on the daily Discharge Monitoring Report (DMR).
- For dissolved oxygen, the lowest concentration of any individual sample must be reported as the minimum. Individual values taken for each sample must be reported on the daily DMR.

2.2.3 Retention/Treatment Basin Dewatering

The RTB is required to be promptly dewatered as soon as possible following the need to divert flow to the basin and must be maintained in readiness for use. The discharge of sludge or residual accumulations from the basin to the surface waters is prohibited. This sludge shall be promptly removed and disposed in accordance with procedures approved by the EGLE.

The CSO basin may be dewatered under the condition that up to 930 MGD (including recycle) is being processed with secondary treatment at the WRRF and no primary flow is being discharged.

2.2.4 Narrative Standard

The receiving water may contain no unnatural turbidity, color, oil films, floating solids, foams, settleable solids, suspended solids, or deposits as a result of this discharge in quantities which are or may become injurious to any designated use.

2.2.5 Operations and Maintenance Plan

Discharges may only occur in response to rainfall (or snowmelt) events and cease soon thereafter. Rehabilitation and maintenance needs must be addressed to ensure adequate sewer capacity and functionality. This is to be accomplished through the ongoing implementation of the Operation and Maintenance plan.

The following sections describe the expected effluent limits and monitoring requirements for Outfall 108 at the Oakwood CSO and RTB facility.

2.3 Facility Effluent Limits and Monitoring Requirements for Outfall 105

The following sections describe the expected effluent limits and monitoring requirements for Outfall 105 at the Leib CSO SDF.

2.3.1 Effluent Limits

The authorized Effluent Limits for the Leib CSO SDF - Outfall 105 are presented in **Table 2-2**.

Table 2-2 Effluent Discharge Limits for Leib SDF

Effluent Characteristics	Maximum Limits for Quantity or Loading		Maximum Limits for Quality or Concentration			Monitoring Sample	
	Monthly	Daily	Monthly	Daily	Event	Monitoring Frequency	Sample Type
Flow	(report)	(report)	---	---	---	Daily	Report Total Daily Flow
CBOD ₅	---	---	(report)	(report)	---	Event	Composite

			Event Minimum		Event Maximum		
pH	---	---	(report)	---	(report)	Event	Grab
Dissolved Oxygen	---	---	(report)	---	(report)	Event	Grab

The discharge is limited as specified in the following section:

2.3.2 Monitoring and Reporting

EGLE requires GLWA to monitor facility performance and report the monitoring to the District Supervisor of the Southeast Michigan District of the Water Resources Division. Sampling and monitoring requirements are as follows:

- Effluent flow must be measured and reported for each event.
- Effluent sampling for CBOD₅, TSS, Ammonia Nitrogen (as N) and Total Phosphorus is required to be by effluent flow-weighted composite sampling over the entire event. For events that occur over multiple days, the composite pollutant concentrations for the event are required to be reported on the day that the event ends.

- For Fecal Coliform Bacteria, grab samples are required to be collected every 2 hours for the first 6 hours of the event, and every 4 hours thereafter until discharge ceases. The “event maximum” is required to be reported as the geometric mean of all samples taken during an event, provided that three or more samples are collected. The goal of the effluent sampling program is to collect at least three samples during each discharge event. Samples shall be collected at shorter intervals at the onset of the event, if the permittee estimates that the event duration may be less than 6 hours.
- For Total Residual Chlorine, grab samples are required to be collected every 2 hours for the first 6 hours of the event, and every 4 hours thereafter until discharge ceases. The goal of the effluent sampling program is to collect at least three samples during each discharge event. Samples shall be collected at shorter intervals at the onset of the event, if the permittee estimates that the event duration may be less than 6 hours. The average of all sample taken during the event is to be reported as the “event average.” The maximum individual sample collected in the event is to be reported as the “event maximum”
- For effluent pH, the lowest value of any individual sample must be reported as the minimum. The highest value of any individual sample must be reported as the maximum. Individual values taken for each sample must be reported on the daily DMR.
- For dissolved oxygen, the lowest concentration of any individual sample must be reported as the minimum. Individual values taken for each sample must be reported on the daily DMR.

2.3.3 Narrative Standard

The receiving water may contain no unnatural turbidity, color, oil films, floating solids, foams, settleable solids, suspended solids, or deposits as a result of this discharge in quantities which are or may become injurious to any designated use.

2.3.4 Sampling Locations

Sampling locations for the pollutants listed in **Table 2-2** must be representative of the effluent and consistent with the locations approved by the department.

2.3.5 Operations and Maintenance Plan

Discharges may only occur in response to rainfall (or snowmelt) events and cease soon thereafter. Rehabilitation and maintenance needs must be addressed to ensure adequate sewer capacity and functionality. This is to be accomplished through the ongoing implementation of the Operation and Maintenance plan.

2.3.6 Treatment Facility Dewatering

The facility is required to be promptly dewatered as soon as possible following the need to divert flow to the facility and must be maintained in readiness for use. The discharge of sludge or residual accumulations from the basin to the surface waters is prohibited. The facility may be dewatered

under the condition that up to 930 MGD (including recycle) is being processed with secondary treatment at the WRRF and no primary flow is being discharged.

2.3.7 Quarterly Monitoring

Quarterly samples must be taken during the months of January, April, July and October. If the facility does not discharge during these months, the facility must be sampled during the next discharge that occurs during the period in question. If the facility does not discharge during the period in question, a sample is not required for that period.

3.0 Other EGLE Permits

3.1 Wastewater Collection and Treatment Facilities Construction Permit

The Water Resources Division within EGLE has responsibility for processing Wastewater Construction Permit Applications under the authority of Part 41, Sewerage Systems, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended. The purpose of this permit is to ensure that plans and specifications for wastewater facilities are complete with regard to the minimum requirements and that the proposed construction is acceptable with regard to accepted design standards for wastewater facilities to protect the public health and the environment.

A Part 41 permit for facility construction is required for any modification of the Oakwood and Leib facilities. The permit application must be completed via the EGLE MiEnviro System. The permit application form and project documents must be submitted via the MiEnviro System. Payment of fees may be made via the MiEnviro system or check made payable to the State of Michigan. Checks may be delivered by mail or in person at the following addresses:

Mail Delivery

EGLE

Cashier's Office

WB-IC

P.O. Box 30657

Lansing, Michigan 48909-8157

Office Delivery (e.g., UPS, Fed Ex, by hand)

State Transportation Building

Accounting Services Center - Cashier's Office

425 West Ottawa Street

Lansing, Mi 48933

3.2 Soil Erosion and Sedimentation Control Permit

Part 91, Soil Erosion and Sedimentation Control (SESC), of the Natural Resources and Environmental Protection Act (NREPA) (Part 91) provides for the control of soil erosion and protects adjacent properties and the waters of the state from sedimentation. A permit is generally required for any earth change activity which disturbs one or more acres of land or which is within

500 feet of a lake or stream. A permit will be required at one or both sites if site improvements work at the site meets those conditions.

Part 91 is administered and enforced by various state, county, and local governmental agencies. In this project, Wayne County is the delegated authority to regulate the work. Refer to the following section on permits required by Wayne County for information on applying for the Wayne County SESC permit.

3.3 Great Lakes Bottomlands Permit

The Water Resources Division (WRD) within EGLE, is responsible for issuing Great Lakes bottomlands permits under the authority of Part 325, Great Lakes Submerged Lands (formerly Public Act 247 of 1955, as amended), of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA). The purpose of this permit is to protect the waters of the Great Lakes and the Great Lakes bottomlands (the land lying below the ordinary high-water mark (OHWM)). This permit may be required for a project that includes outfall construction, construction in the floodplain, wetland impacts and drain crossings.

The present scope of contract includes only work within the existing project sites. Therefore, the only permits that may be required are a Flood Plain Permit, if any of the proposed construction is within the flood plain, and a Wetlands Permit, if any of the proposed construction impacts existing regulated wetlands. Based on the Flood Insurance Maps included in Appendix A, the project sites at both the Oakwood CSO RTB facility and the Leib SDF do not appear to lie within the 100-year flood plain. At this time there is no information about the presence of any regulated wetlands on the proposed site or on the proposed route for the connection to the existing discharge conduit.

3.4 Air Quality Permit to Install and Renewable Operating Permit

The Air Quality Division (AQD) within EGLE supports efforts to maintain clean air and minimize adverse impacts on public health and the environment. This division is responsible for issuing permits to install ensuring that all new or modified sources of air pollution will not have a detrimental impact on human health, human welfare, or the environment, and will comply with all applicable state and federal requirements. The Renewable Operating Permits are issued to ensure that all applicable air pollution control requirements for a major source are consolidated and clarified in a single comprehensive document.

Construction of the Oakwood CSO RTB facility required an Air Quality Permit, but not a Renewable Operating Permit. No modifications to the odor control system at Oakwood are included in the scope of this project, so an Air Quality permit should not be required. Likewise, no Air Quality permit was required for construction of the Leib facility, and no Renewable Operating permit.

4.0 City of Detroit Permits, Reviews or Approvals

4.1 Building Permit(s)

The Building, Safety Engineering, and Environmental Department (BSEED) enforces construction, property maintenance, environmental compliance and zoning codes, for the City of Detroit. Plans and specifications must be submitted to this department for review to ensure that the project complies with City of Detroit adopted ordinances and codes. This department is responsible for issuing the building permit approving modifications performed at the Oakwood and Leib facilities.

The process for applying for a BSEED building permit is completed through City of Detroit eLAPS system. For each permit application, the applicant must complete the permit application and submit the permit review fee via the eLaps system. submit the following required information as part of the permitting process. Plans must be submitted for review via a separate system called ProjectDox (ePLANS) after the application has been submitted. A ProjectDox account is automatically created for a user if that applicant does not already have one registered with their email address. For users with an existing account under the same email address, the submitted permit application will be linked to their existing account automatically. Additional information regarding plan submission is transmitted to the applicant automatically after the permit application is submitted. After plans are submitted, the documents are automatically transmitted to the appropriate internal reviewing agencies and departments based on the content of the application and the selections made on the application forms.

Each facility will require its own building permit, and an individual permit application should be submitted for both the Oakwood CSO RTB facility and the Leib CSO SDF. Required documents for each submittal may include plans, specifications, and calculations, depending on the scope of the alterations at each facility.

GLWA will obtain the building permit, however, the sub-contractors responsible for the various trades may be required to obtain the trade permits for electrical, mechanical, plumbing and heating.

4.2 Right-of-Way / Encroachment Permit

The scope of work at the Leib CSO SDF includes expanding the site footprint to encompass multiple adjacent empty lots and an adjoining alley. This work will require an approved request to change the status of the right of way for the alley.

The request must include the following required information:

- **Completed application form.** The application form must be submitted via the City of Detroit Right of War Management Account.
- **Letter of Intent.** A letter must be submitted addressed to the City of Detroit that includes the name/contact info of the applicant and a detailed summary of the proposal.

- **Letter of support.** Any vacation of the right of way requires proper community engagement with all adjacent landowners. The applicant must obtain a letter of support from all adjacent landowners before the application can be accepted. Blocks that are residential only, may obtain signatures of 2/3 or 66% of adjacent residential owners. A standard petition form is available for collecting signatures from residential owners. If the proposal for vacation results in the creation of a dead-end right-of-way or alley the application will be rejected.
- **Site plan.** A site plan is typically required, but this requirement is waived for residential alleys.
- **Utility Plan.** If the right-of-way will be vacated and not converted to an easement, any public utilities located in the right of way must be abandoned or relocated. The applicant must provide a utility plan showing how assets located in the street/alley will be changed (abandoned, relocated, or new easements to access utility assets).

The City of Detroit Department of public works (DPW) is tasked with conducting a review for all requests to change the status of a right-of-way. During the review, a notice will be sent out to various utility companies and City Departments. Completion of the review process takes approximately 6 to 10 weeks. Upon completion of the review, a recommendation will be made to City Council and a hearing will be scheduled.

5.0 Wayne County Requirements, Reviews or Approvals

5.1 Traffic Control

Construction activity related to this project may impact traffic in the area, and some of the traffic planning may impact the way the traffic in Wayne County is rerouted. Therefore, it may be necessary to inform the Wayne County Road Commission of construction activities with the potential to impact traffic. Their approval may not be required, but a plan should be submitted to them for informational purposes. The Traffic Operation Office can be contacted at the following number:

Traffic Operation Office:

Tel: 1-888-762-3273

5.2 Soil Erosion and Sedimentation Control Permit

The Wayne County Department of Public Services (DPS) requires a permit for the following activities under Wayne County DPS jurisdiction:

1. Crossing, modifying or discharging storm water to a County Drain
2. Connecting into or otherwise altering a County sanitary interceptor sewer
3. Design and construction of wastewater facilities such as a sanitary sewer, pumping station, with a direct connection to a Wayne County sewer.

TM-28 Permitting and Regulatory Requirements

June 1, 2023

Page 12

4. Any earth change/disturbance over 1 acre in size and/or within 500 feet of a water of the state. (Soil Erosion Permit)

Work at the Oakwood CSO RTB facility and the Leib SDF will not require work on any stormwater drains or sewers that would require permits as described in bullets 1-3. However, site improvements at one or both sites may trigger requirements for a soil erosion permit. If it is determined that a SESC permit is required for this project, the application must include the following information:

1. Completed application form.
2. Three sets of plans and specifications for the Soil Erosion and Sedimentation Control plans.
3. Payment of application fee. and performance deposit.
4. Performance deposit for maintenance of the finished project up to and beyond project completion

The application packaged must be submitted 1 month prior to the project startup. The information must be submitted to:

Land Resource Management Division of the Department of Public Services
3600 Commerce Court
Building E
Wayne, Michigan 48184
Ph: 734-595-6504 x2008

5.3 Special Hauling and Transportation Permits

Wayne County DPS, Roads Division is responsible for issuing special hauling and transportation permits and enforcement of oversize and overweight vehicles. The general contractor will need to obtain special hauling and transportation permits if any are required for construction of this project.

Permits are issued by:

Wayne County Department of Public Services
Roads Division - Weighmaster Office
Central Maintenance Yard
29900 Goddard Extension
Romulus, MI 48242
Ph: 734-955-2363

"This Opinion of Probable Construction Cost is produced in accordance with CDM Smith's Firmwide Quality policies and best practices as described in CDM Smith's Estimating Manual Dated 01/03/12 Section 10 titled Quality Control. I hereby acknowledge that the Cost Estimating policies and procedures were followed in preparation of the Opinion of Probable Cost".

Reviewed by	Paul Damon
Review Date	6/13/2023
Delivered Date	6/13/2023
Notes	This is an Opinion of Probable Construction Cost only, as defined by the documents provided at the level of design indicated above. CDM Smith has no control over the cost of labor, materials, equipment, or services furnished, over schedules, over contractor's methods of determining prices, competitive bidding (at least 3 each - both prime bidders and major subcontractors), market conditions or negotiating terms. CDM Smith does not guarantee that this opinion will not vary from actual cost, or contractor's bids. There are not any costs provided for: Change Orders, Design Engineering, Construction Oversight, Client Costs, Finance or Funding Costs, Legal Fees, Land Acquisition or temporary/permanent Easements, Operations, or any other costs associated with this project that are not specifically part of the bidding contractor's proposed scope. This OPCC shall remain valid for 30 days. Beyond this date, CDM Constructors should be notified of design changes. The estimate will also be reviewed to reflect current market conditions. Assumptions: No rock excavation is required. Only nominal dewatering is needed. No consideration for contaminated soils or hazardous materials is included (i.e. asbestos, lead, etc).

"This Opinion of Probable Construction Cost is produced in accordance with CDM Smith's Firmwide Quality policies and best practices as described in CDM Smith's Estimating Manual Dated 01/03/12 Section 10 titled Quality Control. I hereby acknowledge that the Cost Estimating policies and procedures were followed in preparation of the Opinion of Probable Cost".

4. Process Overview

4.1 General Combined Sewer Overflow Facility Descriptions

The Great Lakes Water Authority (GLWA) operates and maintains nine combined sewer overflow (CSO) facilities. The primary function of the CSO facilities is to screen, settle, skim, and disinfect combined sewer/storm water during rain events before discharge to the receiving water body or return captured water to the Wastewater Resource Recovery Facility (WRRF) for further treatment. These CSO facilities play a vital role in keeping combined sewer water out of residents of the City of Detroit's basements and protecting public health and the environment. All facilities must meet discharge requirements contained in GLWA's National Pollutant Discharge Elimination System (NPDES) permit. Detailed facility descriptions are provided in the following sections.

There are two types of CSO facilities: Retention Treatment Basins (RTBs) and Screening and Disinfection Facilities (SDFs). Both facilities provide screening and disinfection. The RTB provides dedicated settling within a retention basin. The SDFs provide contact time for disinfection within effluent conduits prior to discharge to the river. The effluent conduits are up to 1 mile long.

Table 4-1 presents key design criteria and general information for each facility.

4.2 Project Overview

This project consists of three main activities, which consist of the following:

- Asset Management Planning (Scheduled Replacement Plan)
- Performance Based Planning (Facilities Assessment)
- 20-Year Capital Improvement and Capital Outlay Planning

The three main activities and their relationship is demonstrated in Figure 4-1 and described in Sections 4.2.1 through 4.2.3.

Table 4-1. Key Design Criteria and General Information for GLWA’s CSO Facilities

	Baby Creek	Belle Isle	Conner Creek	Hubbell Southfield	Leib	Oakwood	Puritan-Fenkell	Seven Mile	St. Aubin
Facility Abbreviation	BC	BLI	CON	HS	LEIB	OKW	PF	SM	STA

Year of Startup	2005	2007	2005	1996	2002	2012	1996	1997	2002
Hydraulic Capacity (cfs)	5,100	33	13,963	3,200	2,000	1,660	845	655	310
River Level Basis for Hydraulic Capacity (Detroit Datum)	92.0	Not influenced by river elevation	97.5	102.0	Not influenced by river elevation	N/A	129.0	135.2	Documentation not found
Treatment Capacity ^a (cfs)	5,100	33	13,963/ 13,262 ^b	3,200/ 2,200 ^c	1,550	1,660	845	655	250
Storage Volume (MG)	3.0	0.3	30	22	9.9	9	2.8	2.2	2.4
Screen Type (size of slot or opening)	Perforated Plate (6-mm)	Perforated Plate (6-mm)	Bar Screen (1.5-inch)	Bar Screen (1.5-inch)	Raked Vertical and Horizontal Bar Screens (4-mm)	Perforated Plate (6-mm)	Bar Screen (0.5-inch)	Bar Screen (0.5-inch)	Raked Vertical Bar Screens (4-mm)
Disinfectant Type	Liquid Sodium Hypochlorite (NaOCl)								
Receiving Water Body	Rouge River	Detroit River	Detroit River	Rouge River	Detroit River	Rouge River	Rouge River	Rouge River	Detroit River

^a Treatment capacity refers to the design capacity of the screening and disinfection systems.
^b Based on Conner Creek Basis of Design report, the screening capacity is 13,963 cfs and disinfection capacity is 13,262 cfs.
^c Based on Hubbell Southfield O&M Manual, the disinfection capacity is 2,200 cfs. The screening capacity is not specifically listed and is assumed to be equal to the hydraulic capacity.

Notes:
cfs = cubic feet per second
MG = million gallon(s)
mm = millimeter(s)
N/A = not applicable
NaOCl = sodium hypochlorite
O&M = operation and maintenance

Figure 4-1. Relationship of Main Project Activities

4.2.1 Asset Management Planning (Scheduled Replacement Plan)

The Asset Management Planning (Scheduled Replacement Plan) is further described and the work was completed in Volume 3 – Asset Audit, Condition Assessment, FMEAs, and Scheduled Replacement Plan. This portion of the work focused on the existing GLWA CSO assets, populated asset information into GLWA's Computerized Maintenance Management System (CMMS) Oracle Work and Asset Management (WAM), gathered asset condition and depreciation information, and then utilized a mathematical model to determine when an asset should be replaced.

The Scheduled Replacement Plan (SRP) is an output of the SRP Model and is a listing of asset replacements and their costs over a 20-year planning period. The SRP utilizes the condition assessment results and asset information to calculate a scheduled replacement plan for each asset. The SRP information is then compared to the Facilities Assessment information to help make decisions on selection of Facilities Assessment alternatives, selected alternative implementation date, and possible bundling of alternatives into larger projects.

The SRP is strictly identifying when an asset should be replaced. This replacement is in-kind or with the current version, often the case of control systems. The SRP does not take into account future conditions such as regulatory change or increased/decreased flows. As shown in Figure 4-1, the SRP information is then coordinated with the Facilities Assessment to avoid duplication of budgets and to optimize bundling and scheduling of replacements and/or projects, while considering both existing and future asset needs.

The work completed in Volume 3 - Asset Audit, Condition Assessment, FMEAs, and Schedule Replacement Plan, specifically the SRP, is the first work completed within the overall CSO CS-299 project. This is the foundation of the condition and replacement of existing assets. This information will be pulled into Volume 2 – Facilities Assessment and used to optimize the overall delivery of existing asset replacement and Facilities Assessment projects. In this process, information in Volume 3 may become out of date if Volume 2 optimizes timing of the scheduled replacement of existing assets due to the Facilities Assessment. Therefore, Volume 3 information may not match the final information found in Volume 2.

4.2.2 Performance Based Planning (Facilities Assessment)

The Performance Based Planning (Facilities Assessment) is further described in this Volume 2 – Facilities Assessment. This portion of the work focuses on the current and future needs of the GLWA CSO Facilities such as improving Operations & Maintenance (O&M), increasing safety, standardizing equipment, anticipated flow requirements, and anticipated regulatory requirements.

Within the Facilities Assessment, site reviews of assets, interviews of O&M staff, and evaluation of current and reasonably anticipated future requirements of the CSO Facilities occurred. This resulted in a list of Facility Needs which should be addressed. Alternatives were developed to address these needs and generally include a Do Nothing alternative and one or more implementation alternatives. Each alternative was scored with non-economic benefit rankings and those benefits were compared to the Net Present Value (NPV) of the alternative. The NPV consists of the alternative's capital cost and annual operations and maintenance cost. The best value alternative consisted of the alternative with the lowest NPV/benefit ratio, which indicates the least amount of money required for the largest benefit.

Generally, the best value alternative was the selected alternative which moved on to Capital Improvement Plan (CIP) consideration. However, occasionally some alternatives had very similar NPV/benefit ratios or had external non-quantified benefits and therefore the best value alternative may not have been selected.

Once the Facilities Assessment alternatives were selected and a project identified, consideration of the accompanying assets from the SRP was completed. Some Facilities Assessment alternatives offered enhancements to existing assets or new assets and some alternatives offered replacement of existing assets. Therefore, consideration of the SRP was critical to avoid double budgeting of assets (replacement and needs) and to develop optimal bundling and scheduling of alternatives and projects to maximize the value of the existing assets. For example, the enhancement of a disinfection system should consider the condition of the existing disinfection system and, if appropriate, the enhancement implementation schedule should coincide with maximizing the life of the existing disinfection system.

The work completed in Volume 2 – Facilities Assessment, is the second phase of work completed with the overall CSO CS-299 project. This is the foundation of the facility performance needs and is impacted by the existing condition of assets and the scheduled replacement plan. Volume 2 – Facilities Assessment will optimize the facility needs and scheduled replacement plan and develop the 20-year CIP and 20-year Capital Outlay Plan on a Facility by Facility basis. This information will ultimately proceed to the Volume 1 – Project Information and Capital Improvement and Capital Outlay Plan.

4.2.3 20-Year Capital Improvement and Capital Outlay Planning

Following the development of the Facilities Assessment and SRP, individual CSO Facility 20-year CIPs and 20-year Capital Outlay Plans were created. This process is further described in this Volume 2 – Facilities Assessment report.

Projects for individual CSO Facilities were bundled and scheduled, and a 20-year CIP was developed. These nine 20-year CIPs are contained in this report in the following sections below. The intent of this report is to develop the nine individual CIPs.

Within the Facilities Assessment, a Capital Outlay Plan is developed for each CSO Facility. This plan was developed following the development of the specific CSO Facility CIP. Assets identified in the SRP, that are not being replaced in the Facilities Assessment selected alternatives, make it into the Capital Outlay Plan. Occasionally, a Facilities Assessment selected alternative may be of low complexity, low capital cost, and/or impacted with asset replacements and, therefore, may be included in the Capital Outlay Plan and not the CIP.

4.3 Purpose of Multi-Disciplinary Facilities Assessment

The purpose of this Multi-Disciplinary Facilities Assessment report is to document the identified improvements or needs at GLWA's nine CSO Control Facilities. A facility need is a required or desired improvement to meet current or anticipated changes to the CSO system such as regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease operation and maintenance (O&M).

Jacobs, in collaboration with GLWA staff, identified and evaluated these needs, developed total project capital costs, and provided information for needs prioritization through GLWA's business case evaluation process. The Facilities Assessment projects, along with projects from the Scheduled Replacement Plan (SRP), described further in the following section, will be incorporated into the CIP or Capital Outlay Plan.

4.4 Approach for Multi-Disciplinary Facilities Assessment

Jacobs Consultants, Inc (Jacobs) assembled a team of discipline-specific engineers to help identify and evaluate improvements at each CSO facility. The disciplines for this assessment included:

- Screening

- Disinfection
- Odor Control
- Flushing and Dewatering
- Heating, Ventilation, and Air Conditioning (HVAC) and Plumbing
- Electrical
- Instrumentation and Control (I&C)
- Site
- Architectural
- Safety
- Supporting Infrastructure
- Sanitary and Storm Pumping, if applicable

The needs were identified through the following activities:

- Review of the Wastewater Master Plan (WWMP) for any planned increased/decreased flows at each facility and the potential need for increased facility capacity or modified operation (i.e., RTBs converted to capture-only basins). The WWMP was completed by CDM Smith Inc. in 2020.
- Discipline-specific meetings with GLWA CSO O&M staff to obtain input on needs and issues within the facilities
- Observations during site visits by Jacobs team staff members
- Review of maintenance work orders from WAM
- Review of supervisory control and data acquisition (SCADA) data
- Review of original equipment manufacturer (OEM) condition assessments conducted under CS-299
- Projects to address the identified needs and issues were developed with two or more alternatives. The approach for alternatives evaluation is described in Section 4.7.

4.5 Organization of Multi-Disciplinary Facilities Assessment

The Multidisciplinary Facilities Assessment is organized by facility (in alphabetical order of facility name). The Facilities Assessment starts at Section 4. Section 4 provides the process overview for the Facilities Assessment and how the work was performed. Section 5 provides the evaluation of issues that are common to multiple facilities, such as standardized chemical feed system replacement. In an effort to reduce repetition, these issues are described once in this section and referred to in the facility-by-facility assessments, where applicable.

Sections 6 through 14 include the facility-by-facility assessment of needs. For each facility assessment, the needs are addressed by discipline in the order presented in Section 4.4.

4.6 Coordination with Scheduled Replacement Plan

In conjunction with the Multi-Disciplinary Facilities Assessment, Jacobs reviewed existing WAM data, as-built record drawings, O&M manuals, and met with GLWA O&M staff to identify assets, develop an asset hierarchy, and populate WAM with updated or new asset information. With current asset information established, GLWA and Jacobs collaboratively identified how condition assessments would be performed, either visually or detailed. The visual condition assessment was performed whether the asset was operating or not. Therefore, this was a less intensive condition assessment and a method commonly employed on lower risk assets. The detailed condition assessment was performed on operating assets and, depending on asset type, included such items as vibration, temperature, voltage, and amperage.

Jacobs performed onsite visual and detailed condition assessments of approximately 3,200 assets. This resulted in an asset condition score of 1 through 5, with 1 being nearly new and 5 being extremely poor or not operating. Utilizing the asset condition score, along with additional asset information such as useful life, install date, and replacement cost, Jacobs was able to calculate the asset's scheduled replacement.

The SRP consists of all the CSO assets and their calculated individual replacement date and costs. While a robust SRP following Asset Management best practices is highly important to balance asset risk and expenditures, the SRP process has a very limited ability to address future needs, such as those mentioned above and consisting of regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease O&M.

The SRP process and the Multi-Disciplinary Facilities Assessment report need to be coordinated to avoid excessive expenditures as well as balancing the upgrading of good condition assets. Once the Multi-Disciplinary Facilities Assessment projects are identified, projects that are directly impacting existing assets will be noted and linked to the asset. This will pull all information together so that GLWA staff and Jacobs can develop the prioritized projects for the CIP. For example, see Table 4-2, which demonstrates how decisions might be made based on the Facilities Assessment and SRP information.

Table 4-2. Example of Facilities Assessment and SRP Interaction

Facilities Assessment		Scheduled Replacement Plan		Recommendation
Description	Need Date	Condition	Replacement Date	
Project No. 1	2021	2	2035	Implement Facilities Assessment Project
Project No. 2	2025	5	2021	Implement SRP Project
Project No. 3	None Identified	3	2024	Implement SRP Project

The prioritization of the Facilities Assessment and SRP projects into the CIP may result in some assets in good condition being replaced early as in Project No. 1 above or some Facilities Assessment projects being implemented sooner based on corresponding poor condition assets such as in Project No. 2. The Facilities Assessment and SRP coordination process will be a manual and iterative process, however it is benefited by the work being completed concurrently.

Finally, Project No. 3 illustrates a project or asset that is not included in the Facilities Assessment and will ultimately be replaced as part of the SRP. As such, the intent of the Facilities Assessment is not to evaluate the replacement of every asset, especially those that will be replaced in-kind. Rather, the Facilities Assessment focuses on those needs associated with new regulatory requirements, hydraulic changes, health and safety, equipment standardization, and/or ease O&M.

4.7 Alternatives Evaluation Approach

Once needs were identified, projects were developed, and each project consisted of several types of alternatives for consideration:

- Do Nothing Alternative – replace existing assets in-kind or do not add enhancement assets
- Improvement Alternative – replace/improve existing assets with new technology or approach (includes standardization). This alternative is benefited by a comparison to the Do Nothing alternative which includes existing asset information.

- Improvement Alternative – enhance existing facility performance by adding new assets. This alternative is not benefited by a comparison to the Do Nothing alternative.

4.7.1 NPV/Benefit Ratio

To evaluate alternatives, a best value approach was established. This approach considers the non-economic benefit scoring of each alternative along with the economic Net Present Value (NPV) of each alternative. Then the ratio of NPV to benefit can be determined and an alternative with the lowest NPV/benefit ratio, is the best value alternative.

The non-economic benefits that were considered include:

- Benefit #1 – Health and Safety
- Benefit #2 - Water Quality and Compliance
- Benefit #3 – Capacity Enhancement
- Benefit #4 - Component Performance
- Benefit #5 - O&M Ease

These non-economic benefits were ranked on a scale of 1 to 5 for each benefit and each alternative, with the least benefit being 1 and greatest benefit being 5. When considering the benefit score, the actual number is not as important as the relationship of the scores between alternatives. For example, an alternative that has a significantly greater benefit should be scored accordingly with regards to other alternatives.

The NPV is determined by understanding the alternatives immediate capital cost along with the projected annual O&M cost. For several projects, the differential in O&M costs between alternatives is negligible so for simplicity, the alternatives did not include O&M costs in the NPV, as it would not change the results of the best value alternative.

This best value alternative works very well to defend and justify project alternative selections. However, occasionally additional external factors or the scale of the NPV versus the scale of the non-economic benefits do not align which results in the NPV/benefit ratio not being the best method of selecting an alternative. In those cases, engineering judgement and knowledge of the CSO facility and needs were utilized to select an alternative.

4.7.2 Do Nothing Alternative

Alternatives generally consisted of improvements to the facility but also considered a Do Nothing alternative. The Do Nothing alternative typically consists of pulling the SRP information for the existing assets associated with the Facilities Assessment project. This information contains total replacement costs of the associated assets. The Do Nothing alternative was then given benefit and NPV scores, and an NPV/benefit ratio was developed and considered against improvement alternatives.

Comparing the NPV/benefit ratios of the Do Nothing alternative against the improvement alternatives helped guide the selection of the best value alternative. In some cases, the improvement alternative was selected and, in some cases, the Do Nothing alternative.

Occasionally the Do Nothing alternative did not relate to existing assets as the project was based strictly on adding new assets. In these cases, the Do Nothing alternative did not have costs or an NPV/benefit ratio and, therefore, a best value alternative was not determined. However, the improvement alternative may have been selected when comparing its NPV/benefit ratio to other alternatives throughout this process and when considering external factors.

The SRP also pulls the information listed below (this information is pulled by assigning the Facilities Assessment project number, for example "BC-DIS-1", to the appropriate assets in the SRP):

- Total number of assets selected
- Maximum Consequence of Failure score of the selected assets
- Average Consequence of Failure score of the selected assets
- Maximum Condition Score of the selected assets
- Average Condition Score of the selected assets
- Maximum Risk Score of the selected assets
- Average Risk Score of the selected assets
- Average Life Expectancy of the selected assets
- Average Replacement Date (based on the condition score) of the selected assets
- Total Replacement Cost of the selected assets

The information listed above for the Do Nothing alternative is extremely helpful in determining the scheduling of projects. For example, when considering the standardization of a chemical feed system, the improvement alternative selected may suggest standardizing the chemical feed system. Then, when considering the asset information of the existing chemical feed system, it may be determined that the existing chemical feed system is projected to reach the end of its useful life in a few years and that time may be the optimal time for chemical feed system standardization.

4.7.3 Improvement Alternative

The improvement alternative typically consists of 1) replacing/improving existing assets with a new technology/ approach or 2) enhancement of the existing facility performance through the addition of new assets.

4.8 Capital Improvement Plan and Capital Outlay Plan Approach

The 20-year CIP and 20-year Capital Outlay Plan approach consists of projects for all nine CSO facilities that are to be debt financed (CIP) or revenue/cash financed (Capital Outlay). The CIP projects generally consists of improvements identified in the Facilities Assessment while the Capital Outlay Plan generally consists of the SRP assets.

4.8.1 Capital Improvement Plan Process Overview

The development of the 20-year CIP is based on the results of the Asset Audit, Asset Condition Assessments, SRP, and the Facilities Assessments. While all of this information influenced the development of the CIP, the greatest influencer is the Facilities Assessments and selected implementation alternatives.

Within the Facilities Assessment, site reviews of assets, interviews of O&M staff, and evaluation of current and reasonably anticipated future requirements of the CSO Facilities occurred. This resulted in a list of Facility Needs which should be addressed. Alternatives were developed to address these needs and generally include a Do Nothing alternative and one or more implementation alternatives. Each alternative was scored with non-economic benefit rankings and those benefits were compared to the Net Present Value (NPV) of the alternative. The NPV consists of the alternative's capital cost and annual O&M cost. The best value alternative consisted of the alternative with the lowest NPV/benefit ratio, which indicates the least amount of money required for the largest benefit.

Generally, the best value alternative was the selected alternative which moved on to CIP consideration. However, occasionally some alternatives had very similar NPV/benefit ratios or had external non-quantified benefits and therefore the best value alternative may not have been selected.

Once the Facilities Assessment alternatives were selected and a project identified, consideration of the accompanying assets from the SRP was completed. Some Facilities Assessment alternatives offered enhancements to existing assets or new assets and some alternatives offered replacement of existing assets. Therefore, consideration of the SRP was critical to avoid double budgeting of assets (replacement and needs) and to develop optimal bundling and scheduling of alternatives and projects to maximize the value of the existing assets. For example, the enhancement of a disinfection system should consider the condition of the existing disinfection system and, if appropriate, the enhancement implementation schedule should coincide with maximizing the life of the existing disinfection system.

4.8.2 Capital Outlay Plan Process Overview

The development of the 20-year Capital Outlay Plan is based on the results of the Asset Audit, Asset Condition Assessments, SRP, and the Facilities Assessments. While all of this information influenced the development of the Capital Outlay Plan, the greatest influencer is the SRP.

Within the Facilities Assessment, a Capital Outlay Plan was developed for each CSO Facility. This plan was developed following the development of the specific CSO Facility CIP. Assets identified in the SRP, that are not being replaced in the Facilities Assessment selected alternatives, make it into the Capital Outlay Plan. Occasionally, a Facilities Assessment selected alternative may be of low complexity, low capital cost, and/or impacted with asset replacements and therefore may be included in the Capital Outlay Plan and not the CIP.

4.9 Capital Cost Estimating Approach

Capital cost estimates were developed for capital improvement projects presented in this Facilities Assessment and for SRP projects (i.e., replace in-kind).

4.9.1 Capital Improvement Project Costs

Capital improvement projects represent those projects that would likely require design and construction assistance by a Professional Engineer and installation/construction by a Contractor. Capital cost estimates (included in Volume 6 – Appendices, Appendix C for all Facilities Assessment projects) used a uniform template with individual construction costs for major components of the project and then typical percentages for planning, design services, services during construction, additional project costs for the contractor, and design and construction contingencies. The total cost presented for each project represents a Total Project Cost. A summary of the cost categories and the associated source of costs is included in Table 4-3.

Table 4-3. Cost Categories for Capital Cost Estimating

Cost Category	Description	Method for Cost Generation
Project Definition, Planning and Preliminary Design	Represents costs for professional services to develop the project definition, planning and preliminary design concepts. Typically, this information would be used in development of the Design Services procurement documents. Budget for this scope is provided for every project, however GLWA staff may choose to complete this scope internally at minimal cost.	5% of Total Construction Cost

Cost Category	Description	Method for Cost Generation
Design Services	Represents costs for professional design services to produce contract documents that can be bid by a Contractor.	The cost of this service is based on a percentage inversely proportional to the total construction cost, with a higher percentage for lower cost projects and a lower percentage for higher cost projects.
Non-Construction Contingency	Contingency for the design phase to include unforeseen issues that need to be included in the design or be evaluated during design.	15% of Total Construction Cost for most projects.
Services During Construction	Represents costs for professional services that are not covered by GLWA staff to provide construction administration services, including submittal reviews, Requests for Information (RFIs), field inspection, material testing, etc.	Similar to Design Services, the cost of this service is based on a percentage inversely proportional to the total construction cost with a higher percentage for lower cost projects and a lower percentage for higher cost projects.
Total Construction Cost	Represents the cost for a Contractor to perform the work, assuming a Design/Bid/Build type of project delivery.	Sum of Project Cost of Work and Additional Project Cost for Construction.
Project Cost of Work	This cost represents the costs for the material, labor, and equipment to construct the scope of work.	Based on vendor quotes, Jacobs construction cost estimating software, and experience.
Additional Project Cost for Construction	Represents the additional costs of the Contractor to manage and deliver the scope of work. Also includes Construction Contingency based on Final Design.	- Contractor Overhead – 8% (of Project Cost of Work, typical for all costs in this category) - Contractor Profit – 5% - General Conditions – 10% - Mobilization/Demobilization – 5% - Insurance – 2% - Performance Bond General – 1% - Performance Bond Electrical – 1%
Construction Contingency Based on Final Design	Contingency (30% for most projects) to cover ancillary items not included in the line item costs and unforeseen conditions that are not known in the project planning phase.	30% of Project Cost of Work for most projects
Total Project Cost		Sum of the Project Definition, Planning & Preliminary Design, Design Services, Services During Construction and the Total Construction Costs

The Total Project Costs represent Class 4 estimates, as defined by the Association for the Advancement of Cost Engineering (AACE) International. The expected range of costs is -30% and +50% from the median value. It should be noted that in providing opinions of cost for projects, Jacobs has no control over performance of third party engineers/contractors; cost or price of labor and materials; unknown or latent conditions of existing equipment or structures that may affect operation or maintenance costs; competitive bidding procedures and market conditions; time or quality of performance by operating personnel or third parties; and other economic and operational factors that may materially affect the ultimate project cost or schedule. Therefore, Jacobs makes no warranty that the actual project costs will not vary from Jacobs opinions or estimates of cost.

4.9.2 Scheduled Replacement Plan Asset Replacement Costs

Replacement costs are provided for every asset in the CSO WAM database. These costs are used to provide capital costs in the SRP. The costs are intended to represent installed costs for the in-kind (or latest version) replacement of each asset. To populate these costs, Jacobs used previously generated costs from the 2013 SRP project (inflated to 2021 dollars), which included costs from Schedule of Values from the original construction project for the CSO basins. Where costs were not available, Jacobs obtained costs from construction cost estimating software or vendor quotes. Table 4-4 provides the mark-ups applied to the unit costs to generate the total replacement cost for each asset.

Table 4-4. Cost Categories for SRP Replacement Costs

Cost Category	Method of Cost Generation
Replacement Cost (including installation)	Previous SRP Replacement costs (inflated to 2021 dollars), construction cost estimating software, and vendor quotes
Engineering and Contingency	30% of replacement cost
Contractor Overhead and Profit	15% of replacement cost

5. Common Needs Among Multiple Facilities

5.1 Introduction

This section provides the evaluation of needs that are common or similar among multiple or all facilities. Disciplines with common needs include Disinfection, Electrical, Instrumentation and Controls (I&C), Structural, and Safety. To reduce repetition, these issues are described once in this section and referred to in the facility-by-facility assessments, where applicable. The review of past Maintenance Work Orders for all assets is included at the end of this section.

5.2 Disinfection

5.2.1 Overview and Review of Current Disinfection Performance

This section describes needs related to disinfection that are common among multiple facilities. Common needs for the disinfection systems at each facility include:

- 1) Replacement of Chemical Feed Systems
- 2) Provide Flow-Paced and Total Residual Chlorine (TRC)-Paced Automatic Chemical Feed
- 3) Reduce Costs Associated with Large Quantity of Chemical Induction Mixers

Table 5-1 provides a summary of the disinfection system at each CSO facility and the disinfection process flow diagrams are included in Volume 6 – Appendices, Appendix G. Table 5-2 provides a summary of the sodium hypochlorite pumps and capacities at each facility.

Table 5-1. Overview of Disinfection Systems

Facility	Type	Install Date	Disinfection System Design Storm Flow (cfs)	Disinfectant Used	Design Feed Strength (% Hypo.)	Max. Dosage at Design Flow (mg/L Cl ₂)	No. of Storage Tanks	Total Vol. of Storage Tanks (gal)	Storage Tank Material	Type of Mixing at Feed Point	Contact Time (min)	No. of Mixers	Model Number/ hp	Manufacturer
Baby Creek	SDF	2006	5,100	Sodium hypochlorite	5	20	4	144,000	Rubber-lined steel	Chemical induction mixers	10	32	SWC15XPL 15 hp	Water Champ
Belle Isle	RTB	2007	33	Sodium hypochlorite	6-8	25	2	2,668	FRP	Chemical induction mixers	10	4	SWC15XP 15 hp	Water Champ
Conner Creek	RTB	2005	13,262	Sodium hypochlorite	10	25	4	380,000	Rubber-lined steel	Chemical induction mixers	5	60	SWC20XP 20 hp	Water Champ
Hubbell-Southfield	RTB	1996	2,200	Sodium hypochlorite	5	10	2	30,000	FRP	Chemical induction mixers	20	3	Series 32 25 hp	Gas Mastrrr
Leib	SDF	2002	1,550	Sodium hypochlorite	7.5	38	2	20,900	FRP	Chemical induction mixers	10	18	SWC15FX 15 hp	Water Champ
Oakwood	RTB	2012	1,660	Sodium hypochlorite	7.5	12	2	23,000	FRP	Diffuser ring	6 w/ 1 basin, 12 w/ 2 basins in service	Hypo added to pump discharge	N/A	N/A
Puritan-Fenkell	RTB	1996	845	Sodium hypochlorite	5	10 @ 845 cfs	2	8,000	FRP	Chemical induction mixers	20	2	SWC5R 5 hp	Water Champ
Seven Mile	RTB	1996	655	Sodium hypochlorite	5	10 @ 655 cfs	2	4,800	FRP	Chemical induction mixers	30	1	Series 32 10 hp	Gas Mastrrr
St. Aubin	SDF	2002	250	Sodium hypochlorite	10	38	2	10,400	FRP	Chemical induction mixers	10	7	SWC7.5FX 7.5 hp	Water Champ

Notes:
% = percent
Cl₂ = chlorine
FRP = fiber-reinforced plastic
hp = horsepower
mg/L = milligram(s) per liter

Table 5-2. Hypochlorite Pump Summary

Facility	Disinfection System Design Storm Flow (cfs)	No. of Pumps	Type of Pump	Capacity of Pump (gpm)	Manufacturer	Drive Type
Baby Creek	5,100	8 Total 2 low-rate 3 mid-rate 3 high-rate	Centrifugal	Low-rate: 0-50 Mid-rate: 0-150 High-rate: 0-400	Corcoran	VFD
Belle Isle	33	3	Diaphragm	10.4	Milton Roy	Adjustable stroke length and speed
Conner Creek	13,262	10	Centrifugal, magnetic drive	197	ITT Goulds Company	Constant speed
Hubbell-Southfield	2,200	5	Gear	10-55	Pulsafeeder (w/ standard coupler/drive)	VFD
Leib	1,550	8 Total 6 low-rate 2 high-rate	Low-rate: Diaphragm High-rate: Centrifugal	Low-rate: 7.6 High-rate: 112	Low-rate: Pulsa Series High-rate: Goulds	VFD
Oakwood	1,660	10 (3 low-rate, 7 high-rate)	Gear	Low-rate: 0-26 High-rate: 1.0-51	Pulsafeeder (with magnetic coupler/drive)	VFD
Puritan-Fenkell	845	4	Gear	20	Liquiflo	VFD
Seven Mile	655	4	Gear	20	Pulsafeeder (w/ standard coupler/drive)	VFD
St. Aubin	250	5 (2 low-rate, 3 high-rate)	Hydraulic diaphragm	Low-rate: 7.6 High-rate: 22.8	Pulsafeeder	VFD

Notes:
gpm = gallon(s) per minute
VFD = variable-frequency drive

NPDES Permit Requirements: The NPDES Permit No. M10022802 contains limits for fecal coliform and goals for TRC for all the CSO facility discharges. The permit specifies event maximum limits for fecal coliform bacteria of 400 counts (cts)/100 milliliter (mL) during the summer and 1000 cts/100 mL during the winter. The event maximum is reported as the geometric mean of all samples taken during an event, provided that three or more samples are collected.

The goals for TRC minimization are to "...operate the CSO retention treatment basins and CSO screening and disinfection facilities in a manner which will provide consistent, effective disinfection while minimizing the discharge of TRC...". The permit specifies operation goals for effluent TRC concentrations of 1.5 mg/L as an event average value and 2.0 mg/L (November 1 – April 30 or "winter") or 3.0 mg/L (May 1 – October 31 or "summer") as event instantaneous maximum values.

The permit defines that an "event" starts when combined sewage is discharged into a facility and ends when effluent flow ceases and does not resume within 24 hours. During an event, grab samples for effluent fecal coliform and TRC are collected every two hours for the first six hours of the discharge and every four hours thereafter for the duration of the discharge. For TRC, the average of all samples in an event is the "Event Average" and the maximum individual sample in an event is the "Event Maximum". On multiday events, the pollutant concentrations for the event are reported on the day the discharge event ends.

Historical Facility Disinfection Performance: Historical facility performance related to disinfection performance from 2016 through 2018 is presented in Volume 6 – Appendices, Appendix D. There are two graphs for each facility:

- 1) Daily Maximum Effluent TRC concentrations
- 2) Effluent Fecal Coliform and Average TRC concentrations

Effluent performance was assessed by comparing the reported event geometric mean fecal coliform concentrations to permit limits and the reported maximum and average TRC measurements to the permit operation goals. Upon review of the TRC data, it was apparent that the measurements were *daily* average and maximum measurements, rather than *event* average and maximum values. Additionally, there were several instances when the recorded maximum TRC value was less than the recorded average TRC value. In such cases, the dataset provided was checked against the Daily Monitoring Reports submitted to Environment, Great Lakes, and Energy (EGLE), and it was determined that the recorded values were simply switched. These errors were corrected by listing the greater value as the daily maximum measurement and the lesser value as the daily average measurement.

A summary of the findings and observations from this evaluation are provided in the following list:

- 1) The fecal coliform limit is typically met for every event, with a few exceptions. The facilities exceeding the limits and the corresponding number of times were as follows: Conner Creek (1), Leib (1), St. Aubin (2), and Baby Creek (2).
- 2) The summer and winter maximum effluent TRC goals of 2 and 3 mg/L are typically met. The SDFs appear to have slightly higher maximum values than the RTBs.
- 3) The operational goal for average TRC of 1.5 mg/L is typically exceeded for all facilities that discharge. This is likely due to the variable nature of CSO influent water quality, the fact that the operators first priority is to achieve permit compliance for fecal coliform, and the lack of automated chemical feed pacing.
- 4) There was no discharge from Puritan-Fenkell or Seven Mile during this period, therefore, the figures indicate "No Data Collected."

5.2.2 Replace Chemical Feed System

5.2.2.1 Introduction

Based on GLWA personnel input and observations during the site visits, the chemical feed systems at most of the facilities are in need of replacement to address one or more of the following:

- Replace aging, unreliable, and/or expensive to maintain chemical feed pumps and mixers
- Address inaccessible valves and appurtenances due to overly complex flow distribution schemes, and poorly laid out piping
- Increase turndown to not overdose during the more typical storm events while providing capacity for the infrequent peak instantaneous design storm flows
- Simplify the chemical feed system to improve manual operations should automated components be unavailable
- Ensure appropriate flow splitting to multiple mixers and diffusers in a given mixing zone including:
 - Replace old and unreliable back pressure valves to each mixer and diffuser
 - Provide a means of measuring pressure to verify back pressure valves are functioning properly and set equally
 - Provide flow indication for visual verification that flow is occurring to each location.

Additional facility specific needs are discussed in the facility-by-facility evaluation in the following sections. The evaluation and identification of chemical feed system alternatives for each facility are presented here and referenced in the facility-by-facility section because this section applies to most facilities.

5.2.2.2 Chemical Feed System Sizing

Based on GLWA observations and historical storm events, the chemical feed systems are generally oversized. The conservative sizing of chemical feed pump capacities is a result of the original facility design storm flows being greater than what has been observed as well as conservative assumptions on the required chlorine dose to meet permit fecal coliform requirements. Turndown of the oversized chemical feed system is exacerbated at Conner Creek where reliability issues with isolation gates results in flow being distributed across all bays regardless of how small the wet weather event is. The lack of isolation gates into the mixing zones results in a similar situation at Leib. Oversized chemical feed systems make it difficult to control dosing during smaller events. This increases the risk of exceeding the operational goals for TRC. Relevant information from past CSO facility studies was considered for sizing the chemical feed pumps for purposes of developing a capital cost budget.

The CSO facilities were originally designed based on modeled peak flow for a 10-year recurrence, 1-hour rainfall. Although continuous flow measurement records are not available, the design capacity at most or all of the facilities has never been reached based on available flow data and observations by GLWA personnel. Collection system modeling tools have improved since the modeling used for the design of these facilities. The most recent design storm results were obtained from the December 2019 Existing Conditions version of the Regional Wastewater Collection System model developed for the 2019 GLWA WWMP. The current predicted 10-year, 1-hour storm flows and the ratio of those flows as a percent of the original design flows are presented in Table 5-3.

Table 5-3. Comparison of Original and Current Predicted CSO Facility Design Storm Peak Flow Rates (10-Year, 1-Hour Flow Rates)

Facility	BC	BLI	CON	HS	Leib	OKW	PF	SM	STA
Original Predicted Facility Design Storm Peak Flow (cfs)	5,100	33	13,262	3,000 ^a	1,550	1,660	655 ^a	493 ^a	250
Current Predicted Facility Design Storm Peak Flow (cfs)	1,661	37	2,569	1,501	194	475	136	82	235
Ratio of Current to Originally Predicted Storm Flows (%)	33%	111%	19%	Not a comparable storm comparison	13%	29%	Not a comparable storm comparison	Not a comparable storm comparison	94%

^a The O&M manual provides the "10-year" Design Flow for 3.5 inch storm. It is assumed this is the 10-year, 24-hour storm event, since the 10-year, 1-hour storm is about 1.8 inches.

For the larger facilities with comparable design storms (i.e., Baby Creek, Conner Creek, Leib, and Oakwood) the predicted flows are less than half what was predicted for the same storm event when the facilities were designed. The generally lower flow predictions are partially explainable by:

- Recently modeled flows are in terms of peak hour while the original modeled flows were a shorter time increment
- The percent imperviousness of many of the service areas has decreased, thus contributing to less runoff
- More conservative assumptions in the original model

However, two concerns prevent revising the chemical feed system sizing based on the recent 10-year 1-hour modeling as follows:

- 1) There have been issues calibrating the model predicted flows to actual measured flows from storm events
- 2) The model predicted flows are less than past observed peak hour flows

At Conner Creek, which is the largest facility, the recently modeled 10-year 1-hour flow is only 19 percent of the original modeled flow. This would indicate that the facility is significantly oversized. However, the WWMP evaluated the flow distribution of 78 storms, 25 from 2005 to January of 2008 from the "Conner Creek CSO Basin Final Evaluation Report", and 53 from 2010 to 2014 discharge records, and found the peak flow at Conner Creek was 8,600 cfs and the average peak flow was 2,600 cfs. Thus, the modeled peak 10-year 1-hour event of 2,569 cfs was essentially equal to the average peak flow and significantly less than the historical peak from the 78 storms analyzed. The 8,600 cfs peak flow identified in the WWMP corresponds to 65 percent of the facility's design capacity. Based on the years analyzed, it would appear that the original design capacity of Conner Creek is overly conservative. However, the more recent modeled peak 10-year 1-hour flow does not appear to be conservative enough. Unfortunately, complete flow data is not available for the last 10 years at the CSO facilities to allow evaluation of the peak 10-year flow. Due to the absence of historical data and the fact that the recently modeled 10-year 1-hour event does not appear sufficiently conservative for design of disinfection facilities, the original facility design capacities will be used for sizing the chemical feed systems for capital budgeting. As additional flow data

becomes available with upgrades to flow measurement and recording, more modeling calibrated to actual flows could be considered during design to avoid oversizing the chemical feed system.

The selected design dose is also important to chemical feed system sizing. The original design doses vary from 10 mg/L as Cl_2 to 38 mg/L between CSO facilities. Experience at other CSO facilities indicates that the high doses assumed at some facilities are overly conservative considering both the improbability of needing the peak dose concurrent with peak flow when fecal coliform concentrations are likely diluted, and test data that would indicate diminishing disinfection benefits above certain doses.

For this evaluation under CS-299, a dose of 20 mg/L was assumed for all facilities except St. Aubin. A dose of 25 mg/L was assumed for St. Aubin because this facility had the highest average dose for the four largest storms evaluated from 2016 through 2018 and because a relatively recent report by another consultant assumed 24 mg/L. However, it is suspected that the higher dosing at St. Aubin was a result of turndown issues and lack of an automated control system and thus conservative. In addition, planning and budgeting for St. Aubin's disinfection system is not required because there is an ongoing design by another consultant at St. Aubin. Therefore, dosing requirements at St. Aubin are not further evaluated in this Facilities Assessment. The dose assumptions are believed to be sufficiently conservative for sizing the chemical feed systems for capital budgeting, especially when used in conjunction with the design peak flow rate. It may be appropriate to assume less conservative doses during design because oversizing the chemical feed system can lead to turndown issues for typical storm events.

The third most significant factor affecting chemical feed system sizing is the sodium hypochlorite strength. The sodium hypochlorite strength can vary either due to degradation or intentional dilution of a new delivery of sodium hypochlorite done to slow the degradation of sodium hypochlorite. The degradation of sodium hypochlorite is unique compared to most other chemicals used in wastewater treatment. The lower the sodium hypochlorite strength the larger the chemical feed system needs to be. The sodium hypochlorite strength is important because twice the feed rate is required for the same TRC if the sodium hypochlorite has degraded from 10 percent to 5 percent. An evaluation of sodium hypochlorite strength reported in recent years for the CSO facilities indicates that the strength has dropped to as low as 2 to 3 percent for all facilities that data was available, except Conner Creek. At Conner Creek the lowest reported strength was 5 percent. The hypochlorite strength has such a significant impact on sizing the chemical feed system that it is important to develop and abide by a policy of replacing the hypochlorite when the strength drops below a certain value. Depending on the quantity stored, this may be achieved by ordering a new delivery and mixing the low strength hypochlorite with the new full strength (e.g., typically on the order of 12.5 percent) hypochlorite. However, if the volume stored will excessively reduce the strength of a new delivery it would be necessary to dispose of the excess hypochlorite. Careful management of hypochlorite can be practiced to minimize the latter. For this evaluation under CS-299, a value of 5 percent was assumed as the minimum strength that sodium hypochlorite would be managed to for sizing the chemical feed pumps for purposes of developing a capital cost budget.

The assumed pump sizing is dependent on the sodium hypochlorite distribution approach and is thus presented in Section 5.2.2.4.

5.2.2.3 Chemical Feed System Pump Type

It is recommended that the existing pumps be replaced with either hose pumps (referred to as peristaltic pumps for smaller sizes) or magnetic drive centrifugal pumps. The advantages and disadvantages of these two types of pumps are noted in the following paragraphs. The final decision between the recommended types of pumps shall be determined during design. The preferred type of pump may also depend on what alternative is selected for flow distribution of sodium hypochlorite.

Hose Pumps: The advantages of hose pumps are listed in the following bullets:

- High turndown: With a totally enclosed non-ventilated motor and 60:1 variable-frequency drive (VFD), the hose pump maximum and minimum acceptable revolutions per minute (rpms) become the limiting factor. Higher than 20:1 turn down can be achieved by designing around atypically high rpms for the design peak flow storm events if this condition is expected to be rare. Turndowns on the order of the 60:1 VFD turndown may be possible by this approach.
- Positive displacement for accurate and repeatable metering
- Self-priming and suction lift capability of up to 30 ft thereby allowing full tank drawdown and allowing the pumps to be elevated on pads for spill protection
- Can pump air during priming, and sodium hypochlorite off-gassing will not bind the pump
- Hoses readily available for sodium hypochlorite (common application)
- No seals, diaphragms, glands, or exposed components to leak, corrode, or replace
- Eliminates need for check valves, seal water flush systems, and run-dry protection
- Standard parts (hose, bearings) for rehab

The disadvantages of hose pumps are listed in the following bullets:

- Higher initial cost than some other pumps
- Requires hose replacement
- Requires pulsation dampener which GLWA has had O&M issues with elsewhere
- If a hose wears through or bursts before replacement, then components of the pump will be exposed to the corrosive sodium hypochlorite
- Requires bumping the pumps per manufacturer's suggested schedule when idle (i.e., during dry weather and spare pumps) because the rollers compressing a fixed point of the hose for an extended period of time reduces hose life

The largest hose pump offered by Bredel is rated for 317 gallons per minute (gpm) continuous duty.

Magnetic Drive Centrifugal Pumps: The advantages of magnetic drive centrifugal pumps are listed in the following bullets:

- Generally lower initial cost than most pumps suitable for sodium hypochlorite
- Smaller footprint for the capacity than most pumps suitable for sodium hypochlorite
- Magnetic drive eliminates seals and leaks from drive shaft
- Centrifugal pumps are generally low maintenance
- GLWA has favorable experience using this type of pump at Conner Creek
- Eliminates need for pulsation dampeners
- Depending on the flow and head condition, higher capacities generally available compared to hose pumps

The disadvantages of magnetic drive centrifugal pumps are listed in the following bullets:

- Significantly less turndown than a positive displacement pump. This can result in the need for more pumps and potentially pumps of different sizes to cover the required range of flows.

- Not self-priming and less suction lift capability than a positive displacement pump. Therefore, these pumps cannot be elevated above the bottom of the tank as much as self-priming pumps for spill protection, and these pumps may not be able to draw a tank down to empty without supplemental priming provisions. The latter issue adds components and complexity and may decrease reliability. Although there are some self-priming models available, there are far fewer offerings than the standard non-self-priming sizes to cover the required range of flow and head conditions.
- Requires some appurtenances not required with a hose pump (e.g., check valves).
- Cannot run dry.
- Possibility of cavitation.

5.2.2.4 Sodium Hypochlorite Distribution Approach

In conjunction with pump replacement, it is recommended that the piping be replaced, and that the new piping be simplified compared to the current arrangement. Reasons for piping replacement include overly complex piping layouts, inaccessible valves and appurtenances, and failing joints in some facilities (e.g., Baby Creek). It is recommended that piping to and from the pumps be as simple as possible while maintaining necessary flexibility. Adding additional flexibility that is unlikely to be used adds complexity including additional valves to be exercised, the need for additional pressure relief valves wherever sodium hypochlorite off-gas could be trapped and can result in inaccessibility of components which is a common problem at the GLWA facilities. It is recommended that these points be carefully considered as the details of the piping are determined during design. A standardized pump per mixing zone or a standardized manifold approach is recommended for all GLWA CSO facilities. The final decision between the recommended options for sodium hypochlorite distribution should be determined during design considering the advantages and disadvantages. Two recommended options and piping arrangements are presented in the following paragraphs.

Option 1—Standardized Pump Distribution

This option would consist of utilizing a positive displacement pump for each mixing zone. The recommended type of positive displacement pump for this option is a hose pump (or peristaltic pump for smaller capacities) because of the advantages noted in Section 5.2.2.3. Each pump would require a VFD to adjust the dose in response to varying storm flows and chlorine demands. Each pump would pump to one mixing zone. One spare pump, or more if desired, is recommended with a tie-in to each primary pump to provide redundancy to each mixing zone without significantly increasing the complexity of the piping. The proposed configuration is illustrated in Figure 5-1.

Flow to each mixing zone would be split between mixers using back pressure valves. New back pressure valves are recommended to split the flow between injection points (e.g., mixers and or diffusers). A setting of 15 pounds per square inch gauge (psig) is recommended by Evoqua for Water Champ induction mixers. A pressure tap is recommended upstream of each back pressure valve to allow a calibrated pressure gauge to be moved between these taps to allow verification that each back pressure valve is set equally and to adjust the back pressure valve setting if not. A flow meter is also recommended to further verify equal flow splitting and to allow calculation of total flow rate to that mixing zone. Minimization of mixers and feed points is recommended as discussed herein to reduce the number of flow splits with back pressure valves, flow meters, and pressure gauge taps.

Figure 5-1. Standardized Pump Distribution

The advantages and disadvantages of this option are as follows:

Advantages:

- Simple and reliable control strategy with linear relationship between the pump speed and pump output (not reliant on flow meters due to the predictable speed vs. output relationship).
- Proven common approach for chemical dosing that will meet the permit requirements at each facility.
- Higher turndown ability than manifold option. Turndown ability is based on pump capabilities and not limited by instrumentation.
- If automated mode is not functional then manual mode would consist of manual pump speed adjustment for each pump in response to changing storm flow and TRC measurement.

Disadvantages:

- Higher number of pumps
 - Higher capital cost
 - Greater floor space required
 - More maintenance because pumps are higher maintenance than actuators in the manifold option
 - More equipment that could fail
 - More operations of equipment

Option 2 - Standardized Manifold Distribution

This option would be expected to allow a reduced number of pumps at facilities with a large number of mixing zones and would consist of the following: One or more pumps would pump to a manifold. Each pump would be controlled by a VFD. The pumps could be magnetic drive centrifugal or hose pumps. There would be one branch from the manifold for each mixing zone plus a spare connected to each to provide the same redundancy as the spare pump in Option 1. Every mixing zone would have its own flow meter and flow control valve. There would be a modulating pressure control valve on a recycle loop downstream of the manifold that is controlled to a pressure setpoint to ensure sufficient pressure to split flow in the manifold. The pumping rate is set sufficiently in excess of the desired sum of the feed rates to all feed points. Flow in excess of that distributed through the manifold is recycled to the feed pump suction header. The proposed configuration is illustrated in Figure 5-2.

Standard Manifold Distribution

Figure 5-2. Standardized Manifold Distribution

Flow to each mixing zone would be split the same as Option 1, except given there will be a magnetic meter to each mixing zone the flow meters to each mixer or diffuser need not be sophisticated nor connected to SCADA. Therefore, a rudimentary visual flow indicator is recommended upstream of each back pressure valve. The flow indicators will allow a visual confirmation that hypochlorite is being provided to each location and an indication of equal flow splitting. Minimization of mixers and feed points is recommended as discussed herein to reduce the number of flow splits with back pressure valves, flow meters, and pressure gauge taps.

The advantages and disadvantages of this option are as follows:

Advantages:

- Minimizes number of pumps
- Proven approach to flow splitting.
 - Similar design by author has been in operation since the early 1990s at a WRRF.
 - There are many large WRRFs using a large number of flow control valve (FCV)/flow meter combinations to split air between aeration grids and multiple parallel aeration basins based on dissolved oxygen monitoring.
- A low number of pumps, and a flow control valve and flow meter combination per mixing zone, typically will have a lower capital and maintenance cost than a dedicated pump per mixing zone.
- Similar redundancy to a spare pump can be achieved with a spare branch from the manifold that ties into the discharge to each mixing zone from the manifold.

Disadvantages:

- Will require utilization of the number of mixing zones to match the storm flows. For example, a small storm event needs to be contained in one mixing zone while the peak storm event can utilize all mixing zones. This will ease the turndown requirements of the control instrumentation and the overall system.
- Lower turndown than possible with a dedicated peristaltic/hose pump approach. Minimum turndown of at least 16:1 and possibly as high as 26:1 per mixing zone.
 - The estimated maximum achievable turndown is based on a maximum allowable velocity of 8 ft/sec through a pipe and magnetic meter. Above this, noise and potential for cavitation in the flow control valve can become problematic.
 - The estimated maximum achievable turndown is based on a minimum velocity of 0.3 to 0.5 ft/sec. Below this, flow measurement can drop off to zero in magnetic meters and thus not be reliable.
 - Accommodating the required turndown from the infrequent design peak storm capacity to the more typical storm events could be problematic. The acceptability of the maximum achievable turndowns with this approach should be compared to ratios of peak design storm capacity to historical flows for each facility considering this approach.
- Must properly tune actuators at startup for steady valve operation.
- Even with well-tuned actuators, the valves must adjust frequently during a storm event to rapidly changing flows and chlorine demands, and to the influence of adjacent valves that are changing position.
- The pipe sizes required will result in small valves with large and heavy actuators that must be independently supported (i.e., pipe supports for the actuators).
- Must maintain multiple modulating actuators.
- If automated mode is not functional then manual mode would consist of manually adjusting the position of each of the flow control valves in response to changing storm flow and chlorine residual measurement, verifying adequacy and changing as necessary the pumping rate (but fewer pumps than the dedicated pump per mixing zone option), and verifying adequacy and changing as necessary the pressure control valve position to maintain sufficient pressure in the distribution manifold.

- Failure of the pressure control valve actuator would require manual valve adjustment that must be monitored and adjusted as necessary as the storm flow varies.
- Although not a high likelihood of failure, there is more length of common header piping than the dedicated pump option. This is because the hypochlorite is in a common header not only to the pumps but from the pumps to the manifold and on the return loop downstream of the pressure control valve. This common header length can be minimized by locating the manifold in the pump room. A failure in a common header would disrupt disinfection everywhere.

5.2.2.5 Pump Sizing for Capital Budgeting

As discussed herein, the original facility's design peak flow, an assumed dose of 20 mg/L chlorine for all but St. Aubin, and an assumed minimum sodium hypochlorite solution strength of 5 percent was assumed to size chemical feed pumps at each facility for soliciting budgetary pricing from the leading manufacturer of hose pumps for the two recommended options for feed distribution, as shown in Table 5-4 and Table 5-5.

Table 5-4. Option 1 – Pump Sizing for Standardized Pump Distribution

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Number of Prechlorination Pumps	0	0	0	0	1	0	2	1
Size of Each Prechlorination Pumps (gpm)	N/A	N/A	N/A	N/A	100	N/A	24	30
Number of Mixing Zone Pumps (includes one spare)	9	3	11	5	5	9	3	3
Size of Each Mixing Zone Pumps (gpm)	95	2	197	70	58	31	24	23

Table 5-5. Option 2- Pump Sizing for Standardized Manifold Distribution Using Hose Pumps

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Total Number of Pumps (includes one spare)	4	2	8	3	3	3	2	2
Size of Pumps (gpm)	253	5	282	164	115	124	48	47

The lack of turndown and resulting higher number of required pumps prevents the magnetic drive centrifugal pumps from being a recommended type of pump for Option 1. However, magnetic drive centrifugal pumps are a viable alternative for Option 2. Larger magnetic drive centrifugal pumps are available than with hose pumps. Therefore, budgetary pricing with fewer larger magnetic drive centrifugal pumps was solicited for Option 2 as shown in Table 5-6.

Table 5-6. Option 2- Pump Sizing for Standardized Manifold Distribution Using Magnetic Drive Centrifugal Pumps

Facility	BC	BLI	CON	HS	Leib	OKW	PF	STA
Total Number of Pumps (includes one spare)	3	2	6	2	2	2	2	2
Size of Pumps (gpm)	378	5	394	326	230	246	47	46

5.2.2.6 Chemical Feed System Alternative Costs for Identified Alternatives

The capital costs for the identified chemical feed system alternatives, including the replace in-kind alternative, are summarized in Table 5-7. Detailed cost estimates for each facility are provided in Volume 6 – Appendices, Appendix C under each facility.

Table 5-7. Capital Costs for the Pump Distribution and Pump Type Options

Identified Alternatives	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Facility	Replace In-Kind	Standardized Pump Distribution (Option 1) with Hose Pumps	Standardized Manifold Distribution (Option 2) with Magnetic Drive Centrifugal Pumps	Standardized Manifold Distribution (Option 2) with Hose Pumps
Baby Creek	\$1,657,000	\$3,325,000	\$1,237,000	\$2,388,000
Belle Isle	\$235,000	\$382,000	\$274,000	\$264,000
Conner Creek	\$2,919,000	\$5,409,000	\$2,300,000	\$4,369,000
Hubbell-Southfield	\$970,000	\$1,130,000	\$534,000	\$843,000
Leib	\$1,262,000	\$1,724,000	\$901,000	\$1,178,000
Oakwood	\$1,964,000	\$1,332,000	\$443,000	\$886,000
Puritan-Fenkell	\$340,000	\$687,000	\$383,000	\$545,000
Seven Mile	Not evaluated since facility will be converted to a Capture-Only			
St. Aubin	Evaluated under Sodium Hypochlorite Feed and Storage System Improvements. See Section 14.2.2.2.			
Total Capital Costs for All Facilities	\$9,348,000	\$13,989,000	\$6,072,000	\$10,473,000

It should be noted that Alternative 4 is not further included in the evaluation as it is nearly double the cost of Alternate 3 with no additional benefits or performance enhancements.

The following additional improvements to the sizing of the disinfection systems should be addressed for either Alternative 2 or 3, but are especially important if implementing the manifold alternative due to the lower turndown:

- Refine the maximum design flow once sufficient influent flow data is available from improved influent flow monitoring. While 10 years of reliable historical data will not be available in time for replacing the chemical feed systems, reliable influent flow data in conjunction with precipitation data should be used to better calibrate the collection system model. The model can then be used to determine an appropriate design flow once the model accurately predicts flow to a facility for a given precipitation event.
- Consider a lower design dose at peak flow. Monitoring influent bacterial counts versus flow and evaluating the probability of the peak dose being required concurrent with peak flow could further reduce the required pump sizing. A lower dose may be required at the design peak flow if bacterial counts decrease due to dilution with increasing flow. For example, if the required dose at the design peak flow was determined to be only 10 mg/L rather than 20 mg/L, this would allow the hypochlorite pump sizing to be half that assumed. This in turn would allow dosing at a much lower rate during small wet weather events and thereby help address the turndown limitation of the manifold compared to the pump distribution alternative.

5.2.3 Flow-Paced and TRC-Paced Automatic Chemical Feed

5.2.3.1 Introduction

Based on GLWA personnel input and observations during the site visits, the chemical feed systems do not operate in automatic as intended at any of the facilities. GLWA desires a simple, automated chemical feed system that will improve GLWA's ability to meet both fecal coliform criteria and TRC goals. Manual control is undesirable for the following reasons:

- Operation in manual requires frequent manual adjustments in response to varying storm flow.
- Operation in manual requires frequent sampling and analysis of TRC which is time consuming. This reduces available time for monitoring the facility and attending to other O&M needs.
- Except for extreme storm events at the facilities designed for 5 to 10 minutes contact time, the effluent sample points represent too long of a time delay between the hypochlorite dosing point and measuring point. Thus, adjustments in response to the TRC sampling and analyses at the effluent permit compliance point inherently results in poor control.

The considerations for automating chemical feed pacing are presented here and referenced in the facility-by-facility section because this section applies to most facilities.

5.2.3.2 Automated Sodium Hypochlorite Feed Approach

Consistent dosing in response to rapid changes in flow requires flow pacing, and refinement of the dose in response to changes in chlorine demand requires automated adjustment of the target dose through the use of an online TRC analyzer.

The control strategy would be as follows: The operator inputs a starting chlorine dose in terms of mg/L as Cl_2 . The chemical feed rate to that mixing zone would be controlled automatically to achieve that dose based on total facility flow and number of mixing zones in service. Flow splitting between mixers and or diffusers in a given mixing zone would be by non-automated means as described in Section 5.2.2.4 and thus would not be included in the control loop.

The operator will also input a target TRC. A new TRC analyzer sampling slightly downstream of the dose point (e.g., a certain number of minutes downstream at average flow) will be required for this control. The TRC setpoint would be what is desired after complete mixing and the initial rapid chlorine demand. If the measured TRC is less than the setpoint, then the operator entered target dose, still controlled by flow, would be automatically increased to eliminate the difference between the measured TRC and setpoint TRC (i.e., the primary control parameter will be flow pacing to maintain a target dose and the TRC analyzer will be used to adjust the target dose to account for CSO variability). Operator adjustable time delays would also be provided to allow for the adjusted dose to reach the TRC probe before the measurement is used to make the next adjustment to the dose. This approach is anticipated to control both effluent coliform and effluent TRC to a tighter range than possible based on the current manual approach to chemical dosing.
